Follow up —He was well two and a half years later, and the affected side was $^1/_2$ in greater in circumference than the other The costophrenic angle was obliterated, and a bronchogram normal

Case 3 —A man, aged 67, a month before admission developed a lobar pneumonia and was treated with sulphonamides He relapsed and was admitted with a pneumococcal empyema His hæmoglobin was 48% His chest was aspirated on eight occasions and 36 oz of pus removed Culture became sterile in seven days and smears negative in ten days The patient was discharged in four and a half weeks, and returned to work ten weeks after admission

Follow up —Two and a quarter years later he was at work and had a mild cough, as before his empyema. There was slightly diminished expansion of the affected side, but the circumferences were equal Straight radiography and bronchography were normal

Case 4 —A man aged 54, had pneumonia a month before admission. He relapsed after three weeks and was admitted with an empyema, which consisted of thick pus which grew *Strep viridans* Seven aspirations removed 60 oz of pus Culture was sterile in four days and smear negative in twenty days The patient became apyrexial in three weeks, was discharged after eight weeks, and returned to work twelve and a half weeks after admission

Follow up —Two and a quarter years later he was well, apart from a slight morning cough which he had had for many years Physical examination was negative, the costophrenic angle obliterated, and a bronchogram normal ase 19), is not at variance with the findings of other orkers (Marvin and Pastor 1925, Hill 1932, 1933, Weiss nd Baker 1933)

All the cases in which electrocardiographic abnormalities ere observed are summarised in the table

DISCUSSION

Manipulation of the Abdominal Viscera

No alteration in the heart rate, or in the configuration of the cardiograms, was evident in the 11 cases in which traction was applied to abdominal viscera (stomach 8, gall bladder 1, spleen 1, pelvic colon 1) It is clear that if appreciable changes had been recorded, the significance of the findings during manipulation of the vagus nerves would be difficult to evaluate, since some degree of visceral displacement must obviously be associated with this procedure The literature shows that such alterations are always slight and are neither constant, specific, nor predictable In a total of 110 cases Lennox et al (1922) and Marvin et al (1925) observed no abnormal responses On the other hand, alterations in the heart-rate, and the occurrence of an occasional auricular or ventricular extrasystole, have been reported (Ressinger 1927, Maher et al. 1934, Widenhorn et al. 1938, Hodge and Messer 1948) Such changes are particularly prone to follow manipulation of the upper abdominal viscera, the peritoneum, and the mesenteries and uterine attachments Rovenstine and Hershenson

SUMMARY OF ABNORMAL EXPERIMENTAL FINDINGS IN 36 OPERATIONS

Case no	Sex	Age	Cardio-vascular state	Operation	Premedication: Omnopon (gr)	Premedication: Morphine (gr)	Premedication: Scopolamine (gr)	Premedication: Atropine (gr)	Premedication: Premedication induction interval (min)	Anæsthetic: Thiopentone (g)	Anæsthetic: Nitrous oxide	Anæsthetic: Cyclopropane	Anæsthetic: Ether	Anæsthetic: Curare (mg)	Remarks	Operative manipulation	Electrocardiogram

ELECTROCARDIOGRAPHIC FINDINGS DURING OPERATIVE MANIPULATION OF THE VISCERA AND VAGUS NERVES *

A G FREEMAN
M.A , M D Camb
REGISTRAR, MEDICAL UNIT, CARDIFF ROYAL INFIRMARY , LATE PATHOLOGICAL REGISTRAR, BRISTOL ROYAL INFIRMARY

IN recent years operative surgery has offered more scope for studying how the heart beat is affected by manipulation of the viscera and the vagus nerve Pro found cardiac irregularities, and even cardiac arrest, have been observed after manipulation of the intra thoracic contents, especially those involving the myo cardium and the pericardium, and the pleura and hilar region of the lung (Beck and Mantz 1937, Cullen and Rovenstine 1938, Dunlop 1939, Rovenstine and Martin 1941, Burstein 1946, 1949, Burstein and Alexander 1947) It is believed that arrhythmias are commoner when adequate premedication with atropine sulphate is omitted, and to prevent or mitigate them it has been recommended that procaine hydrochloride be injected intravenously, or else be infiltrated into the hilar region or the vagus nerve (Leigh and Belton 1946, Bittrich and Powers 1948, Dennis et al 1948, Burstein et al 1949)

Although electrocardiographic findings following opera tive manipulation of the vagus have been reported by many workers, most of them have limited their investiga- tions to the supracardiac portion of this nerve in the neck and thorax Seeing that vagotomy for peptic ulcer was firmly established by Dragstedt and Owens in 1943, and that by 1948 the American Gastro enterological Association estimated that 8000 vagotomies had been performed (Colp et al 1948), it is remarkable that so few references have been made to its effect on the cardiovascular system

Bradycardia and circulatory failure have been recorded during manipulation of the right vagus over the lower third of the œsophagus (Weeks et al 1946) the patient, a man aged 55, with no previous symptoms or signs of cardiac disease, died almost immediately after the nerve was divided Moore et al (1946) thought that the death of one of their patients forty eight hours after operation may have been due to irritability of the autonomic nervous system setting up vasovagal reflexes

Noble (1947) stated that " the potential hazards of the new vagotomy operation for peptic ulceration must be considered as vagal inhibition is a real threat " Cole et al (1947) also held that the most serious reaction associated with vagotomy is cardiac and respiratory paralysis, and Allen (1947), Lahey (1947), and Moses (1947) have also commented on this effect A sudden fall in blood pressure and a raised pulse rate during vagal resection has been described by Colp et al (1948), while Tanner (1948) reported tachycardia in the twenty four hours following the operation.

On the other hand, some authorities hold that the risk has been exaggerated In 200 transabdominal vagotomies performed by Dragstedt et al (1948) no alterations were noted in the blood pressure, pulse, or respiration rate which might have indicated vagal reflex effects, and Warren (1947) and Colp et al (1948) found that vigorous manipulation of the vagus did not produce bradycardia or cardiac arrest

It is evident that cardiac arrhythmias occasionally follow resection or manipulation of the vagus in the region of the diaphragm, and when they are slight or transient they may remain undetected Accordingly, I decided to investigate the electrocardiographic findings during operative manipulation of the œsophageal and, more particularly, the gastric branches of the vagus This investigation was encouraged by a leading article in THE LANCET (1947) reviewing the possible dangers of tampering with the vagus nerve during vagotomy "The question arises," it reads, " whether handling of the vagus has repercussions on the heart, and it would be interesting to know whether cardiographic studies during dissection of the vagi have been done."

METHODS AND FINDINGS

Using the continuous recording electrocardiograph, it was possible to take tracings before, during, and after any specific operative procedure, and thus to estimate the type and degree of cardiac arrhythmia caused by drugs, anæsthetic agents, and other factors

At first a Cambridge Standard Electrocardiograph was used, but as this machine provides records for only 5 sec. it proved difficult to synchronise the readings with the mani pulation Later a Hellige Portable Electrocardiograph was obtained, and a continuous recording up to 50 feet (6 min.) could then be taken if desired

The three classical limb leads were attached to the patient Copperplate electrodes were made, and the leads were long enough to enable the electrocardiograph to be placed in a far corner of the theatre, away from the operation field. Every effort was made to limit interference from nearby electrical appliances, but at times some interference could not be prevented Between each set of recordings the instrument was standardised by applying a potential of 1 millivolt across the input, which produced a standard beam deflection of 10 mm The actual position of the galvanometer beam could be watched during the operation through an observation window

The electrocardiographic study had to be limited to one limb lead, and on the experience of previous observers, it was decided that lead II was the most satisfactory An attempt was made to obtain control recordings immediately before visceral or vagal manipulation was begun. In cases where the effect of vagal manipulation was under study, traction on the nerve was applied with Spencer Wells forceps or non toothed dissecting forceps

Electrocardiograms were obtained during 36 *operations*, as follow

Partial gastrectomy	17
Laparotomy	4
Ligation of patent ductus arteriosus	3
Œsophagectomy	3
Block dissection of glands in neck	3
Transthoracic gastrectomy	2
Partial gastrectomy and vagotomy	1
Total gastrectomy	1
Gastropexy	1
Heller's operation for achalasia of cardia	1
Thoracotomy	1

The procedures during which electrocardiograms were taken were

Visceral Manipulation	
Traction on stomach	8
Traction on œsophagus	4
Ligation of patent ductus arteriosus	3
Traction on gall bladder	1
Traction on spleen	1
Traction on pelvic colon	1
Paracentesis pericardii	1
Incision of pleura	1
Vagal Manipulation	
Traction on right posterior abdominal vagus	10
Traction on left anterior abdominal vagus	8
Traction on anterior œsophageal vagus	3
Traction on posterior œsophageal vagus	2
Division of anterior and posterior œsophageal vagi	1
Division of left anterior abdominal vagus	1
Division of anterior and posterior abdominal vagi	1
Traction on abdominal vagus above anterior and posterior trunks	1

Electrocardiograms were obtained in the 3 cases of patent ductus arteriosus during the injection of procaine into the left vagus where the nerve crosses the aortic arch In 1 of these (case 13 in accompanying table) the injection caused a transient rise in heart rate from 120 to 143 per minute

In a further 2 cases the effect of traction on the left vagus in the neck was studied during block dissection of malignant lymph glands It is clearly not practical to base any conclusions on two isolated cases, but it may be said that the onset of severe hypotension in one patient (case 24), and of bradycardia in the other

---

* Part of a thesis for the degree of M.D in the University of Cambridge, March, 1950

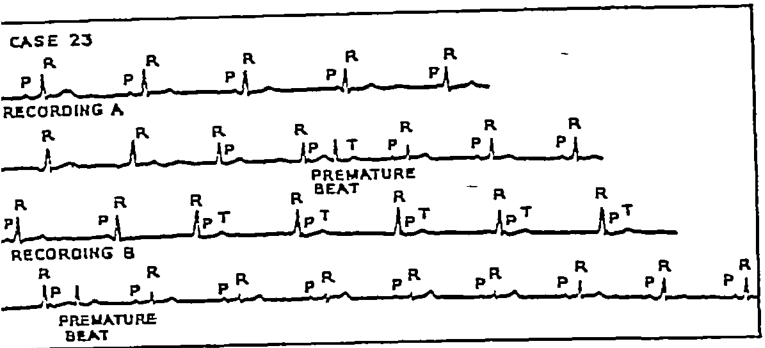

Fig 2 (case 23)—Electrocardiograms (lead II) obtained during transthoracic gastrectomy (A) Continuous recordings before and during traction on the left anterior vagus half an inch below œsophageal opening in the diaphragm. (B) Continuous recording obtained during traction on the nerve and after release of traction.

In all recordings the P waves were upright and normal in appearance, and the P–P intervals were constant (1 36 sec), it is thus apparent that a regular sinus rhythm existed. The R–R intervals excluding those preceding and following the premature beats, were also remarkably constant, and at a faster rate (1 32–1 34 sec) A diminution in amplitude of some of the R waves which followed the premature beats was present The premature beats may have arisen from a focus near the A.V node, as they were almost ' pure " in form.

Conclusion : auriculoventricular dissociation with idioventricular rhythm and premature beats noted in all recordings.

procaine into the vagus sheaths in the neck, abolished the heart block. The observers attributed the arrhythmia to the direct pressure of the diverticulum on the vagus Burstein et al (1949) have reported an A V conduction defect during a transthoracic vagotomy, and this arrhythmia coincided with manipulation of the vagus nerve just above the diaphragm.

In the case under discussion it appears that a summation of effect may have resulted from vagal manipulation during cyclopropane anæsthesia.

Manipulation of the Œsophageal and Gastric Branches of the Vagus Nerve

Experiments on animals have shown that profound disorders of cardiac rate, rhythm, and conduction follow electrical or mechanical stimulation of the cervical and supracardiac portion of the vagus Appreciable changes have rarely followed manipulation of the nerve in the region of the diaphragm

Burstein et al. (1944) made repeated observations in anæsthetised cats and dogs as to the effect of electrical stimulation of the vagus nerves at fixed levels throughout their course They found that the stimulus required to produce a minimal fall in blood pressure when applied to the vagus nerves in the abdomen produced immediate cardiac arrest when applied to the upper thoracic portion of the nerves

Changes in the electrocardiogram on stimulation of the right abdominal vagus nerve in 29 dogs, anæsthetised with cyclopropane, were studied by Martin et al. (1942) Sinus tachycardia with a decrease in the P–R interval, and a diminution in the amplitude of the P and R waves were noted Less frequently, bradycardia, auricular extrasystoles, and auricular flutter occurred

Gullickson et al (1949) have described the findings in dogs during bilateral vagotomy between the pulmonary plexus and the stomach No premedication was given, and endotracheal ether anæsthesia was employed. Bradycardia, changes in amplitude or inversion of the P waves, variations of the P–R intervals, dissociation phenomena, and sino auricular block were noted These electrocardiographic changes were thought to have been specifically related to vagal manipulation but these writers admitted that similar and other, variations also occurred without any definite relation to visceral or vagal stimulation.

Comparable studies in man have seldom been undertaken Martin et al. (1944) have stimulated electrically the right and left cœliac ganglia in patients anæsthetised with cyclopropane or nitrous oxide and ether Bradycardia or other signs of vagal stimulation were seldom seen, in spite of the close proximity of vagal fibres in the region of the cœliac plexus Warren (1947) seems to have been the first to study the electrocardiographic findings during vagotomy In an unspecified number of cases, he found that vigorous manipulation of the nerves failed to alter the recordings. Dennis et al. (1948) also found persistent cardiographic changes no more common after vagotomy than after any other surgical procedure

Since I began my investigation, electrocardiographic findings during transthoracic and transabdominal vagotomy have been published by two independent groups of workers

Burstein et al (1949) found changes in 2 of 9 patients during transthoracic vagal resection. In one case an auriculoventricular conduction defect appeared each time the nerve was manipulated before its division just above the diaphragm In the other case this manœuvre resulted in bradycardia and occasional ventricular extrasystoles These workers believe that these reactions were minimal (1) because procaine was injected into the nerve before its manipulation, and (2) because they were divided as near to the diaphragm as possible

Gullickson et al. (1949) took continuous recordings during bilateral vagotomy (5 transabdominal and 1 transthoracic) Changes apparently related to vagal manipulation and limited to an increase in the P–R interval occurred in 2 cases

I obtained electrocardiograms during manipulation of the œsophageal or gastric branches of the vagus in 22 patients, 29 experiments being conducted The electrocardiographic abnormalities noted after vagal manipulation are of course significant only if absent from the immediate control tracings Thus an isolated ventricular extrasystole in case 21 (see table) may well be due to other causes, such as the anæsthetic Again, the A V dissociation with idioventricular rhythm and premature beats in case 23 (fig 2) evidently bore no specific relation to vagal traction, for it was also present in control recordings As these recordings were obtained immediately before vagal traction, manipulation of the viscera during the transthoracic gastrectomy may have been largely responsible

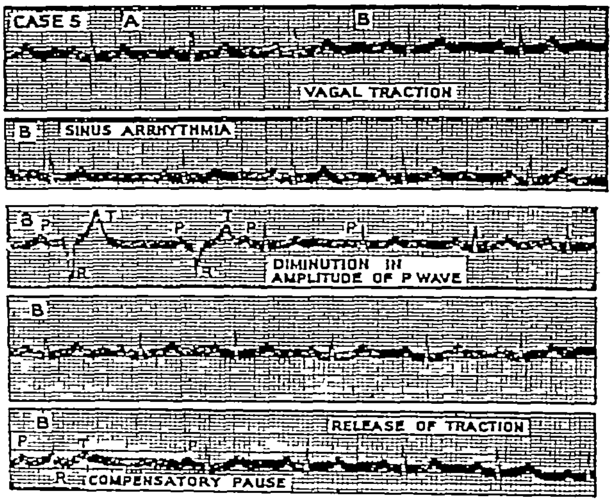

Fig 3 (case 5)—Electrocardiograms (lead II) obtained (A) before vagal manipulation, (B) during traction on the right posterior vagus in the abdomen. Sinus arrhythmia, slight bradycardia, ventricular extrasystoles and diminution in the amplitude of the P waves occurred during vagal manipulation. Control recordings obtained before and after this surgical procedure showed no abnormality

(1938) noted that "traction reflexes" were definitely diminished when regional anæsthesia and inhalation narcosis were used together However, many of these writers have attributed the cardiac irregularities to the anæsthetic agents or to oxygen lack

Manipulation of the Œsophagus

The electrocardiographic findings during manipulation of the œsophagus appear, in the main, to be identical with those described above However, Ressinger has reported auricular flutter occurring when an œsophageal carcinoma was explored, and bradycardia, hypotension, and progressive cyanosis have been noted when traction was applied to an œsophageal diverticulum (Barbour and Tovell 1948)

Of the 4 cases studied in my investigation, 1 showed auriculoventricular dissociation with idioventricular rhythm and premature beats (fig 1)

Case 25 —In a man, aged 68, with an œsophageal carcinoma, thoracotomy was performed under cyclopropane Cardiograms could not be obtained before the induction, but the pulse rate was regular at 80 per min , and the blood pressure was 140/100 The growth extended from $^1/_2$ inch above the diaphragm to the aortic arch, and since it was fixed no attempt was made to resect it During manipulation of the growth, irregularity in the pulse was noted by the anæsthetist, and the first cardiograms were then obtained In an attempt to stop this arrhythmia, intravenous procaine (2 ml of a 1% solution) was administered, but the irregularity persisted The patient died as soon as the wound was closed No appreciable blood-loss occurred during operation At necropsy no coronary disease or valvular heart disease was found The cause of death was not ascertained

In this patient all electrocardiograms taken during operation showed a regular auricular rate of 75 per minute, whilst the ventricular rate was consistently more rapid though less regular (80–100) According to Lewis (1925b) the rate of the escaping ventricles rarely rises above that of the auricles , in such cases the ventricles and auricles beat for the most part independently Yet in this case (and also in case 23) the idioventricular rate was greater than the auricular rate, indicating depression of the sino auricular node

As control recordings before operation were not obtained, the cause of this arrhythmia remains uncertain The necropsy findings suggest that the auriculo ventricular (A V) dissociation was not due to narrowing or occlusion of the larger coronary arteries, or to macroscopic changes in the heart muscle However, persistent heart block of a high grade often occurs in the absence of gross pathological changes Microscopic lesions, such as inflammation, degeneration, or fibrosis affecting the auriculo-ventricular tract may then be found (Lewis 1925a), but in the above case, examination of the junctional tissues was not performed Transient or functional A V block may be due to such diverse causes as asphyxia, uræmia, infectious diseases, or certain drugs (White *1947*), but there is no evidence of these in this case

The arrhythmia recorded during this operation may have been due to the anæsthetic or to the operative procedure, or both It is known that A V dissociation occurs spontaneously during cyclopropane anæsthesia, and it may also follow manipulation of the vagus The surgeon reduced manipulation of the mediastinum to a minimum, but he thinks that the vagus nerves were undoubtedly implicated in the growth, and traction on this may have led to the adverse result described Doublet et al (1948) have demonstrated that the main vagal trunks lie in intimate relationship with the œsophageal musculature , so traction on the œsophagus must cause some disturbance of the vagus

Cyclopropane Anæsthesia —The arrhythmias seen during administration of cyclopropane can often be postponed or aborted by adequate premedication, or by intravenous injection of atropine sulphate (Seevers et al 1934, Meek et al 1937, Rovenstine and Hershenson 1938, Rovenstine and Martin 1941, Allen et al 1942) Some of these writers have suggested that the irregularities are caused by cyclopropane stimulating the parasympathetic, thus producing vagal effects on the heart Further, Adriani et al (1940) have shown that cyclopropane, like acetylcholine, will produce chromodacryorrhœa (red tears) in rats under the effect of eserine These workers conclude that acetylcholine is liberated during cyclopropane anæsthesia, which accords with the conception of cyclopropane as a parasympatheticomimetic agent Moreover, conduction defects, indicated by prolongation of the P–R interval and other severe forms of A V block, do not occur in dogs during cyclopropane anæsthesia if the cardiac vagus nerves have previously been divided (Robbins and Baxter 1937) , so vagal stimulation may be expected to increase the incidence of conduction defects

Vagal Manipulation —Auriculoventricular dissociation has been noted in animals after electrical or mechanical stimulation of the cervical and supracardiac portion of the vagus (Einthoven 1908, Cohn 1912, Robinson 1913, Cohn and Lewis 1913, Lewis 1914, Mautner and Luisada 1941) Various anæsthetics were employed, and it may be argued that the abnormalities were due to the action of these agents on the heart or medullary centres, rather than due to actual mechanical stimulation of the vagus nerve However, Iglaver et al (1941) showed that the electrocardiograms obtained when stimulating the parasympathetic nervous system by chemical methods (intravenous mecholyl) in unanæsthetised dogs were almost identical with the recordings produced by the earlier investigators during electrical stimulation of the vagus in the neck in anæsthetised animals

In man, A.V dissociation has followed mechanical manipulation of the carotid sinus in unanæsthetised subjects (Robinson and Draper 1912, Wilson and Arbor 1915, *Ferris et al* 1935) Weiss et al *(1934)* have described a case in which cardiographic evidence of complete A V dissocation followed distension of a traction diverticulum of the œsophagus Release of pressure in the diverticulum brought a return to normal sinus rhythm, and the administration of atropine, or the infiltration of

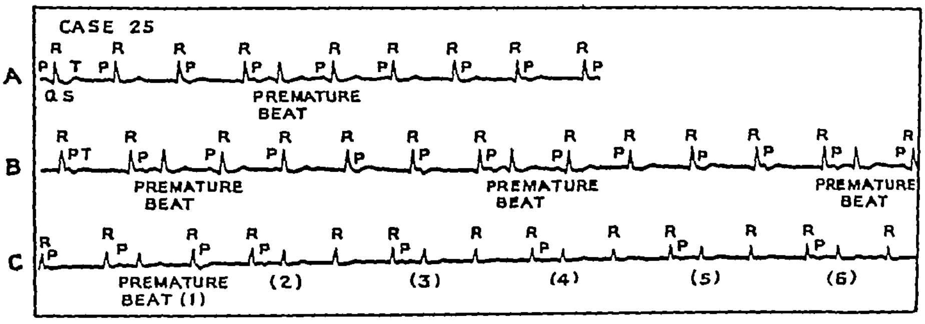

Fig 1 (case 25)—Electrocardiograms (lead II) obtained : (A) during slight traction on an œsophageal carcinoma (B) 5 minutes later after administration of intravenous procaine ; and (C) 8 minutes after B, and 10 minutes before death

The P waves were upright and normal in appearance , the auricular rate was regular at 75 per min. In A and B premature beats occurred every 6th beat , in C they occurred every 3rd beat In B, the typical sequence of the R–R intervals was *0 36*, 0 66, 0 70, 0 70, 0 74, 0 76, *0 36* sec , in C the sequence was *0 36*, 0 60, 0 66, *0 36* sec The idioventricular rate was quicker than the auricular rate in all recordings, the maximal rate being found in C The ventricular pacemaker may be near, or just below, the A V node, since all complexes, including the premature ones, appear normal

Conclusion : auriculoventricular dissociation with a fast idioventricular rhythm and premature beats noted in all recordings

CYANOSIS IN INFANCY FROM NITRATES IN DRINKING-WATER

MARY C EWING
M.B Edin
HOUSE PHYSICIAN, WEST SUFFOLK GENERAL HOSPITAL

R M MAYON-WHITE
M.D, Ph D Lond, M R C P, D C.H
CONSULTING PÆDIATRICIAN, IPSWICH AREA

METHÆMOGLOBINÆMIA as a cause of cyanosis in infancy has lately received a considerable amount of attention (see *Lancet* 1948) It is now recognised that a frequent cause is nitrate contamination of water used in making up artificial feeds for a baby In the bowel the nitrate is converted to nitrite, which, when absorbed, oxidises hæmoglobin to methæmoglobin The contaminated water has usually come from a shallow well Boiling such water is no safeguard Most of the cases reported have occurred in the country districts of the central States of the U S.A, where the syndrome is common and farmers speak of the cases as "blue water babies" (Donahoe 1949)

No cases have hitherto been published in the British Isles, but during the summer of 1950 2 cases have come to our notice in the Suffolk countryside

CASE RECORDS

Case 1 —A boy was born in hospital and discharged to his home in a village near Ipswich on the tenth day of life, April 23, 1950 Though breast feeding was not fully established at the time of discharge, the child was regarded as healthy At home full artificial feeding with a powdered milk was introduced and for a fortnight good progress was made At the age of 4 weeks the child s general health deteriorated, there were diarrhœa and vomiting, and the child s complexion was slate blue Feeding was stopped, and boiled water was substituted Next day the child was deeply cyanosed and very weak, and died in an ambulance on the way to the East Suffolk and Ipswich Hospital

Necropsy (Dr Trevor Shaw) —Apart from slight inhalation pneumonia no obvious cause of death was found in particular the cardiovascular system was normal Brown discoloration of all the solid viscera was noted, and spectroscopy of the blood showed methæmoglobin in high concentration. There was no evidence of hæmolysis No medicines had been given.

One of us (R M. M W) was consulted about other possible causes of methæmoglobinæmia in a child of this age The suggestion that the drinking water be examined for nitrates was followed up and proved fruitful. Water for the infant's milk mixture had been obtained from a shallow well and had been boiled before use Specimens of this water were found to be heavily polluted and unfit for drinking, in particular, nitrates were present at a concentration of 200 parts per million. A trace of nitrite was also present

The death of this infant was considered to be due to methæmoglobinæmia from the absorption of nitrites produced by the action of intestinal organisms on the nitrates in the water used to make up the milk mixture

Case 2 —A boy, aged 6 weeks, was admitted to the West Suffolk General Hospital, Bury St Edmunds on the evening of July 31, 1950, with deep cyanosis His mother had first noticed a bluish colour of his skin on the morning of the previous day Until then he had been healthy, feeding well and gaining weight He had vomited once, on the evening of admission. His mother stated that the blue colour had not changed since first seen, and was not altered by the effort of feeding or by crying The patient was the fifth child in the family, a normal delivery at term There was no history of cyanosis at birth or of subsequent "blue attacks" Breast feeding had been abandoned at ten days, thereafter he had been fed on a proprietary dried milk

On admission he was weak, limp, and intensely cyanosed Respirations were shallow, and the rate increased, but there were no abnormal physical signs in the heart or lungs There was no improvement of his colour or of his general condition after half an hour in an oxygen box Methæmoglobinæmia was suspected Blood drawn from a vein was deep chocolate-brown, spectroscopy confirmed the presence of methæmoglobin in considerable concentration. There was no evidence of intravascular hæmolysis

Treatment —An exchange transfusion was given. The catheter was introduced through a cut-down incision over the saphenous opening (Arnold and Alford 1948) A recent bottle of compatible blood from the hospital bank was prepared as a partly concentrated cell suspension by pouring off the supernatant plasma The exchange was given in 10 ml stages, and successive samples of the blood returned from the infant were analysed (see table) The volumes of the exchange were adjusted to leave a "credit balance" in favour of the infant to correct a pre existing anæmia (350 ml given, 270 ml withdrawn)

Progress —During the transfusion the child's condition steadily improved, the cyanosis giving place to a pink complexion. The colour of blood withdrawn from the baby became progressively less brown and more nearly that of normal venous blood By the end of the transfusion the infant was crying lustily He was offered and took a full feed, thereafter he behaved like a normal healthy child. The wound healed by first intention Though fit to be discharged, the boy was kept in hospital till the tenth day after admission, when we had a satisfactory report on his home water supply

METHÆMOGLOBIN LEVELS (CASE 2)

When estimated	(1) Total methæmoglobin (g per 100 ml)	(2) Total hæmoglobin (g per 100 ml)	(1) as percentage of (2)
Before transfusion (2 hours after admission)	4	9	45%
During exchange			
After 100 ml withdrawn	3	10	30%
After 200 ml.	2	12	15%
After 250 ml	<1·5	12	<15%
After transfusion (270 ml withdrawn)	<1·5	12	<15%

The method used for estimating methæmoglobin was an adaptation of the method for carboxyhæmoglobin described by Harrison (1947) The samples for estimating methæmoglobin were compared in a Hartridge reversion spectroscope against serial dilutions of the same blood in which all the hæmoglobin had been converted to methæmoglobin by the addition of a crystal of potassium ferricyanide Total hæmoglobin was estimated by the Sahli acid hæmatin method

The methæmoglobin figures are approximate and illustrative only The quantitative analysis could not be made until three days after collection. It was determined that, under the conditions of storage, the methæmoglobin content of all samples diminished so quickly that no sample contained a detectable amount ten days after collection The figures in column (1) above, are therefore likely to be an underestimate of the actual concentration of methæmoglobin present

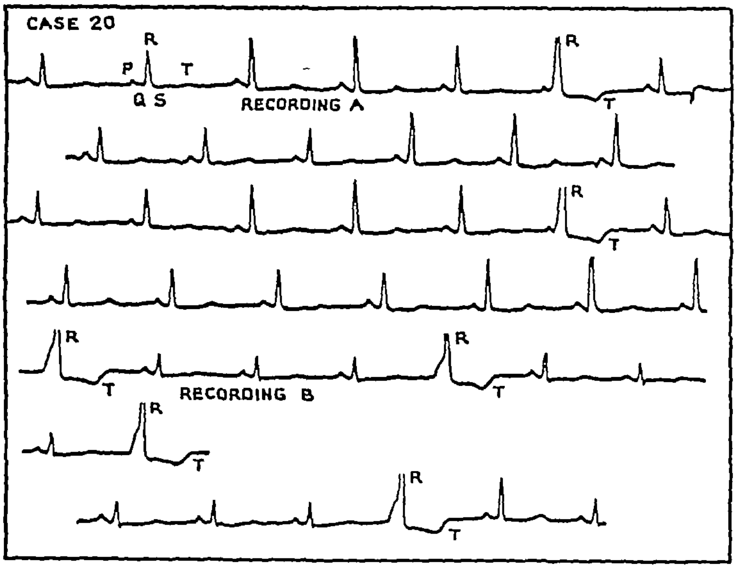

Fig 4 (case 20)—Electrocardiograms (lead II) obtained during œsophagectomy (A) Occasional ventricular extrasystoles present in continuous recordings 1–4. (B) One minute later, after division of the anterior and posterior trunks of the vagus over the lower third of the œsophagus, ventricular extrasystoles appeared regularly every 4th beat (continuous recordings 5–7)

for the cardiographic changes, but more probably these were due to cyclopropane anæsthesia

However, in 3 cases vagal manipulation seems to have been a definite factor in the production of a temporary cardiovascular disturbance Traction on the right posterior vagus nerve in the abdomen was associated with hypotension in case 26, and with bradycardia, ventricular extrasystoles, and diminution in the amplitude of the P waves in case 5 (fig 3) In case 20, control electro cardiograms during an œsophagectomy showed isolated ventricular extrasystoles, but after manipulation and subsequent division of the anterior and posterior trunks of the vagus nerve, over the lower third of the œsophagus, they appeared regularly every 4th beat (fig 4) In this case preliminary injection of procaine into the vagus failed to prevent the arrhythmia All 3 patients had had adequate premedication with morphine and atropine, or their derivatives

Manipulation or resection of the œsophageal or gastric branches of the vagus produced hypotension or definite electrocardiographic changes in 3 of the 13 patients receiving cyclopropane Auriculoventricular dissociation with idioventricular rhythm and premature beats was noted in 2 others (cases 23 and 25) during operation under cyclopropane Electrocardiographic changes did not follow vagal manipulation in the 9 cases where cyclo propane was not used (including 5 in which a regional block with local anæsthesia was given)

SUMMARY AND CONCLUSIONS

Profound disorders of heart rate, rhythm, and conduction may follow stimulation or division of the vagus nerve in its cervical or supracardiac course Significant changes rarely follow manipulation or resection of the nerve in the region of the diaphragm

Although cardiac arrhythmias have seldom been recognised clinically during vagotomy, it was thought probable that minor and transient irregularities might have remained undetected Accordingly, electrocardiograms were obtained during operative manipulation of the œsophageal and gastric branches of the vagus

Hypotension or significant electrocardiographic changes were noted in 3 of 13 patients in whom the œsophageal or gastric branches of the vagus were manipulated or divided under cyclopropane anæsthesia Auriculoventricular dissociation with idioventricular rhythm and premature beats was observed in 2 further patients under cyclopropane These 5 cases had had premedication with morphine and atropine or their derivatives Electrocardiographic changes did not follow vagal manipulation in the 9 cases where cyclopropane was not used

Cyclopropane stimulates the parasympathetic, and a summation of effects might be expected from vagal manipulation during cyclopropane anæsthesia The findings of this limited investigation suggest that when cyclopropane is used, manipulation of the œsophageal and gastric branches of the vagus should be avoided as much as possible

This work could not have been undertaken without the full coöperation of the surgical teams at Bristol Royal Infirmary I am especially grateful to Mr D C Bodenham, Mr T J Butler, Mr W M Capper, Mr H J Croot, and Prof R. Milnes Walker, for permission to investigate cases during operation, and for assistance readily given. I would like further to express my thanks to Prof C Bruce Perry for his encouragement and criticism, to Dr J H Challenger for the loan of the electrocardiograph, to Dr J A. Cosh for his help in the interpretation of the electrocardiograms, and to Dr F G Bolton for his constant interest and advice

Mr A H. Williams of the department of medicine, Cardiff Royal Infirmary, and Mr F A. Godman of the department of photography, University of Bristol, kindly photographed the continuous electrocardiographic recordings.

Continued at foot of next column

paid to its efficacy and speed of action On clinical grounds treatment was thought to be urgently necessary in our case 2 Exchange blood transfusion was used because we preferred the use of a familiar technique which offered logical treatment to experimenting on a critically ill child with a drug with which neither of us was familiar and which one of us knew to have been the subject of controversy in the treatment of the somewhat similar condition of carboxyhæmoglobinæmia We dismissed methylene-blue too lightly The experiments of Wendel (1939) and Hartmann et al. (1938) have since come to our notice Wendel showed that in high concentration methylene blue oxydised hæmoglobin to methæmoglobin, but in lower concentration (1 or 2 mg per kg of body weight) rapidly reduced methæmoglobin to hæmoglobin Many of the abovementioned reports of well water cyanosis mention disappearance of cyanosis within 30–60 minutes of the intravenous injection of methylene blue

Ascorbic acid is of value (Deeny et al 1943) in the treatment of chronic idiopathic methæmoglobinæmia but seems too slow in its action to have a place in the therapy of the condition under discussion here

Though treatment with methylene blue is rapidly effective, the child should not be discharged until a safe supply of water has been assured at its home Relapses are not unknown Ferrant (1946) reported 2 cases from Louvain in Belgium, the second child was readmitted, again with intense methæmoglobinæmia, five days after discharge from hospital and died before treatment could be given

DISCUSSION

So far as we know, no cases of well water cyanosis have been reported in adults, but in view of the hereditary nature of achlorhydria one wonders if a similar mechanism may not operate in some cases of "familial idiopathic methæmoglobinæmia" Most of the few cases reported seem to have been investigated in hospital, and the home background is usually not described Some of the patients have continued cyanosed in hospital and therefore seem unlikely to belong to the syndrome under discussion here The largest group of patients studied in one family "lived on a farm in a remote and mountainous part of Ireland", they refused admission to hospital and were investigated in their own home (Gibson and Harrison 1947)

In the past nitrates and nitrites have been considered harmless in themselves, but they are held to be an important indication that the water is contaminated with sewage Ammonia and other nitrogenous compounds of manure are oxidised to nitrates by soil bacteria Thus the presence of nitrates or nitrites in a sample of drinking water suggests contamination by organic matter Theoretically it is possible for coliform organisms to be held back by the soil as water percolates through it, yet for nitrates in solution to pass into a well, in practice this rarely seems to happen coliform organisms being usually demonstrable in well waters containing nitrates

All the cases of "well water cyanosis" of which we have read have been in artificially fed young infants living in country districts, the water supply in each case has been a shallow well Surface and subsurface contamination of shallow wells is notoriously easy, particularly in summers like that of 1950 in England, when a heavy rainfall followed twelve months' exceptional drought Probably most of the shallow wells used for drinking in this country are in private ownership This is important from a public health point of view, for the local authority has powers to test such a supply only after receipt of a specific complaint about the water To the general public the greater palatability of cold water from a well makes it more acceptable in summer than lukewarm water from the above ground storage tanks of many village supplies

Popular belief that boiling the water makes it safe is misplaced in the case of nitrate contamination, for the nitrate concentration remains unchanged Case 1 illustrates another facet of the danger When the child first became ill with diarrhœa and vomiting, a neighbour recommended that feeding should be stopped temporarily and boiled water substituted This advice, though generally unexceptionable in gastro enteritis, can only make matters worse in methæmoglobinæmia of the type under discussion here

From our experience of these two cases and from our study of accounts of similar cases we endorse the recommendation given by Taylor (1949) that nitrates should be regarded as a potentially dangerous contaminant of drinking water, and that 20 parts per million should be regarded as the highest acceptable figure in water used for preparing an infant's milk mixture Some such standard figure seems desirable, if only as a guide, for the report of clinical cases of a public health hazard is likely to be followed by requests for analysis of samples from suspected sources Thus, since "blue water babies" have become recognised, surveys of water supplies have been carried out in the Middle West of America (Johnson et al 1946, Weart 1948) In one county in Illinois more than 25% of waters from rural wells contained more than 100 parts per million of nitrate nitrogen (Weart 1948) Such a state of affairs constitutes a real threat to the infant population of the neighbourhood

SUMMARY

Two cases are reported of cyanosis from methæmoglobinæmia in infancy Both children were reared in Suffolk villages, both were artificially fed, and in each case the water used to prepare the milk mixture was obtained from a shallow well In each case the well water was contaminated with coliform organisms and nitrates One child died before admission to hospital, but the other was treated by exchange blood transfusion and recovered

The cases are reported because they are believed to be the first examples in Great Britain of a syndrome which has recently become widely recognised in country districts of North America and the Netherlands The literature is briefly reviewed It seems to be acceptably established that young infants may have coliform organisms in the upper part of the intestinal tract, in such infants nitrates contaminating the drinking water may, on ingestion, be reduced by the organism to nitrites sufficiently high in the small intestine for the nitrites to be absorbed and methæmoglobinæmia to be produced

If suspected the condition is easily diagnosed The recognised treatment is the intravenous injection of methylene blue 1 or 2 mg per kg of body weight

The danger of nitrates in water fed to babies merits wider recognition Boiling such water does not render it safe It has been authoritatively recommended that 20 parts per million of nitrates should be regarded as the highest acceptable figure in water used for preparing an infant's milk mixture We endorse that recommendation

We are indebted to Dr Trevor Shaw and to Mr C T Dawson, Ipswich Borough Coroner, for permission to cite details of case 1, to Dr R H Clayton, M O H, Bury St Edmunds, for investigating the water supply in case 2, to Dr Eric Wood and Dr S Greenburgh, public analysts of Norwich and of Cambridge, for their reports on the water supplies of cases 1 and 2 respectively Dr Wood has given us much information on matters that lie in his field rather than ours Mr S T Ryder, F I M L T, estimated the methæmoglobin in case 2

Since this paper was written, a third case, from another part of Suffolk, has been admitted under *one of us* This

Follow up —The child has been seen in the follow up clinic since discharge , he is healthy, without cyanosis, and without detectable methæmoglobinæmia

The suspicion that this was a case of " well water cyanosis " was entertained but could not be confirmed until after the transfusion treatment was completed Next day the mother was questioned She explained that the baby's feeds were made up by boiling water obtained by a bucket from a shallow well in the yard of a public house opposite her cottage Analysis of this water showed it to be " heavily contaminated with coliform organisms " (probable number of *Bact coli* in excess of 180 per 100 ml) and to contain 95 parts per million of nitrates Nitrites were absent The source was a simple dug well 42 ft deep containing 20 ft of water at the time of analysis Also available to this group of cottages (but not used by most of the inhabitants for drinking) was water from a deep bore supply to a storage tank. This water (considered unfit for drinking by the analyst as a result of his findings) did not contain nitrates though contaminated, but to a less degree, with coliform organisms

HISTORICAL REVIEW

Though enterogenous cyanosis holds its place in the classification of causes of cyanosis, methæmoglobinæmia sufficient to discolour the skin seems to be rare nowadays in intestinal disorders Henstall and Dameshek (1936) reported 1 case and collected 36 others previously published The early sulphonamide preparations provided a new example of cyanosis of this type Bismuth subnitrate, formerly used in the treatment of infantile gastro enteritis, has been given up because of this danger (Roe 1933)

Methæmoglobinæmia may follow the absorption of many chemicals besides sulphonamides and bismuth subnitrate, such as aniline and its derivatives acetanilid and phenacetin, nitrophenol, potassium chlorate, and various nitrites Occasional cases of methæmoglobinæmia in infants have been reported in which none of these chemicals was incriminated Such cases have been described as " idiopathic " methæmoglobinæmia (Schwartz and Rector 1940, Stahr 1941) Comly (1947) reported two such cases, but he recognised that nitrates contaminating the well-water used to make up the feeds were the cause of his two cases and suspected the same ætiology in several other cyanosed infants whose colour improved as soon as the water supply was changed Diarrhœa was a feature of Comly's cases , the conversion of ingested nitrates to nitrites he attributed to organisms present in the bowel during gastro intestinal disturbances He recognised that nitrites, but not nitrates, oxidised hæmoglobin to methæmoglobin Only young babies seemed to be affected Comly thought that the immunity of adults and older children drinking the same water was due to the relatively greater water intake in infancy

Cornblath and Hartmann (1948) investigated the mechanism of the enteric nitrate nitrite conversion by a series of in-vivo experiments on infants They emphasise the point that " well-water cyanosis " is limited to the first few weeks of life, when physiological gastric hypochlorhydria is greatest They showed that in such infants lower bowel organisms (*Bact ærogenes*, *Bact freundii*, and *Bact coli*) which have the property of reducing nitrates to nitrites are to be found in the upper intestine and may be grown even from saliva and stomach washings They found that the growth of these organisms was inhibited at a pH of 4 or less They showed that oral ingestion of water containing nitrate would only produce methæmoglobinæmia in infants who had a gastric juice of pH greater than 4 and nitrate reducing bacteria in the upper gastro intestinal tract Cornblath and Hartmann assume that, where gastric acidity inhibited the growth of colon organisms in the upper intestine, any ingested nitrate is absorbed harmlessly before conversion to nitrite can take place A baby aged 3 months with a transverse colostomy gave them the opportunity to demonstrate the point nicely In this child 200 mg of nitrate ion fed by mouth produced cyanosis and converted 25% of the hæmoglobin to methæmoglobin , 600 mg of nitrate ion injected into the colostomy for two days did not cause cyanosis and converted only 4% of the hæmoglobin to methæmoglobin

Methæmoglobin is a true oxide of hæmoglobin, the iron of the molecule being oxidised to the ferric form , it is only slowly broken down in the body and is too stable to be of use to the body for transport of oxygen The cellular anoxia caused by methæmoglobinæmia depends on this, but another factor operates in the same direction Like carboxyhæmoglobin, methæmoglobin shifts to the left the oxygen dissociation curve of a specimen of blood containing it (Darling and Roughton 1942) Thus, blood containing a proportion of methæmoglobin not only has its oxygen carrying power reduced by that amount but also such oxygen as is carried by the remaining hæmoglobin is less readily ceded to the tissues.

DIAGNOSIS

The diagnosis is not difficult The onset of cyanosis in a bottle fed baby should lead to suspicion of this condition if no gross abnormality can be found on examination of the cardiovascular and respiratory systems The suspicion warrants examination of the blood A specimen of venous blood containing an appreciable quantity of methæmoglobin is chocolate brown, clearly recognisable as abnormal to the naked eye by daylight or electric light , the presence of methæmoglobin is readily confirmed spectroscopically If methæmoglobin is found, inquiry should be made about recent medicines and the water supply If the water supply is suspected, the case should be notified to the Medical Officer of Health with a request for an analysis of the drinking water In all cases to date the nitrate polluted water has been drawn from a shallow well on a farm or in a small country village

Diarrhœa and vomiting are not essential features of the syndrome, but vomiting, presumably often from cerebral anoxia, is usual Inhalation pneumonia may complicate the condition Methæmoglobin is so easily detected that, if doubt exists, its presence should be excluded before it is assumed that the cyanosis is due to pneumonia

On a priori grounds it seems that the more water that is used in preparing the feeds the more likely is methæmoglobinæmia to be produced Thus, if the water supply is contaminated by nitrates, methæmoglobinæmia is most likely in those infants fed on mixtures made up from powdered milk (because the greatest amount of water is used), evaporated milk would occupy an intermediate position, and modified cow's milk mixtures should be the safest of artificial foods Donahoe (1949) suggests that both cows and women when drinking nitrate contaminated water may secrete the nitrate ion in their milk

TREATMENT

The history of our two cases illustrates the fact that nitrate methæmoglobinæmia is a cumulative poisoning, taking some days or a week or two to develop Once the ingestion of nitrates has been stopped, the disease is self limiting The necessary change to purer water can most easily be made by admitting the infant to hospital On admission many such infants are critically ill, and urgent treatment is called for because of the danger of continued tissue anoxia Oxygen cannot reduce the amount of methæmoglobin , the hæmoglobin may be presumed to be almost completely oxygenated Therefore the administration of oxygen should be regarded as no more than a temporary expedient while preparations are being made for specific therapy

The intravenous injection of methylene blue in doses of 1 or 2 mg per kg of body weight is the treatment of choice In the American published reports tribute is paid to its efficacy and speed of action On clinical grounds treatment was thought to be urgently necessary in our case 2 Exchange blood transfusion was used because we preferred the use of a familiar technique which offered logical treatment to experimenting on a critically ill child with a drug with which neither of us was familiar and which one of us knew to have been the subject of controversy in the treatment of the somewhat similar condition of carboxyhæmoglobinæmia We dismissed methylene blue too lightly The experiments of Wendel (1939) and Hartmann et al (1938) have since come to our notice Wendel showed that in high concentration methylene blue oxydised hæmoglobin to methæmoglobin, but in lower concentration (1 or 2 mg per kg of body-weight) rapidly reduced methæmoglobin to hæmoglobin Many of the above mentioned reports of well water cyanosis mention disappearance of cyanosis within 30–60 minutes of the intravenous injection of methylene blue

Ascorbic acid is of value (Deeny et al 1943) in the treatment of chronic idiopathic methæmoglobinæmia but seems too slow in its action to have a place in the therapy of the condition under discussion here

Though treatment with methylene blue is rapidly effective, the child should not be discharged until a safe supply of water has been assured at its home Relapses are not unknown Ferrant (1946) reported 2 cases from Louvain in Belgium, the second child was readmitted, again with intense methæmoglobinæmia, five days after discharge from hospital and died before treatment could be given

DISCUSSION

So far as we know, no cases of well water cyanosis have been reported in adults, but in view of the hereditary nature of achlorhydria one wonders if a similar mechanism may not operate in some cases of "familial idiopathic methæmoglobinæmia" Most of the few cases reported seem to have been investigated in hospital, and the home background is usually not described Some of the patients have continued cyanosed in hospital and therefore seem unlikely to belong to the syndrome under discussion here The largest group of patients studied in one family "lived on a farm in a remote and mountainous part of Ireland", they refused admission to hospital and were investigated in their own home (Gibson and Harrison 1947)

In the past nitrates and nitrites have been considered harmless in themselves, but they are held to be an important indication that the water is contaminated with sewage Ammonia and other nitrogenous compounds of manure are oxidised to nitrates by soil bacteria Thus the presence of nitrates or nitrites in a sample of drinking-water suggests contamination by organic matter Theoretically it is possible for coliform organisms to be held back by the soil as water percolates through it, yet for nitrates in solution to pass into a well, in practice this rarely seems to happen coliform organisms being usually demonstrable in well waters containing nitrates

All the cases of "well water cyanosis" of which we have read have been in artificially fed young infants living in country districts, the water supply in each case has been a shallow well. Surface and subsurface contamination of shallow wells is notoriously easy, particularly in summers like that of 1950 in England, when a heavy rainfall followed twelve months' exceptional drought Probably most of the shallow wells used for drinking in this country are in private ownership This is important from a public health point of view, for the local authority has powers to test such a supply only after receipt of a specific complaint about the water To the general public the greater palatability of cold water from a well makes it more acceptable in summer than lukewarm water from the above ground storage tanks of many village supplies

Popular belief that boiling the water makes it safe is misplaced in the case of nitrate contamination, for the nitrate concentration remains unchanged Case 1 illustrates another facet of the danger When the child first became ill with diarrhœa and vomiting, a neighbour recommended that feeding should be stopped temporarily and boiled water substituted This advice, though generally unexceptionable in gastro enteritis, can only make matters worse in methæmoglobinæmia of the type under discussion here

From our experience of these two cases and from our study of accounts of similar cases we endorse the recommendation given by Taylor (1949) that nitrates should be regarded as a potentially dangerous contaminant of drinking water, and that 20 parts per million should be regarded as the highest acceptable figure in water used for preparing an infant's milk mixture Some such standard figure seems desirable, if only as a guide, for the report of clinical cases of a public health hazard is likely to be followed by requests for analysis of samples from suspected sources Thus, since "blue water babies" have become recognised, surveys of water supplies have been carried out in the Middle West of America (Johnson et al 1946, Weart 1948) In one county in Illinois more than 25% of waters from rural wells contained more than 100 parts per million of nitrate nitrogen (Weart 1948) Such a state of affairs constitutes a real threat to the infant population of the neighbourhood

SUMMARY

Two cases are reported of cyanosis from methæmoglobinæmia in infancy Both children were reared in Suffolk villages, both were artificially fed, and in each case the water used to prepare the milk mixture was obtained from a shallow well In each case the well water was contaminated with coliform organisms and nitrates One child died before admission to hospital, but the other was treated by exchange blood transfusion and recovered

The cases are reported because they are believed to be the first examples in Great Britain of a syndrome which has recently become widely recognised in country districts of North America and the Netherlands The literature is briefly reviewed It seems to be acceptably established that young infants may have coliform organisms in the upper part of the intestinal tract, in such infants nitrates contaminating the drinking water may, on ingestion, be reduced by the organism to nitrites sufficiently high in the small intestine for the nitrites to be absorbed and methæmoglobinæmia to be produced

If suspected the condition is easily diagnosed The recognised treatment is the intravenous injection of methylene blue 1 or 2 mg *per kg of body weight*

The danger of nitrates in water fed to babies merits wider recognition Boiling such water does not render it safe It has been authoritatively recommended that 20 parts per million of nitrates should be regarded as the highest acceptable figure in water used for preparing an infant's milk mixture We endorse that recommendation

We are indebted to Dr Trevor Shaw and to Mr C T Dawson, Ipswich Borough Coroner, for permission to cite details of case 1, to Dr R H. Clayton, M.O.H, Bury St Edmunds, for investigating the water supply in case 2, to Dr Eric Wood and Dr S Greenburgh, public analysts of Norwich and of Cambridge, for their reports on the water supplies of cases 1 and 2 respectively Dr Wood has given us much information on matters that lie in his field rather than ours Mr S T Ryder, F.I.M.L.T, estimated the methæmoglobin in case 2

Since this paper was written, a third case, from another part of Suffolk, has been admitted under one of us This

Follow up—The child has been seen in the follow up clinic since discharge, he is healthy, without cyanosis, and without detectable methæmoglobinæmia

The suspicion that this was a case of "well water cyanosis" was entertained but could not be confirmed until after the transfusion treatment was completed Next day the mother was questioned She explained that the baby's feeds were made up by boiling water obtained by a bucket from a shallow well in the yard of a public house opposite her cottage Analysis of this water showed it to be "heavily contaminated with coliform organisms" (probable number of *Bact coli* in excess of 180 per 100 ml) and to contain 95 parts per million of nitrates Nitrites were absent The source was a simple dug well 42 ft deep containing 20 ft of water at the time of analysis Also available to this group of cottages (but not used by most of the inhabitants for drinking) was water from a deep bore supply to a storage tank. This water (considered unfit for drinking by the analyst as a result of his findings) did not contain nitrates though contaminated, but to a less degree, with coliform organisms

HISTORICAL REVIEW

Though enterogenous cyanosis holds its place in the classification of causes of cyanosis, methæmoglobinæmia sufficient to discolour the skin seems to be rare nowadays in intestinal disorders Henstall and Dameshek (1936) reported 1 case and collected 36 others previously published The early sulphonamide preparations provided a new example of cyanosis of this type Bismuth subnitrate, formerly used in the treatment of infantile gastro enteritis, has been given up because of this danger (Roe 1933)

Methæmoglobinæmia may follow the absorption of many chemicals besides sulphonamides and bismuth subnitrate, such as aniline and its derivatives acetanilid and phenacetin, nitrophenol, potassium chlorate, and various nitrites Occasional cases of methæmoglobinæmia in infants have been reported in which none of these chemicals was incriminated Such cases have been described as "idiopathic" methæmoglobinæmia (Schwartz and Rector 1940, Stahr 1941) Comly (1947) reported two such cases, but he recognised that nitrates contaminating the well-water used to make up the feeds were the cause of his two cases and suspected the same ætiology in several other cyanosed infants whose colour improved as soon as the water supply was changed Diarrhœa was a feature of Comly's cases, the conversion of ingested nitrates to nitrites he attributed to organisms present in the bowel during gastro intestinal disturbances He recognised that nitrites, but not nitrates, oxidised hæmoglobin to methæmoglobin Only young babies seemed to be affected Comly thought that the immunity of adults and older children drinking the same water was due to the relatively greater water intake in infancy

Cornblath and Hartmann (1948) investigated the mechanism of the enteric nitrate nitrite conversion by a series of in vivo experiments on infants They emphasise the point that "well water cyanosis" is limited to the first few weeks of life, when physiological gastric hypochlorhydria is greatest They showed that in such infants lower bowel organisms (*Bact ærogenes*, *Bact freundii*, and *Bact coli*) which have the property of reducing nitrates to nitrites are to be found in the upper intestine and may be grown even from saliva and stomach washings They found that the growth of these organisms was inhibited at a pH of 4 or less They showed that oral ingestion of water containing nitrate would only produce methæmoglobinæmia in infants who had a gastric juice of pH greater than 4 and nitrate reducing bacteria in the upper gastro intestinal tract Cornblath and Hartmann assume that, where gastric acidity inhibited the growth of colon organisms in the upper intestine, any ingested nitrate is absorbed harmlessly before conversion to nitrite can take place A baby aged 3 months with a transverse colostomy gave them the opportunity to demonstrate the point nicely In this child 200 mg of nitrate ion fed by mouth produced cyanosis and converted 25% of the hæmoglobin to methæmoglobin, 600 mg of nitrate ion injected into the colostomy for two days did not cause cyanosis and converted only 4% of the hæmoglobin to methæmoglobin

Methæmoglobin is a true oxide of hæmoglobin, the iron of the molecule being oxidised to the ferric form, it is only slowly broken down in the body and is too stable to be of use to the body for transport of oxygen. The cellular anoxia caused by methæmoglobinæmia depends on this, but another factor operates in the same direction Like carboxyhæmoglobin, methæmoglobin shifts to the left the oxygen dissociation curve of a specimen of blood containing it (Darling and Roughton 1942) Thus, blood containing a proportion of methæmoglobin not only has its oxygen carrying power reduced by that amount but also such oxygen as is carried by the remaining hæmoglobin is less readily ceded to the tissues.

DIAGNOSIS

The diagnosis is not difficult The onset of cyanosis in a bottle fed baby should lead to suspicion of this condition if no gross abnormality can be found on examination of the cardiovascular and respiratory systems The suspicion warrants examination of the blood A specimen of venous blood containing an appreciable quantity of methæmoglobin is chocolate brown, clearly recognisable as abnormal to the naked eye by daylight or electric light, the presence of methæmoglobin is readily confirmed spectroscopically If methæmoglobin is found, inquiry should be made about recent medicines and the water supply If the water supply is suspected, the case should be notified to the Medical Officer of Health with a request for an analysis of the drinking water In all cases to date the nitrate polluted water has been drawn from a shallow well on a farm or in a small country village

Diarrhœa and vomiting are not essential features of the syndrome, but vomiting, presumably often from cerebral anoxia, is usual Inhalation pneumonia may complicate the condition Methæmoglobin is so easily detected that, if doubt exists, its presence should be excluded before it is assumed that the cyanosis is due to pneumonia

On a priori grounds it seems that the more water that is used in preparing the feeds the more likely is methæmoglobinæmia to be produced Thus, if the water supply is contaminated by nitrates, methæmoglobinæmia is most likely in those infants fed on mixtures made up from powdered milk (because the greatest amount of water is used), evaporated milk would occupy an intermediate position, and modified cow's milk mixtures should be the safest of artificial foods Donahoe (1949) suggests that both cows and women when drinking nitrate contaminated water may secrete the nitrate ion in their milk

TREATMENT

The history of our two cases illustrates the fact that nitrate methæmoglobinæmia is a cumulative poisoning, taking some days or a week or two to develop Once the ingestion of nitrates has been stopped, the disease is self limiting The necessary change to purer water can most easily be made by admitting the infant to hospital. On admission many such infants are critically ill, and urgent treatment is called for because of the danger of continued tissue anoxia Oxygen cannot reduce the amount of methæmoglobin, the hæmoglobin may be presumed to be almost completely oxygenated Therefore the administration of oxygen should be regarded as no more than a temporary expedient while preparations are being made for specific therapy

The intravenous injection of methylene blue in doses of 1 or 2 mg per kg of body weight is the treatment of choice In the American published reports tribute is

Full term babies in the main nurseries were discharged home as usual after an interval of 48 hours from the outbreak, but, in view of the possibility of sequelæ, they were seen every week for a month, with the exception of 2 babies who lived too far away and 2 who had been only slightly affected None of the full term babies developed any abnormal symptom, but some of the more severely affected ones had a raised reticulocyte count, particularly a fortnight after the outbreak, with normal hæmoglobin and red cell counts, which suggests that they had a compensated anæmia A typical example is a baby whose reticulocyte counts one, two, and three weeks after the outbreak were 2 1%, 3 2%, and 2 2%

Premature Babies—Two of these, each weighing 5 lb, were ready for discharge at the time of the outbreak, they were discharged and progressed normally at home Most of the other premature babies showed a reticulocytosis earlier, and to a higher level, than the full term babies, a week after the outbreak one premature baby had a reticulocyte count of 14 6%, and the smallest baby's count was 19 2%, although it had received a blood transfusion The degree of anæmia caused by the poisoning is difficult to assess in these premature infants, because they were all over a month old and already had some anæmia of prematurity, one of them had already been transfused for this before the outbreak But the fall in hæmoglobin seemed to be unexpectedly rapid, and ultimately 4 of these babies needed transfusion, the smallest baby twice The smaller premature babies concerned are still seen regularly and all but one have made uninterrupted progress, the exception being a baby who died two months after the outbreak and was found at necropsy to have ulcerative enteritis, thrombophlebitis of the superior mesenteric and portal veins, and splenomegaly with fibrosis of the Banti type

DISCUSSION

Several reports have been published of methæmoglobinæmia in the nursery from marking ink on diapers The first report was that of Rayner (1886) Kagan et al (1949) reviewed 73 cases in eight outbreaks and added 9 cases of their own

In a major outbreak in 1944 (Graubarth et al 1945), when 17 babies were affected in a nursery containing 32, certain symptoms were described which were not observed in any of our cases, including reduction in intensity of the cry, accelerated or difficult respiration, vomiting, abdominal distension, relaxed stools, jaundice, and hæmaturia There were 4 deaths, 3 being in premature babies, and 3 of the babies that died had bronchopneumonia Methylene blue was not thought to accelerate the rate of recovery

In another reported outbreak (Scott et al 1946), involving 32 babies, one premature infant died The same report describes further cases due to newly marked cloths used in washing the excoriated buttocks of 3 infants with relaxed stools, the first case to present in our outbreak was the only baby in the premature ward with sore buttocks Scott et al describe a case treated with methylene blue which completely recovered from the cyanosis within an hour

The outbreak described by Kagan et al (1949) was in a premature baby unit, 9 babies were affected, some of them considerably younger than ours, and apathy, vomiting, and anorexia were the main symptoms They suggest that the babies having ascorbic acid as a routine may have been protected from the toxic effects of the dye Bronchopneumonia followed in 5 of their 9 cases, at intervals of two to four weeks from the methæmoglobinæmia, whereas none of the unaffected babies in the ward had pneumonia in the same period.

CONCLUSIONS

The risk of absorption of marking ink should be more widely known and more readily considered in cases of cyanosis in infants We were fortunate to discover the toxic factor so soon, and, in view of the number of premature infants involved, we were lucky to have so few complications

To prevent similar outbreaks the makers of the marking ink now print a warning on their bottles that marked articles, particularly infants' clothing, must be laundered before use

SUMMARY

An outbreak of methæmoglobinæmia is described, involving a premature baby unit and the nurseries of a maternity hospital

The cause was the absorption of aniline dye from marking ink on newly marked napkins which had not been laundered

I am indebted to Dr V Mary Crosse for permission to publish this paper and for help in its preparation, and to Dr H Baar and Miss A Gillanders for pathological investigations

ALTHOUGH familial idiopathic methæmoglobinæmia is regarded as very rare, we have been able to report seven cases in two families (Barcroft et al. 1945, Gibson and Harrison 1947) and have described their treatment with ascorbic acid Later Gibson (1948) concluded that a deficiency of diaphorase I (co enzyme factor I) in the erythrocytes was responsible for the symptoms Evidence was presented that diaphorase I is an essential link in the chain of oxidation enzymes which maintains the hæmoglobin in normal persons in a functional state These conclusions were necessarily based on the study of cases from only two families Two further cases have now come to our notice, and we have made tests on them which extend the experimental basis for the hypothesis already put forward The results of these investigations, together with the successful treatment of the patients, are reported here

A further reason for publishing details of these cases of methæmoglobinæmia is the current interest in cyanotic children We have now investigated nine cases from the north of Ireland, and it seems possible that familial methæmoglobinæmia is not so exceedingly rare as is generally believed. The differential diagnosis (by clinical and spectroscopic methods) between this condition and congenital cyanotic cardiac disease may thus be of more than academic importance

TWO CASES

Case 1—A boy, aged 6 years, was brought to the cardiac department of the Royal Belfast Hospital for Sick Children on Feb 14, 1950 with a request from his mother for "the blue baby operation" He had been blue since birth, and case illustrated the therapeutic efficacy of intravenous methylene blue.

EPIDEMIC OF ANILINE METHÆMOGLOBINÆMIA IN NEWBORN BABIES

BETTY E HOWARTH

M B Lond, M R C P, D C H

PÆDIATRIC REGISTRAR, SORRENTO MATERNITY HOSPITAL AND PREMATURE BABY UNIT, BIRMINGHAM

ON Easter Tuesday, 1950, one of the babies in the Sorrento Premature Baby Unit was reported to be having a cyanotic attack after her 10 P M feed. This baby, who was 7 weeks old and weighed $4^1/_2$ lb (birth weight 2 lb 15 oz), was accustomed to take her feeds well and was not subject to cyanotic attacks. She was afebrile, her stools were normal, and there was no evidence of infection or other abnormal physical sign apart from the cyanosis. She was treated as a case of vomit inhalation—by posture, aspiration, oxygen, and prophylactic penicillin.

Two hours later another premature baby was found to be cyanosed after the midnight feed. This baby, who weighed 2 lb 13 oz at 4 weeks (birth weight 2 lb 3 oz), still required some tube feeds and was liable to have cyanotic attacks after them, so she was treated in the usual way. It was noted that the first baby, after two hours in an oxygen tent, had not recovered from her cyanosis but seemed in no way distressed.

Daylight next morning revealed several more blue babies in the Premature Unit, 3 were mildly affected, 4 more severely, and the 2 who had been in oxygen tents all night were now deeply cyanosed. In the severe cases the babies were a slaty grey blue colour, they were restless and looked rather anxious but cried lustily on examination and took their feeds as readily as usual. There was no evidence of infection in any case, and respiration rates and temperatures were normal.

The blue babies were segregated from the rest and specimens of blood were sent for spectroscopic examination to find out whether the cyanosis was caused by methæmoglobin or sulphæmoglobin.

At this point reports of other cyanosed babies began to come in from the nurseries of the main hospital. By midday 23 cases had appeared in the whole hospital 9 in the premature unit, 4 on each floor of the main block, and 6 in a separate ward. There remained two wards in which there were no cases, one being the isolation ward and the other a separate block well away from the main hospital. All the affected babies seemed well, apart from their colour, and were feeding normally.

Various precautionary measures were taken, no mothers and babies were discharged from the hospital, no cases were admitted from the labour ward to an affected ward, and all the babies attending the premature baby follow up clinic were seen in the antenatal clinic and not allowed into the premature block.

In the early afternoon a discussion of the possible toxic factors was held.

Water was unlikely because, though all the wards had the same water supply, two had no cases of cyanosis.

Feeds were excluded because most of the full term babies were fully breast-fed and the affected premature babies were taking several different feeds.

Drugs. There had been no recent new issue of any of the vitamin preparations which were the only drugs in common use in all the wards.

Linen. All the hospital linen is laundered together, so it could be a source of some common toxin.

At this point the pædiatrician recalled a chance remark made to her earlier in the day—that newly marked linen might have been issued for use before being laundered. This led at once to the discovery that, owing to a shortage of napkins when the laundry was closed for Easter, new unwashed napkins had been issued to the wards on Easter Tuesday, they had been marked during the previous week.

Some of the affected babies were thereupon examined and found to be wearing brand new napkins marked "SORRENTO" with thick marking ink in letters often over an inch high. The wards with no blue babies were the ones which had not run short of napkins over Easter and were still using an old issue. All the new napkins were immediately collected and the mothers of the blue babies were told the full details of what had happened.

A sample of the marking ink was sent to the city analyst, who reported that it contained aniline black, or a similar dye, dissolved in aniline.

TREATMENT

The laboratory reported methæmoglobin absorption bands on spectroscopy of the blood from 4 of the most severe cases. The babies were then divided into three groups, each containing premature and mature babies and, so far as possible, babies with different degrees of cyanosis.

The *first group*, of 4 babies (3 premature and 1 full term), received a 1% solution of methylene-blue intravenously, the dose for the premature babies being 1 ml and for the mature baby 2 ml.

The *second group*, of 9 babies (3 premature and 6 full term), were given 50 mg ascorbic acid by mouth before each feed. (The hospital routine is to give to all premature babies 100 mg of ascorbic acid daily from the first week of life.)

The *third group*, of 10 babies (3 premature and 7 full term), were left without treatment as controls.

It had been intended to treat more babies with methylene blue, but by the time the later ones could be treated they had already improved so much after removal of the affected napkins that venepuncture was no longer justified, and they were therefore included in the control group.

The smallest premature baby was given both methylene blue and ascorbic acid, because she was very severely affected and her weight (2 lb 13 oz) also made intensive treatment advisable.

PROGRESS AFTER TREATMENT

The babies treated with methylene blue intravenously responded dramatically, improvement could be seen within a few minutes of the end of the injection, and the babies' appearance was completely normal within an hour. The ascorbic acid and control groups recovered at about equal rates but more slowly than the methylene blue group.

Specimens of blood collected first thing next morning from babies in all three treatment groups showed no methæmoglobin band on spectroscopy. Some specimens of urine collected twenty four hours after the outbreak contained *p* amidophenol, a breakdown product of aniline.

can be safely used in cases in which unmodified E C T would be contra-indicated. It has the advantage of not producing confusion

I am indebted to Dr Thomas Beaton, physician superintendent, St James Hospital, Portsmouth, for permission to carry out the original investigations and to Dr J Hamilton and Dr H. B C Sandiford, consultant anæsthetists, for technical advice and assistance

VITAMIN-B DEFICIENCIES AFTER GASTRIC OPERATIONS

RICHARD WELBOURN
M.B Camb, F R C S
RESEARCH ASSISTANT, DEPARTMENT OF SURGERY, UNIVERSITY OF LIVERPOOL

ROBERT HUGHES
M.D Lpool, M.R C.P
ASSISTANT PHYSICIAN, UNITED LIVERPOOL HOSPITALS

CHARLES WELLS
M.B Lpool F.R C S
PROFESSOR OF SURGERY IN THE UNIVERSITY OF LIVERPOOL

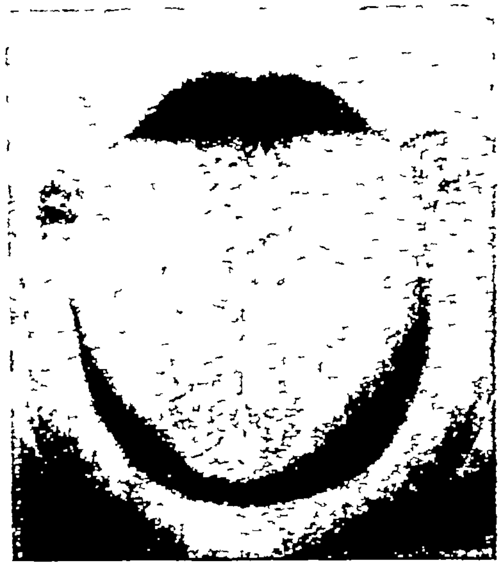
IN our studies of the results of gastric operations (Welbourn 1950, Wells and Welbourn 1951) we have been impressed by the number of patients who developed symptoms and signs of vitamin-B deficiency In a few —e g, cases 3 and 8 below—the manifestations of deficiency appeared while the patient was on a peptic-ulcer diet, but in most patients they did not develop until a year or more after operation.

The possibility of vitamin B deficiencies as sequelæ is no contra indication to surgery in suitable cases, for as a rule the syndromes are easily recognised and readily corrected in their early stages Subtotal gastrectomy is one of the most satisfactory routine operations of general surgery (Wells and Brewer 1948), and besides relieving the primary condition it often greatly improves the patient's nutrition—for example, in one reported case, pellagra resulting from carcinoma of the stomach was cured by gastrectomy (Bean et al 1944) Nevertheless, unsuspected deficiencies of vitamin B are probably causing a great deal of unnecessary disability in patients whose gastrectomies would otherwise be wholly successful.

In the hope of drawing attention to the various forms that postoperative B complex deficiency may take, we are describing the manifestations we have encountered, with some illustrative cases The diagnoses have been established by the clinical features, the response to specific therapy, and the results of biochemical tests, the details of which will be published separately

RIBOFLAVINE DEFICIENCY

The syndrome we have seen most often is hyporiboflavinosis, either alone or associated with other deficiencies Browne and McHardy (1943) described 2 cases of this syndrome following gastrectomy, and 4 cases were reported by Adlersberg and Hammerschlag (1947) the superficial glossitis which Gordon Taylor et al. (1929) noted after gastrectomy was also probably caused by riboflavine deficiency The main lesions (see figure), which were described by Sebrell and Butler (1939) and by Kruse et al. (1940) are



Superficial glossitis and angular stomatitis typical of riboflavine deficiency, developing after subtotal gastrectomy

(1) Cheilosis (peeling of the lips)
(2) Angular stomatitis (transverse fissures at the corners of the mouth)
(3) Superficial glossitis

These are not necessarily all present at the same time Other features, such as dermatitis of the nasolabial folds and scrotal or vulval dermatitis, have not been prominent in the cases we have seen It has not been possible to have our patients examined routinely by slit lamp microscopy for corneal vascularisation, but this lesion was found in case 8

The following 2 cases are typical examples of riboflavine deficiency

Case 1 —A housewife, aged 50, had had dyspepsia due to a chronic duodenal ulcer for many years The ulcer remained active in spite of medical treatment Subtotal gastrectomy was performed in 1942 with an excellent result, except for occasional slight bilious vomiting but a year or so after the operation she began to have cracks at the corners of her lips and a sore tongue, which persisted.

On examination (Oct 2 1950) slight peeling of the lips and angular stomatitis were found The tip of the tongue was red. A blood film was normal, and Hb was 100% (14 8 g per 100 ml.)

Treatment was with riboflavine 3 mg by mouth t d.s.

Progress —The mouth lesions healed completely in two weeks and riboflavine was stopped after five weeks.

Follow-up —The mouth lesions remained healed on Feb 12 1951 (For further details see table)

Case 2 —A seaman, aged 42 had had a duodenal ulcer with dyspepsia intermittently since youth his occupation prevented him from following an ulcer régime Subtotal gastrectomy had been done in 1947 with an excellent result and he had returned to sea. At first his only symptoms were slight nausea and bilious regurgitation after a large meal, but for the past two months he had had a sore tongue ("feels as if surface has gone ') and had been getting worse

On examination (June 2 1950) his tongue was smooth and red in the anterior two-thirds, with prominent fungiform papillæ A blood-count showed red cells 3,600,000 per c.mm Hb 58% (8 6 g per 100 ml), a film showed hypochromia.

Treatment was with riboflavine 3 mg daily by mouth.

Progress —The condition continued to deteriorate for about two weeks and angular fissures appeared it then suddenly started to improve On June 29 there was no soreness or other findings and agrees with the view generally held that familial methæmoglobinæmia is inherited as a recessive character

SUMMARY

Two cases of familial idiopathic methæmoglobinæmia are described

The erythrocytes showed an abnormally low capacity to reduce methæmoglobin in the presence of glucose or lactate

The hæmolysed cells were assayed for activity of diaphorase I (co enzyme factor I), and shown to be deficient as compared with normal controls

The patients were treated successfully with methylene blue and ascorbic acid

NON-CONVULSIVE STIMULATION THERAPY

A NEW PSYCHIATRIC TREATMENT

W Liddell Milligan
M D, B Sc Glasg
CONSULTANT PSYCHIATRIST, ST GEORGE'S HOSPITAL, MORPETH, LATE DEPUTY PHYSICIAN SUPERINTENDENT, ST JAMES' HOSPITAL, PORTSMOUTH

SINCE the inception of electroconvulsive therapy (E C T), various attempts have been made to reduce the severity of the convulsion by using different types of current or by altering their wave form (Liberson 1947, Wilcox 1946, Liberson and Wilcox 1945)

Wilcox (1948) describes the Reiter apparatus which gives "modulated brief spiked impulses", but the technique is somewhat complicated, and, unless an initial convulsion is induced, is unpleasant to the patient (Alexander 1950)

Electronarcosis, first described by Leduc (1902) and developed by van Harreveld (1934, 1937, 1944, 1945), was finally proved clinically feasible by Tietz (1946) A modification in the onset of the convulsion was described by Tietz (1947) and a further advance was recorded by Paterson (1948) and Milligan (1948) This indicated that it was possible to produce a smooth convulsion in which the clonic stage is completely masked Some workers believe that electronarcosis could be produced without preliminary convulsion, and investigations are proceeding, but it seems likely that the apparatus will be elaborate

My own effort to devise a form of electrical treatment of a non convulsive type began in 1947 after Heath and Norman (1946), using 8 mm electrodes, had indicated the probability that a convulsion is not essential in order to gain benefit from electric therapy They attributed the benefit to hypothalamic stimulation, and this is supported by Gellhorn (1950)

To study the effects of a current of low milliamperage, a simple electrical device was constructed at St James Hospital, Portsmouth Using 50 cycle alternating current, this machine gave an output of 0–30 mA Applying an E C T headband to my head, I noted that at 1 mA a slight pricking sensation was felt below the electrodes As the current was increased, the sensation became more severe and seemed to extend in area until at 10 mA it became moderately painful A reddish flicker appeared before the eyes (consistent with 50 cycle frequency) and occasional blue radiating lines were observed After a few minutes, one could become quite used to the sensation and it was possible to read The current level could then be raised slightly, but the absolute maximum was 15 mA, when the burning sensation became almost unbearable It was therefore obvious that for clinical purposes 10 mA was the maximum

A series of depressed patients—mainly elderly—were treated by passing a current of 8–10 mA for one to two hours No striking results were anticipated with such a low current, but though really deep depressions remained unaltered, some of the more moderate types were relieved and several cases of senile anxiety and agitation were benefited These reactions gave rise to the hope that much more might be achieved if a higher level of current could be employed, but obviously this required a general anæsthetic Inspiratory stridor presented the main difficulty, and intravenous thiopentone and tubocurarine eventually proved to be the most successful combination, when the current did not exceed 90 mA, 10–15 mg of curare was sufficient, but above this level full curarisation and passage of an endotracheal tube was necessary

Using a standard time of fifteen minutes, the effect of varying milliamperage levels was tried on a series of patients in whom the main symptom was depression Thus, currents of 50, 70, 85, and 110 mA were employed, ten patients being treated in each case The most consistent results were obtained at 85 mA and this level was adopted for all subsequent treatments

Technique—The machine used is the Shotter Rich model described by Paterson and Milligan (1947), except that the electrodes are of special construction They consist of silver gauze circles, 2 in in diameter, mounted on 'Sorbo' rubber and incorporated in a rubber headband Electrocardiograph contact paste is used

The patient is given atropine gr $^1/_{75}$ by injection and 'Seconal' gr $1^1/_2$ by mouth, half an hour before treatment As no convulsion occurs, precautions are merely those advocated for general anæsthesia, except that it is advisable to remove metal objects from the hair The patient need not leave his own bed, and, as there is no sound save that of deepened respiration, the treatment can if necessary be carried out in a ward behind screens Thiopentone (0 6–0 8 g) and tubocurarine (10–15 mg) are injected intravenously, and, when the patient loses consciousness, the headband is applied The current is slowly raised to 85 mA (in two to three seconds) and if the correct amount of tubocurarine has been given the patient begins to breathe The only indication that the current is passing is a slight spasm of the facial muscles, the rest of the musculature being atonic In some cases it is helpful to stimulate respiration by increasing the current level to 110 mA and dropping it rapidly to 85 mA 'Carbogen' inhalation should be given, but this can be discontinued after a few minutes The current level is reduced to zero after fifteen minutes and the patient usually awakens about half an hour later Complaints of headache are uncommon and patients who have experienced nausea and vomiting after E C T show no ill effects following treatment By connecting pairs of electrodes in series it is possible to treat two or even three patients simultaneously

Physiological Concomitants—The reactions are similar to those described by Rees (1949) in electronarcosis, except that the effect on the cardiovascular system is less The average increase in blood pressure is 20–30 mm Hg systolic and 10–15 mm Hg diastolic Lymphocytosis and rise in blood sugar are comparable to those following electronarcosis

Thirty patients suffering from depression have received this treatment, with improvement in each case An average of 10–12 treatments were required, the response on the whole being less rapid than with E C T On the other hand, agitation was usually relieved after one or two treatments and early relapse was observed less often than with E C T

Fifteen paraphrenics responded well, the most agitated and vehement becoming calmer and taking less interest in their delusions, in ten of these cases a complete remission followed Paranoid schizophrenia seemed to respond particularly well, good remissions resulting in eight out of ten patients treated An average of 15 treatments was required in the paraphrenic and schizophrenic groups

The method may seem cumbersome compared to E C T, but it is less likely to cause complications and can be safely used in cases in which unmodified E C T would be contra-indicated It has the advantage of not producing confusion

I am indebted to Dr Thomas Beaton, physician superintendent, St James Hospital, Portsmouth, for permission to carry out the original investigations, and to Dr J Hamilton and Dr H B C Sandiford, consultant anæsthetists, for technical advice and assistance

PROFESSOR OF SURGERY IN THE UNIVERSITY OF LIVERPOOL

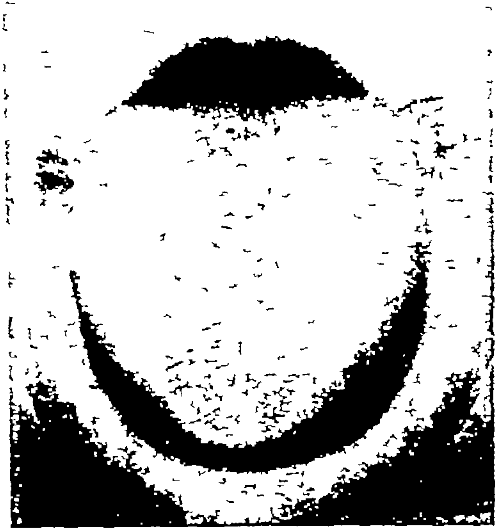
IN our studies of the results of gastric operations (Welbourn 1950, Wells and Welbourn 1951) we have been impressed by the number of patients who developed symptoms and signs of vitamin-B deficiency In a few —e.g, cases 3 and 8 below—the manifestations of deficiency appeared while the patient was on a peptic ulcer diet, but in most patients they did not develop until a year or more after operation.

The possibility of vitamin B deficiencies as sequelæ is no contra indication to surgery in suitable cases, for as a rule the syndromes are easily recognised and readily corrected in their early stages Subtotal gastrectomy is one of the most satisfactory routine operations of general surgery (Wells and Brewer 1948), and besides relieving the primary condition it often greatly improves the patient's nutrition—for example, in one reported case, pellagra resulting from carcinoma of the stomach was cured by gastrectomy (Bean et al. 1944) Nevertheless, unsuspected deficiencies of vitamin B are probably causing a great deal of unnecessary disability in patients whose gastrectomies would otherwise be wholly successful.

In the hope of drawing attention to the various forms that postoperative B complex deficiency may take, we are describing the manifestations we have encountered, with some illustrative cases. The diagnoses have been established by the clinical features, the response to specific therapy, and the results of biochemical tests, the details of which will be published separately

RIBOFLAVINE DEFICIENCY

The syndrome we have seen most often is hyporiboflavinosis, either alone or associated with other deficiencies Browne and McHardy (1943) described 2 cases of this syndrome following gastrectomy, and 4 cases were reported by Adlersberg and Hammerschlag (1947), the superficial glossitis which Gordon Taylor et al. (1929) noted after gastrectomy was also probably caused by riboflavine deficiency The main lesions (see figure), which were described by Sebrell and Butler (1939) and by Kruse et al. (1940) are



Superficial glossitis and angular stomatitis typical of riboflavine deficiency developing after subtotal gastrectomy

(1) Cheilosis (peeling of the lips)
(2) Angular stomatitis (transverse fissures at the corners of the mouth)
(3) Superficial glossitis

These are not necessarily all present at the same time. Other features, such as dermatitis of the nasolabial folds and scrotal or vulval dermatitis, have not been prominent in the cases we have seen It has not been possible to have our patients examined routinely by slit lamp microscopy for corneal vascularisation, but this lesion was found in case 8

The following 2 cases are typical examples of riboflavine deficiency

Case 1 —A housewife aged 50, had had dyspepsia due to a chronic duodenal ulcer for many years The ulcer remained active in spite of medical treatment Subtotal gastrectomy was performed in 1942 with an excellent result, except for occasional slight bilious vomiting, but a year or so after the operation she began to have cracks at the corners of her lips and a sore tongue, which persisted

On examination (Oct 2 1950) slight peeling of the lips and angular stomatitis were found The tip of the tongue was red. A blood film was normal and Hb was 100% (14 8 g per 100 ml)

Treatment was with riboflavine 3 mg by mouth t d.s.

Progress —The mouth lesions healed completely in two weeks and riboflavine was stopped after five weeks

Follow up —The mouth lesions remained healed on Feb 12, 1951 (For further details see table)

Case 2 —A seaman, aged 42, had had a duodenal ulcer with dyspepsia intermittently since youth his occupation prevented him from following an ulcer régime Subtotal gastrectomy had been done in 1947 with an excellent result and he had returned to sea. At first his only symptoms were slight nausea and bilious regurgitation after a large meal but for the past two months he had had a sore tongue ('feels as if surface has gone ') and had been getting worse

On examination (June 2 1950) his tongue was smooth and red in the anterior two thirds, with prominent fungiform papillæ A blood count showed red cells 3,600,000 per c.mm, Hb 58% (8 6 g per 100 ml), a film showed hypochromia

Treatment was with riboflavine 3 mg daily by mouth.

Progress —The condition continued to deteriorate for about two weeks, and angular fissures appeared, it then suddenly started to improve On June 29 there was no soreness or other symptom of hypovitaminosis The tongue was less smooth and less red Treatment with riboflavine was continued and ferrous sulphate gr 6 t d s by mouth started

Sept 5 improvement was maintained The tongue was normal, apart from considerable oedema of its margin Treatment with riboflavine and iron was continued

Sept 29 improvement was maintained The oedema of the tongue had nearly gone Hb was 101% (14 9 g per 100 ml) and a film was normal Treatment with riboflavine was continued, but the iron was stopped

Feb 5, 1951 the tongue was normal (for further details see table)

We have seen patients with apparently similar lesions who have not responded to riboflavine To many of them we have also given nicotinic acid, pyridoxine, pantothenic acid, iron, and 'Marmite' (Lindeboom 1950), but in case 8 only was there any improvement, and this seemed to be due to pyridoxine We have another patient—a man—who has developed glossitis, cheilosis, and dysphagia (a Plummer Vinson syndrome) since his gastrectomy He has no organic lesion in the throat, his peripheral blood is normal, and he has not responded to riboflavine, nicotinic acid, or 'Becosym' * by mouth The cause of the lesions in these patients remains obscure

ANEURINE (VITAMIN B_1) DEFICIENCY

We have seen several syndromes which we believe to be due to aneurine deficiency, but have seen no case of cardiac failure due to it

Established Peripheral Neuritis

Cases 6 and 8 (see below) had peripheral neuritis and other lesions In the following case peripheral neuritis had developed before any operation was done on the stomach, but it had progressed, and the nutritional state as a whole deteriorated, after gastrectomy Although megaloblastic pernicious anaemia ultimately developed, the neurological signs were more consistent with peripheral neuritis than with subacute combined degeneration of the cord

Case 3 —A housewife, aged 53, had been healthy in 1943, when she weighed 10 stone and was working actively At this time she had first noticed symptoms of duodenal ulceration with stenosis By 1946 she had atrophic gastritis and histamine fast achlorhydria, and had developed a deficiency state consisting of (1) severe iron deficiency anaemia (Hb 20% (3 g per 100 ml), red cells 1,500,000 per c mm , marrow probably hypoplastic) , (2) cheilosis, angular fissures, glossitis, and stomatitis , (3) pins and needles in the arms and legs , hyperaesthesiae of the soles , ankle jerks sometimes present and sometimes absent , and impaired vibration sense in the legs , (4) oedema of the ankles (serum proteins 5 5 g per 100 ml) , and (5) loss of 4 stone in weight Iron, liver, and injections of unspecified vitamin had caused some improvement In October, 1947, when we first saw her, she had had an exploratory laparotomy, a gastro enterostomy and an entero anastomosis, but continued to have pain and vomiting, and was considered to have a stomal ulcer and a partial obstruction

Operations —Subtotal gastrectomy was done on Oct 24, 1947 The stoma was thickened, but no organic obstruction was found After operation the pain was relieved, but vomiting continued, and two further operations for chronic small bowel obstruction were done in the next three years

Progress and Treatment —There was no real improvement, and the intake of food became greatly reduced The deficiency state progressed steadily The anaemia became pernicious in type within a year of gastrectomy (Hb 76% (11 2 g per 100 ml) red cells 2,510,000 per c mm , colour index 1 51, marrow megaloblastic) and responded to liver injections The mouth lesions responded to treatment with vitamin B complex The nervous lesions progressed Pins and needles continued, but stopped temporarily after injections of aneurine Walking became very difficult, the ankle jerks and abdominal reflexes disappeared completely, the pupils became unequal, and gross Rombergism developed The oedema disappeared temporarily after aneurine injections The serum protein level was 5 9 g per 100 ml on one occasion when oedema was present. Another stone in weight was lost, and the patient became much emaciated Diarrhoea with steatorrhoea (70% absorption) developed

Follow up —In December, 1950, the patient was still alive but had moved to another district

Incipient Peripheral Neuritis

It has been observed (Spillane 1947) that, in countries in which beriberi is endemic, some people experience symptoms—e g , tingling in the extremities, muscle cramps, and a feeling of heaviness in the limbs—without developing any objective signs of neuritis These symptoms are also common in the earliest stages in those who develop frank beriberi (Smith 1946) Cases 3 and 8 had symptoms of this type for some years before more serious trouble developed We have seen several other patients who have developed these symptoms, and they have usually been relieved by aneurine In none of them have reflexes been lost or sensation diminished , but, if they had not been treated, we believe that they might well have developed frank peripheral neuritis Hyporiboflavinosis has been seen in some of these patients

Muir (1949) records a similar condition "It was found that many patients following gastrectomy suffered from painful legs and not a few of these showed oedema of the ankles " They were rapidly cured with aneurine *His cases differ from ours in that some of them* had areas of hyperaesthesia and diminished and unequal tendon jerks Further, his cases were seen within a year of operation, whereas few of ours developed symptoms until after this period

Cases 4 and 5 are typical of this group Note the time relations between the neuritic symptoms and the vitamin therapy It is clear that in both cases the symptoms were relieved when aneurine was given Other symptoms—e g , "dumping," bilious vomiting, and fatigue—were not influenced by vitamin therapy The patients were not told which symptoms were likely to improve

Case 4 —A man, aged 49, had had a duodenal ulcer for 29 years Subtotal gastrectomy had been done on Jan. 6, 1948, with a good result, apart from a mild "dumping syndrome " (fullness, fatigue, and nausea) and flatulence after large meals These had practically disappeared in 2$^1/_2$ years The patient had been hypertensive (190/100 mm Hg) for ten years, and thoracolumbar sympathectomy was done to relieve severe frontal headaches and giddiness The symptoms were relieved, but the blood pressure was not lowered, by the first stage of the operation

On examination on March 9, 1949, the patient complained of dead fingers and cramps in the legs He had cheilosis, slight angular fissures, and glossitis Nothing abnormal was detected in his nervous system

Treatment —On March 23, vitamin treatment was begun with 'Benerva Co ' † tab 3 *t d s* by mouth

Progress —On April 28, 1949, the paraesthesiae were less and the mouth lesions healed By May 23, 1949, the paraesthesiae had gone, and the treatment was stopped

July 15, 1949 slight angular fissures were present, so the benerva was begun again

Sept 6, 1949 no symptoms or signs of hypovitaminosis were present and the benerva was stopped

March 10, 1950 the patient complained of pins and needles and numbness in hands and feet , muscle cramps in fingers and arms , intermittent peeling of lips, angular fissures, and sore tongue and lack of energy Nothing abnormal was detected in his nervous system A blood count showed red cells 4,600,000 per c mm , and Hb 96% (14 2 g per 100 ml) The serum protein level was 7 05 g per 100 ml A fat balance test showed 88 6% absorbed Radiography after a barium meal showed no significant abnormality A test meal showed achlorhydria E C G normal

Sympathectomy, on April 25, 1950, was followed by a stormy convalescence with chest complications Food intake was reduced and the patient was febrile

---

* 'Becosym' (Roche) contains aneurine 5 mg riboflavine 2 mg , nicotinamide 20 mg pyridoxine 2 mg and calcium pantothenate 3 mg , per tablet We have usually given two tablets three times a day

† 'Benerva Co ' (Roche) contains aneurine 1 mg , riboflavine 1 mg and nicotinamide 15 mg per tablet

May 18 the patient complained of very severe pins and needles, and muscle jerks at night prevented sleep, heaviness and weakness of hands Examination of his nervous system showed slight weakness of grip, but reflexes and sensation normal. Treatment was begun with intravenous aneurine 10 mg initially, followed by 3 mg daily by mouth.

May 22 slight but definite improvement

May 30 very great improvement

June 28 no symptoms of hypovitaminosis

July 6 no symptoms of hypovitaminosis. A blood count showed red cells 4,300,000 per c.mm., and Hb 89% (13 2 g per 100 ml) A blood film showed slight hypochromia and anisocytosis. The serum protein level was 5 85 g per 100 ml The treatment with aneurine 3 mg by mouth daily was continued and treatment with exsiccated ferrous sulphate gr 6 t d.s. by mouth begun.

Oct 5 no symptoms of hypovitaminosis and much more energy than previously Hb 96% (14 2 g per 100 ml.) Blood film normal. Serum protein 6 4 g per 100 ml. Treatment with aneurine was continued, but the iron was stopped. (For further details see table)

Case 5 —A housewife, aged 61 had had a duodenal ulcer for eighteen years and cholelithiasis. Subtotal gastrectomy and cholecystectomy had been done on March 17 with a good result. She had a severe " dumping syndrome " (fullness and fatigue) after meals, and bilious vomiting, but felt very much better than before operation. For three years after the operation she had no teeth or dentures.

On examination on March 3, 1949, she complained of pins-and needles in her hands and feet, angular stomatitis, and glossitis. No abnormality was observed in her nervous system.

Treatment and Progress —On July 8, 1949, in addition to her other symptoms she complained of fatigue Her hæmoglobin was 80% (11 8 g per 100 ml) A blood film showed hypochromia

July 15, 1949 treatment was begun with benerva co tablets 2 t d s by mouth

Aug 18, 1949 the paræsthesiæ and mouth lesions improved, but fatigue persisted The treatment was continued

Sept 23, 1949 the mouth lesions had healed, but the paræsthesiæ and fatigue persisted Hb 88% (13 g per 100 ml) The treatment was continued.

Jan 20 1950 The condition remained stationary The treatment with benerva co was continued, together with aneurine 10 mg daily by mouth and 25 mg twice weekly by intramuscular injection.

March 24 the paræsthesiæ were much less, and fatigue less The treatment was continued

April 25 no paræsthesiæ or mouth lesions, but fatigue persisted Hb 80% (11 8 g per 100 ml) The benerva co was continued but the extra aneurine was stopped, and treatment with exsiccated ferrous sulphate gr 6 t d.s by mouth was started.

June 2 fatigue persisted Hb 84% (12 4 g per 100 ml) Serum protein 5·8 g per 100 ml. Treatment continued

Oct 10 fatigue very much improved while the patient was on holiday, but recurred when she returned home No paræsthesiæ or mouth lesions Hb 94% (13 9 g per 100 ml.) Blood film normal Treatment with iron was stopped, but benerva co continued (For further details see table)

The differential diagnosis of these cases may not be easy The symptoms must be analysed carefully and interpreted in the light of a thorough physical examination and investigations Similar symptoms have been found in some patients with osteo arthritis, cervical ribs, old osteomyelitis, Raynaud's phenomenon, and so on, and in them vitamin therapy has produced no improvement

NUTRITIONAL STATE OF PATIENTS AND FACTORS POSSIBLY AFFECTING IT VITAMIN REQUIREMENTS CALCULATED ON BASIS OF ANEURINE 0 6 MG PER 1000 NON-FAT CALORIES, RIBOFLAVINE, 0 6 MG PER 1000 TOTAL CALORIES AND NICOTINIC ACID 4 MG PER 1000 TOTAL CALORIES (B.M.A. 1950)

Œdema

We have seen œdema of the ankles in some of our patients—e g , cases 3 and 8 All had normal exercise tolerance, heart size, and electrocardiograms, and in none of them was a serum protein level lower than 5 5 g per 100 ml found Œdema was present in some of Muir's (1949) cases after gastrectomy and it disappeared rapidly with aneurine therapy (see above)

Disturbances of Consciousness

Mental symptoms, disturbances of consciousness, and brain stem lesions may be caused by aneurine deficiency Wernicke's encephalopathy, with its classical triad of clouding of consciousness, ophthalmoplegia, and ataxia, is the best known example and it is often associated with various lesions of the stomach (Campbell and Russell 1941) The following 2 cases, occurring after gastrectomy and after vagotomy with gastro enterostomy respectively, belong, we believe, to this group Both also had the lesions of hyporiboflavinosis, and one had early peripheral neuritis Both responded rapidly to intensive therapy with vitamin B complex

Case 6 —A housewife, aged 60, had had a partial gastrectomy in 1944. The result had been good apart from occasional bilious vomiting and attacks of diarrhœa In November, 1947, she had become fretful and light-headed, and found difficulty in concentrating On Jan 8 or 9, 1948, she had suddenly lost consciousness, wandered about in a confused state, and been found lying on the floor next morning On Jan 25 there had been obvious mental disturbance, she had had grandiose ideas and been fretful and uninhibited, with faulty memory She had had a good appetite, but had continued to diet after her operation She had lost a little weight and could not walk

On examination there were slight bilateral papillœdema, slight tremor of the tongue, and hypotonia and incoördination of the limbs The knee jerks were greatly diminished and the ankle jerks absent There was slight loss of superficial sensation at the peripheries of the arms and legs The tongue was pale and smooth The blood pressure varied from 140/80 to 170/100 mm Hg The Wassermann reaction of the blood, the cerebrospinal fluid (C S F), radiography of the skull, and electrocardiograms were normal

Treatment and Progress —She was given intramuscular aneurine 5 mg a day and 'Marmite' and yeast tablets by mouth Her mental condition improved rapidly, the papillœdema disappeared, and the left knee jerk became brisk. She learnt to walk again, but with hesitancy and some ataxia She was discharged after only twelve days' treatment

Follow up —She was seen again five months later Mentally she was, if anything, rather depressed, and the reflexes and sensation in her limbs were normal

Case 7 —A woman, aged 26, had had an abdominal vagotomy in January, 1950, for a prepyloric ulcer After operation she had vomited for a week, after which she had been well for two months when she had started to vomit again

In June, 1950, she was readmitted to hospital and radiography after a barium meal suggested duodenal ileus rather than pylorospasm as the cause of the vomiting The clinical picture was complicated by an emotional upset A posterior gastro enterostomy was done on June 19

Treatment and Progress —The patient continued to vomit everything that she took by mouth, and two weeks later she became hallucinated and uncoöperative She had peripheral circulatory failure, early bilateral papillœdema, and paresis of both 3rd cranial nerves Intravenous fluids and gastric suction produced no improvement, and on July 3 she became comatose Angular fissures developed on the lips On July 4 she received aneurine 50 mg riboflavine 6 mg , and nicotinic acid 50 mg by injection, and next day her mental condition and ocular lesions were much improved Vitamin therapy was continued During the next few days, however, she developed extrarenal azotæmia and hypostatic pneumonia and became pyrexial The level of non protein nitrogen in her blood was 240 mg per 100 ml on July 10, and rose to 375 mg per 100 ml on July 12 At the same time her Hb decreased to 40% (5 9 g per 100 ml), and her serum protein level fell to 4 43 g per 100 ml. She became drowsy again but the ocular lesions did not recur She was treated with intravenous fluids, an intragastric drip of glucose and arachis oil, penicillin, and streptomycin, and transfusions of packed red cells She slowly improved, and by Aug 11 the level of non protein nitrogen in her blood was 30 mg per 100 ml and her Hb 72% (10 7 per 100 ml) Her mental condition improved considerably, and the angular fissures healed Convalescence was interrupted by an abscess in the buttock, but this was drained and was soundly healed by Oct 10, when she was discharged fit for work

PELLAGRA

Pellagra has been described in association with, and apparently secondary to, a great many pathological conditions, including peptic ulcer, carcinoma, and syphilis of the stomach The subject has been reviewed by Levy Simpson (1935) and by Bean et al (1944), who have collected from the literature and reported themselves more than 20 cases following operations of various types for peptic ulcer We have knowledge of several similar cases, but have had the opportunity of studying only two

Case 8 —A widow, aged 60, had developed ulcer dyspepsia in 1920, when she was aged 33 Previously she had been healthy, apart from a corneal ulcer, and weighed 12 stone She had had gall stones and gastric and duodenal ulcers, and undergone a cholecystectomy and four gastric operations, including a subtotal gastrectomy in 1946 About 1928 she had started to have pins and needles and cramps intermittently in the arms and legs, and constant fatigue In 1936 she had had a blow on the head, which had been followed by ? epileptic fits for some years At this time too she had developed headaches and started to have difficulty in remembering recent events Her diet had been fairly adequate up to 1946, when she had had a subtotal gastrectomy, but after this it had been greatly reduced and was deficient in nicotinic acid (see table) In addition she had vomited frequently

In June, 1947, she was thought to have a recurrent gastric ulcer, and underwent another operation No ulcer was found, but a small pyloric remnant was removed At this time she had glossitis and angular stomatitis, and her limbs were beginning to feel heavy and numb, but there were no objective signs of nerve involvement She had a mild iron-deficiency anæmia (Hb 78% (11 4 g per 100 ml)) By June, 1948, she had developed gross signs of deficiency The mouth lesions were more severe There was severe peripheral neuritis with stocking and glove anæsthesia to above the knees and elbows. Some reflexes were reduced but not absent, some were normal and others were exaggerated Position, vibration, and joint sense were reduced in the arms and absent in the legs There was gross Rombergism, and the patient could not walk. She had alternating constipation and diarrhœa and the typical skin lesions of pellagra on the arms and legs Her ankles were œdematous The anæmia had improved after treatment with iron by mouth Hb was 85% (12 6 g per 100 ml) Radiography after a barium meal showed the gastric stump to empty slowly, and a fractional test meal showed achlorhydria An electrocardiogram was normal, and the Wassermann reaction was negative

Treatment and Progress —The patient was given large amounts of aneurine, riboflavine, and nicotinic acid parenterally and marmite by mouth. During the next three months there was a gradual improvement The skin lesions disappeared, and the bowels became more normal The œdema disappeared and the areas of anæsthesia regressed slightly The paræsthesiæ stopped, and she learnt to walk and knit again Before her illness she had knitted without looking but she has never regained this ability The mouth lesions remained active

Follow up —She was not seen again until May, 1950 She had stopped taking vitamins, and her paræsthesiæ and cramps had returned She had constant fatigue and insomnia. The mouth lesions were as bad as ever and she again had alternating constipation and diarrhœa Her skin lesions were minimal, the nervous lesions were largely unchanged, and there was no œdema She had put on a little weight, but still weighed only 7½ stone Her Hb was 88% (13 g per 100 ml), serum protein level 5 65–6 81 g per 100 ml , and serum calcium level 10 15 g per 100 ml On two separate occasions a barium meal reached the cæcum in an hour but a fat balance test showed 95% absorption. There was evidence of corneal vascularisation in the eye which had *not* had a corneal ulcer 'There are vascular loops with secondary arcades at the margins of the cornea, more in the right (the side of the corneal ulcer) than in the left' (Mr A. McKie Reid) The paræsthesiæ and cramps improved temporarily after aneurine by mouth, but later the peripheral neuritis and mouth lesions became active again in spite of aneurine, riboflavine, nicotinic acid, pyridoxine, pantothenic acid, and iron by mouth. In December, 1950, and January, 1951, she was given a course of becosym (2 ampoules daily) by injection, and 'Casydrol' by mouth. She put on a few pounds in weight, and her paræsthesiæ improved steadily. Her mouth lesions improved dramatically at first, but then relapsed again. Pyridoxine 20 mg. t.d.s. by mouth was given as well for three weeks, and the mouth lesions steadily improved, becoming better than they had been for four years. This improvement has been maintained on becosym by mouth alone. (For further details see table.)

The other patient was a man who developed alternating constipation and diarrhœa, and dark pigmentation of the skin of his forehead and the backs of his forearms and hands, two or three years after subtotal gastrectomy. Nicotinic acid 50 mg. t.d.s. by mouth restored his skin to a normal colour within a month but did not affect his bowels.

FATIGUE AND OTHER SYMPTOMS

The early symptoms of pellagra may resemble those of neurasthenia. There may be general fatigue, lassitude, anorexia, irritability, insomnia, depression, loss of weight, and so forth. Very similar symptoms may be caused by experimental aneurine deficiency in man (Williams and Mason 1941, Williams et al. 1939, 1940, 1943, Jolliffe et al. 1939). In this connection the following case is of interest.

Case 9.—A labourer, aged 48, had had a gastro-enterostomy for a duodenal ulcer in 1927. About 1944 his wife had noticed that he was becoming morose; in 1946 he had had several attacks of transient loss of consciousness resembling petit mal; and in 1947 he had become depressed and emotional. He had had double vision on one occasion, been troubled with insomnia, and had a poor appetite.

He was admitted to a mental hospital as a psychotic in March, 1947. He was confused, apathetic, depressed, somewhat disoriented in time, had difficulty in formulating his ideas, and could not find simple words. He had diarrhœa and became incontinent of urine and fæces. He had a bright pink smooth tongue. His gait was a little unsteady, and he had some incoördination in the limbs, but there were no other abnormal neurological signs. A blood-count showed 4 900 000 red cells per c.mm., Hb 75% (11.1 g. per 100 ml.), film normal. The Wassermann reaction of the blood was negative. The C.S.F. was normal.

Treatment and Progress.—Hypovitaminosis was suspected and the patient improved immediately when he was given nicotinic acid 50 mg. four times a day. Later this was increased to 100 mg. three times a day, and benerva co. tab. 2 three times a day was given as well. The patient was discharged cured two months later (report kindly sent by Dr. B. Finkleman).

A year later (August, 1948) he complained of extreme lack of energy and weakness, heaviness, and cramps in the legs. He was depressed and would not mix with the other patients in the ward. There was no diarrhœa or glossitis, and there were no abnormal neurological signs. There was slight œdema of the ankles, and he was underweight. He had received 200 mg. of nicotinic acid intramuscularly daily and benerva co. tab. 2 t.d.s. by mouth for a week before admission without improvement. Examination of the blood showed red cells 4 200,000 per c.mm. and Hb 75% (11.1 g. per 100 ml.). A fractional test-meal showed achlorhydria. Radiography after a barium meal showed that the stomach emptied normally through the gastro-enterostomy stoma. The Wassermann reaction of the blood was negative and the C.S.F. was normal. The patient was given aneurine 20 mg. a day intramuscularly, marmite, and oral iron. His symptoms quickly improved and he became cheerful, energetic, friendly, and most helpful in the ward. He was discharged cured, seven weeks later.

Improvement in the mental condition was produced on the first occasion with nicotinic acid and on the second occasion with aneurine. It seems likely that two separate deficiency states were present on the two separate occasions.

Undue fatigue and lassitude are not uncommon after gastrectomy. They may be present all day or towards the end of the day, and not after meals only, like the symptoms of the efferent loop "dumping syndrome." In some cases—e.g., cases 4, 5, 8, and 9—they are associated with vitamin deficiencies, but even so they are not usually benefited by vitamin therapy. Sometimes they are due to anæmia, hypertension, or other organic causes, and disappear when the underlying condition is corrected. In some of the patients psychological and environmental factors seem to be responsible, but in others there is no obvious cause. The symptoms have been relieved, sometimes dramatically, in some of our patients by giving small doses of *d* amphetamine sulphate ('Dexedrine').

Loss of appetite, according to most workers, is almost constant in beriberi, pellagra, and experimental aneurine deficiency. It is rare after gastrectomy (although a few patients have *morning* anorexia), and only one of our patients with hypovitaminosis (case 9) complained of it. It is difficult to explain this, but at least one large series of cases of beriberi has been reported in which anorexia was almost unknown and constant hunger was the rule (Smith 1946). Loss of weight is common after gastrectomy, and is usually due to causes other than hypovitaminosis (Wells and Welbourn 1951).

DISCUSSION

We have seen and described vitamin B deficiencies after various types of gastric operation, but we have no information about the relative incidence of the deficiency syndromes after the different operations. We have studied in detail a continuous series of nearly 200 patients submitted to subtotal gastrectomy for peptic ulceration. The operation was of the anterior (or occasionally posterior) Polya type with a Hoffmeister-Finsterer Lake valve (Wells and Brewer 1948). In 100 consecutive cases reviewed 1–4 years after operation (including cases 2–5) we found the following conditions:

Conditions	*No. of cases*
Hyporiboflavinosis alone	4
Incipient peripheral neuritis alone	2
Hyporiboflavinosis + incipient peripheral neuritis	3
Hyporiboflavinosis + established peripheral neuritis	1
Total	10 (*10%*)

We have found a similar incidence in a rather smaller and less complete series of patients (including cases 1 and 8) who had the same operation 5–10 years ago. Some of the patients had iron deficiency anæmia as well, but hyporiboflavinosis and incipient peripheral neuritis were often encountered without any other signs of deficiency. Established peripheral neuritis and pellagra have, in our experience, been part of a more severe mixed deficiency syndrome. Our studies of blood pyruvic acid levels suggest that subclinical aneurine deficiency may be a good deal commoner than the established clinical syndromes (R. B. Welbourn and D. M. Chesterman, unpublished data).

A 10% incidence of cases of vitamin B deficiency after gastrectomy requires an explanation. It has been pointed out (Spies 1943, Riggs et al. 1944) that the usual ulcer régimes are deficient in several essential foods, including the vitamin-B complex. Other factors—e.g., vomiting, bleeding, and alkaline therapy—may further reduce the body's stores; and, although frank vitamin-B deficiency is rare in the course of peptic ulceration, many people may be potentially deficient by the time they come to operation. Thereafter several new factors are introduced, and we must consider in turn the possible mechanisms by which the deficiencies may develop.

Deficient Intake of Food

Postoperatively some patients (especially those subjected to gastrectomy) develop symptoms—e.g., bilious vomiting and the "dumping syndrome"—which seriously reduce the amount of food which they can eat

Four patients (cases 1 and 4–6) in the present series had these symptoms On the other hand, other patients whom we saw with very severe symptoms had no signs of deficiency Others vomit a proportion of the food which they eat, thus reducing their effective intake This was an important factor in some of our most severe deficiencies (cases 3, 7, and 8)

One of the advantages of subtotal gastrectomy is that it allows patients to return to a normal mixed diet, and analysis of our patients' diets shows (see table) that, though some had a very low total calorie intake, the vitamin B content of their food was usually more than adequate There is evidence that the requirement of aneurine is directly related to the intake of "non fat calories," and that the requirements of riboflavine and nicotinic acid are to some extent related to the total caloric intake (British Medical Association 1950) In the table we have shown the actual intake of vitamins compared with the requirements, calculated on this basis In only two instances was there deficiency of nicotinic acid (cases 5 and 8), and in every case there was an adequate amount of aneurine and riboflavine These cases are in every way typical, hence causes other than reduced intake of vitamins must be sought to explain the deficiencies

Interference with Absorption of Vitamins

We discuss elsewhere (Wells and Welbourn 1951) the physiological effects of operations on the stomach, and emphasise the importance of the intestinal hurry which may result from gastrectomy It is likely that by interfering with the digestion and absorption of food this contributes to the development of vitamin deficiencies (cases 3, 4, 6, and 8)

Another mechanism is suggested by the work of Petri and Wanscher (1937), Petri et al (1937), and Sydenstricker et al (1936), who have found that neutralised gastric juices, taken by mouth, will greatly improve pellagra in man In experiments on dogs and pigs Petri (1936) and Petri et al (1938a and b, 1940, 1943, 1944a, b, and c) have shown that "gastroprival" pellagra is caused constantly by total gastrectomy or by excision of the fundus (middle portion) of the stomach alone This can be prevented by *neutralised* normal gastric juice in dogs (but not in pigs) and by pyridoxine (vitamin B_6) in both dogs and pigs Nicotinic acid had no effect except in one pig which had had a pylorectomy only These experiments suggest that the stomach plays some part in the absorption or utilisation of nicotinic acid and of pyridoxine The fact that the gastric juice in these experiments was neutralised indicates that the effect was not due to its acidity

Destruction of Vitamins

Both aneurine and riboflavine are stable in acid media only, and achlorhydria may allow appreciable quantities of the vitamins to be destroyed before they can be absorbed The hydrochloric acid secreted by the stomach normally provides a strongly acid medium for the gastric phase of digestion, and the pH of the stomach contents is usually about 2 Chyme is rapidly diluted and neutralised in the duodenum, and finally passes through the jejunum and ileum at an approximately neutral reaction (pH 6–8) A subtotal gastrectomy usually produces complete achlorhydria (as in cases 1–5, 8, and 9), and food passes through the gastric stump and small intestine at this same neutral reaction (Wells and Welbourn 1951) Strongly alkaline reactions are not encountered

In vitro experiments (Melnick et al 1941) show that aneurine is stable in normal gastric juice at a pH of 1 5–8 0, but that up to 50% may be destroyed by incubation with bile or pancreatic juice at a pH of 8 0–8 5 At pH 4 5 no aneurine is destroyed This suggests that there may be a stabilising factor in normal gastric juice Riboflavine is also unstable in an alkaline medium, but its exact behaviour in the intestinal secretions has not, so far as we know, been worked out in the same detail as that of aneurine Nicotinic acid is stable over a wide pH range The significant facts about aneurine, and probably riboflavine also, are that in the normal alimentary tract they are kept at a stable acid reaction until they enter the small intestine, where they are rapidly absorbed After gastrectomy the whole process of churning, liquefying, and diluting the food is done at the neutral reaction of the small intestine, and under these conditions appreciable quantities of the vitamins may be inactivated We are trying the effect of hydrochloric acid alone on some patients, and have cured hyporiboflavinosis in one

Diversion of Vitamins to Bacteria

Frazer (1949) has drawn attention to the fact that achlorhydria allows the colon organisms, which normally inhabit the colon and lower ileum only, to grow all the way up the small intestine He believes that in the sprue syndrome vitamin deficiencies are caused largely by these bacteria diverting the B vitamins to their own use, thus depriving the host It is possible that this is a contributory factor in the development of hypovitaminosis after gastrectomy We have found that a free growth of *Bact coli* and other common colon organisms can be obtained from the gastric contents in about half the patients who have undergone subtotal gastrectomy, but we have not found organisms constantly in the patients with vitamin deficiency A free growth of *Bact coli* was obtained from only one (case 4) of the cases described It should be possible to test this hypothesis by giving intestinal antiseptics, but we have not yet done so

Another way in which bacterial growth may contribute to hypovitaminosis is suggested by Brain (1950) He has found acute ulcerative stomatitis, apparently due to B complex deficiencies, in the early postoperative stage after total gastrectomies, and most of the cases have been in patients who had gross sepsis—e g , empyema He suggests that the bacteria in these lesions divert to their own use some of the B vitamins from the host, thereby producing a deficiency

Prevention and Treatment of Deficiencies

It is important to encourage patients to eat meat, bacon, and other foods—e g , eggs, fruit, green vegetables, and brown bread—which contain adequate quantities of vitamins and iron It is wise to recommend marmite or some other source of the whole B complex regularly as a prophylactic against vitamin B deficiencies

Patients with established deficiencies require specific therapy For the purpose of investigation we have treated many of our cases with small doses of one specific factor at a time But since several deficiencies may be present, and since administration of one member of the B complex may precipitate deficiency of another (Frazer 1949), it seems better to give routinely a vitamin B compound preparation The dosage should be large, because of the possible destruction in the intestine Individual vitamins may be given in addition when they are indicated Most of the mild cases respond rapidly, but in resistant or acute cases the vitamins should be given parenterally

SUMMARY

Vitamin-B deficiencies are relatively common after gastric operations and have been found in 10% of subtotal gastrectomies one or more years after operation

Hyporiboflavinosis and incipient peripheral neuritis, due to aneurine deficiency, are the commonest syndromes Less common conditions are established peripheral neuritis, Wernicke's encephalopathy and other disturbances of consciousness, and pellagra

In most cases the diets contain sufficient vitamin B Achlorhydria, which encourages destruction of aneurine and riboflavine and may allow diversion of vitamins to intestinal bacteria, is possibly the chief cause of the deficiencies Vomiting and intestinal hurry may be contributory factors

After gastric operations foods rich in vitamin B should be advised The deficiency states can be easily corrected in their early stages

We wish to thank Dr J F Wilkinson for information about case 3, Mr J Cosbie Ross and Mr James Gow for permission to report case 7, Dr B Finkleman for information about case 9, Mr W Lee, of the central photographic department in the University of Liverpool, for the photograph, Dr Fred Wrigley, of Roche Products Ltd, for helpful advice and criticism and for supplying vitamin preparations, and Miss E M Winstanley for her help with the diet analyses

ACTINOMYCOSIS OF THE SPINE

M E WINSTON
M.B Edin F R C S.E

SENIOR ORTHOPÆDIC REGISTRAR, SOUTH MANCHESTER HOSPITAL GROUP

ACTINOMYCOSIS of the spine is a rare disease In a study of 678 cases of actinomycosis, Sanford (1923) reported only 4 involving the vertebræ and ribs

The diagnosis is not usually recognised until late, the great majority of cases being found at necropsy This is partly due to the fact that spinal symptoms are commonly absent, Parker (1923) reporting only 3 cases out of 8 with symptoms referable to the spine In a study by Meyer and Gall (1935) of 60 cases of mycosis of the spine, including 47 cases of actinomycosis, only 9 were correctly diagnosed during life, the usual diagnosis being tuberculosis, of the 60 patients, 54 died of the disease, giving a mortality of 90%

In view of the high mortality it seems worth while to publish a preliminary report on this case which has so far responded favourably to streptomycin

A woman, aged 35, was referred to medical outpatients on Dec. 20 1949, with seven months' history of pain in the back and right side, attacks of precordial pain, and loss of weight Her symptoms dated from the birth of her third child, before which she had been well In the puerperium she is reported to have had a pneumonitis In the subsequent seven months she had lost 1½ stone in weight

Examination revealed a right sided pleural effusion, and a small collection of fluid at the left base Nothing abnormal was detected in the abdomen, cardiovascular system, or central nervous system. Radiography showed a small effusion at both lung bases and mottling of the spine involving the vertebræ and adjacent ribs posteriorly of segments T5–T9

On admission to hospital on Jan 11, 1950, the patient had over the affected vertebræ posteriorly a fluctuant swelling which started to discharge through a small sinus to the left of T3 and T4 The pus contained *Staph aureus* No tubercle bacilli were found in the sputum or the urine Red cell count was 2,300,000 and white cells 22,000 per c.mm, Hb 42% Erythrocyte sedimentation rate (Westergren) was 27 mm in 1 hr Temperature was 99–101°F, pulse rate 110, and respirations 20 per minute

Progress—The sinus discharged profusely, and a second swelling appeared over the lower dorsal vertebræ On Jan. 24, a diagnosis of actinomycosis was suggested, but three negative swabs were obtained before the streptothrix was demonstrated and cultured.

Penicillin 1,000,000 units four hourly, with potassium iodide gr 20 t d.s, effected no improvement. The abscesses recurred and discharged through several sinuses The pleural effusion at the right base reappeared, and on March 14, her general condition was poor On March 15, treatment was begun with streptomycin 1 g eight-hourly, and her spine was immobilised in a plaster anterior shell The effect was dramatic by April 4 the sinuses had healed completely, the pleural effusion had resolved, her general condition was good, and radiography showed improvement in the chest and spine. She was allowed to move freely in bed after a month, and on May 2 the streptomycin was reduced to 1 g b d Streptomycin was continued until June 13

The patient was allowed up, wearing a spinal support, on June 27, and subsequently attended as an outpatient She continued to make satisfactory progress, and the spinal support was discontinued in December 1950 At that time she was fit the sinuses had remained healed, and there was no recurrence of abscess formation X-ray examination showed that the spine had not yet regained normal density, and there was narrowing of the intervertebral space between T8 and T9, there was still some opacity at the base of the right lung

I am grateful to Mr E S Brentnall for permission to publish this case

Medical Societies

BRITISH ORTHOPÆDIC ASSOCIATION

THE spring meeting was held in Cambridge on April 6 and 7, under the presidency of Mr S L HIGGS Among the subjects discussed were congenital dislocation of the hip, and the late results of disc operations

Congenital Dislocation of Hip

Mr H J SEDDON, opening a symposium on congenital dislocation of the hip, reviewed the results of treatment carried out at the Royal National Orthopædic Hospital during the first 40 years of this century Of 889 patients treated, 264 had been re examined recently by Mr G M Muller, in this series treatment had been begun 10–40 years previously Only half the patients were less than 3 years old when treatment was begun In three fifths of the cases treatment had been by manipulative reduction and immobilisation in plaster, and in half of these the results were still good In the remaining two fifths operation had been required at some stage Operative treatment had been undertaken (1) to reduce the dislocation when manipulative reduction was impossible, (2) to improve the acetabulum, (3) to correct anteversion, or (4) in cases of persistent dislocation to improve the function of the hip, usually by some form of osteotomy Open reduction had proved satisfactory in only 4 out of 20 cases Results of acetabulo plasty had been good in 22 out of 36 cases; rotation osteotomy had been satisfactory in only 3 out of 9 cases; and the results of palliative osteotomy were disappointing. Any improvement on these results must be along the following lines: (1) earlier treatment and improved methods of closed reduction; (2) earlier operation where conservative treatment was unsuccessful, and (3) improved methods for late or relapsed cases. By the plan of treatment now pursued at the hospital, closed reduction was attempted by traction on an abduction frame, with cross traction medially through a strap round the upper thigh. If reduction was not secured in four weeks open reduction was undertaken. Acetabuloplasty was undertaken when the acetabulum failed to develop after closed reduction and, if thought necessary, at the time of open reduction. Rotation osteotomy was advised if anteversion of the neck was deemed to impair stability.

Reduction and Retention.—Mr DENIS BROWNE thought that there were two elements in the production of congenital dislocation of the hip—namely, failure of development of the hip joint, and a mechanical thrust along the axis of the femur from intra uterine pressure. This thrust, acting on the limb in the flexed intra uterine position of the fœtus, caused the hip to dislocate downwards and backwards; only after birth, when the hip was extended, did the femoral head become displaced upwards. If this view was correct it was logical to reduce the dislocation by reversing the mechanism of its production. His method was to place the limb in the "intra uterine" position with the child face downwards, then to push upon the upper end of the femur in the axis of the thigh; thereby he achieved successful reduction in 95% of cases. After the primary reduction the hip was immobilised in plaster in the position of reduction for four weeks. Subsequently the reduction was retained by means of the Denis Browne splint, which allowed a wide range of abduction movement at the hip; this favoured deep engagement of the femoral head in the acetabulum. The splint was worn for up to nine months, and in about 100 cases he had not observed redislocation after it had been discarded.

Trends in Operative Treatment.—Mr DAVID TREVOR described the present practice at the Royal National Orthopædic Hospital with special reference to operative treatment, which was required in about two fifths of all cases. Of 27 recent cases of open reduction that had been reviewed, 15 had been submitted to acetabuloplasty at the same time, and 7 had had a subsequent rotation osteotomy. The oldest patient was aged 5 years 10 months. The cases in which open reduction was necessary fell into two groups: (1) those in which the femoral head was high with contracture of the soft tissues causing a narrow isthmus; and (2) those in which reduction was prevented by soft parts in and around the acetabulum. The commonest obstruction was an infolded capsule; other causes were hour glass contraction of the capsule, an infolded limbus, resistant fibrous tissue within the acetabulum, and gross enlargement of the ligamentum teres. In 5 cases redislocation had occurred after operative reduction. Of 23 cases observed for more than a year 19 were satisfactory so far. Full or nearly full movement was regained in most cases.

Acetabuloplasty was often advisable at the time of operative reduction, especially if the acetabular roof sloped steeply. An extracapsular technique, in which the acetabular roof was turned down and held by a wedge of iliac bone inserted into the site of osteotomy, was preferred. Results so far were satisfactory in 14 cases observed for one year or more, and unsatisfactory in 2. If the opportunity for acetabuloplasty was missed the femoral head might become displaced high on the ilium, and acetabuloplasty by the ordinary "shelf" procedure became impracticable. This was the type of case in which the Colonna operation was indicated. Rotation osteotomy was necessary when anteversion was sufficient to impair stability. When it was found at the time of open reduction that anteversion was excessive, rotation osteotomy was undertaken about six weeks later.

Arthroplasty for Persistent Dislocation in Adults.—Prof R MERLE D'AUBIGNÉ (Paris) described his experience of arthroplasty for persistent dislocation of the hip in adults. Operation should be undertaken only if the functional disability was severe. Of 22 patients who had been operated on 8 had had bilateral operations, making 30 hips in all. In 16 cases the interposed material had been a metal cup; in 13 an acrylic head; and in 1 the capsule. To ensure stability it was necessary to bring the head well down, to deepen the acetabulum and enlarge its upper rim by means of a screwed on graft, and to displace the trochanter downwards. After the operation the hip was immobilised in plaster in wide abduction for six weeks, after which active movements were begun; weight bearing was allowed after four months. Results in the 14 cases observed for one year or more were excellent in 4, good in 7, and poor in 3; 11 were free from significant pain.

DISCUSSION

Sir HARRY PLATT (Manchester) agreed with the plan of treatment adopted by the Royal National Orthopædic Hospital team. His experience of 645 congenital dislocations showed that a good result could be achieved by closed reduction in two thirds of all cases. He preferred reduction in one stage (by gentle manipulation) to prolonged traction on a frame. In recent years he had undertaken open reduction more often than in the past. In 88 open reductions the commonest obstacles to reduction had been abnormal attachment of the capsule, and broad ligamentum teres. He thought that the so called capsular isthmus might sometimes be only an apparent narrowing of the capsule due to incomplete filling of the joint cavity by opaque fluid.

Prof J TRUETA (Oxford) had found that the incidence of osteochondritis was 30% after reduction by traction on a frame, compared with 45% after manipulative reduction.

Mr J C SCOTT (Oxford) emphasised that traction applied to the limb of the abduction frame should be light (not more than 2 lb in each line of pull). In his series of 116 cases reduction by traction failed in only 16%.

Mr H A BRITTAIN (Norwich) preferred arthrodesis of the hip to arthroplasty in cases of persistent unilateral dislocation with arthritic symptoms in adults.

Dr P G K BENTZON (Denmark) warned against twisting the hip capsule during attempted reduction. If the capsule was twisted, reduction was obstructed and the blood supply of the femoral head might be impaired.

Mr W A LAW spoke of the need to excise the capsule completely in getting the femoral head down to the level of the acetabulum.

Mr G C GORDON (Sheffield) thought that in the ætiology of congenital dislocation of the hip rhythmic contractions of the uterus during pregnancy might be a factor, though the pressure exerted was too slight to cause dislocation of a normal hip.

Sir REGINALD WATSON JONES felt that assessment of results so early as one year after treatment was unsound. Even intermediate results could not be assessed until the age of 17 or 18 years, when growth had ceased. Anteversion was a problem that demanded careful study at all stages of treatment. If allowed to persist, it led to faulty distribution of weight in the acetabulum and predisposed to redislocation.

Late Results of Disc Operations

Mr A L EYRE BROOK (Bristol) reported the results in 117 patients observed for one to six years after operation for sciatica diagnosed as being due to a disc lesion He had studied in particular the progress of patients in whom no causative pathology had been found at operation Unless he found a definite protrusion or indisputable adhesions he regarded the exploration as negative, he did not believe in "hidden" discs or disc scars Of the 117 operations, 11 gave negative findings, adhesions had been observed in 6, and in the remainder a definite protrusion was present Of patients in whom a definite lesion was found, 86% had no more than very minor residual complaints, and of the 21 men with disc lesions who were engaged in heavy work before operation, 18 were able to return to normal work On the other hand, all except 1 of the patients in whom no lesion was found had significant residual disability at the time of examination, in the 1 exception there was complete freedom from symptoms Of the 6 patients in whom nerve root adhesions were found, 4 had moderate relief and 2 had only slight relief

Mr TREVOR thought that lumbar puncture and estimation of the protein level in the cerebrospinal fluid were advisable as a routine before exploration, and myelography should be done if lumbar puncture showed any abnormality If these precautions were neglected other lesions, such as tumour, might be missed

Professor D'AUBIGNÉ asked whether spinal fusion had been undertaken in any of the cases

Mr JOHN CHARNLEY (Manchester) felt that lesions of the intervertebral disc fell into the province of the orthopædic surgeon rather than the neurosurgeon Exploration had been negative in 16% of his patients In the earlier cases of his series he had sometimes failed to find lesions even when the straight leg raising test had been markedly positive, he considered that in such cases he had probably missed a disc protrusion at a different level. As his experience of the operation increased he found that negative explorations were less common and were usually in patients with only slight restriction of straight leg raising He held that the straight leg raising test was of the greatest value in diagnosis and assessment of the case for operation

Mr EYRE BROOK felt that whereas lumbar puncture and myelography should be undertaken in problem cases, special investigations other than plain radiography were unnecessary in the straightforward case Exploration of a disc was almost devoid of risk, and in the exceptional case where the symptoms were found to be due to a tumour no great harm was done by the exploration He did not consider that spinal fusion should be undertaken at the time of a disc exploration If significant back pain arose afterwards, this should be assessed as a separate problem in the same way as back pain from other causes He agreed with Mr Charnley that the straight leg raising test was the most significant sign

MANCHESTER MEDICAL SOCIETY

Treatment of Perforated Peptic Ulcer

AT a meeting of the section of surgery on March 13, Mr T HESLOP expressed the opinion that the conservative method undoubtedly has a place in the treatment of perforated peptic ulcer the main difficulty was in formulating guiding principles on which to base personal judgment when deciding the merits of operative or conservative treatment Most of the series hitherto described were of selected cases For the past four years parallel series had been observed at two adjacent hospitals in Salford All the cases seen at Salford Royal Hospital were treated operatively, except a few in the days before this scheme had come into operation All cases admitted to Hope Hospital had been treated conservatively under the supervision of Mr A S Bullough

During the 5 year period 1946–50 Mr Heslop and Mr C Brun had observed at Salford Royal Hospital 124 cases of perforated peptic ulcer with 11 deaths (8 8%) irrespective of the method of treatment This series included a small group of 20 unselected cases which were treated conservatively, with a mortality of 10%, subphrenic abscess occurred once but resolved after drainage Of the 104 cases treated by emergency operation, 9 (8 6%) died The peak age incidence was at 30–39 years, the sex ratio being 1 female to 20 males

The salient points about operative treatment were adequate preoperative preparation, the minimum of interference inside the abdomen, with simple closure of the perforation and no exploration of the peritoneum, maintenance of gastric suction and controlled intravenous fluid administration for 24–48 hours, and prophylactic chemotherapy and early ambulation in the absence of complications

The prognosis and mortality depended on the time-interval from the onset of perforation, the age of the patient (mortality increasing greatly over 60 years), and the situation of the ulcer Perforated gastric ulcer (17 cases) carried a mortality of 30%, perforated duodenal ulcer (85 cases) only 5% Among the 9 fatal cases, only 5 patients died from general peritonitis within four days The preponderance of peritonitis as a cause of death was striking When this was established on admission it was questionable whether operation was of any benefit, when it developed after operation on early cases it could be traced to faulty operative technique or inadequate postoperative management, and these deaths should certainly be preventable

Mr A S BULLOUGH reported his results with the conservative, or non operative, method of treatment in 102 consecutive cases of perforated peptic ulcer admitted since March, 1947, to Hope Hospital His reasons for adopting this method were the high mortality of operated cases, the occasional recovery of unoperated, desperate cases, the increasing conservatism of operative measures, the fact that at operation perforations were often found to be shut off, and the sterility of the fluid, which acted as a protective peritoneal reactive fluid

The method consisted in continuous gastric suction for several days, intravenous fluid therapy, and administration of antibiotics Patients were more comfortable than those operated on, and within a week were up and about and on light gastric diet Of the 4 females in the 102 cases, 1 died In the total series there were 8 deaths, 4 were of elderly persons admitted moribund, long perforated, and quite unfit for any operation, who died during the night following admission These cases would not have figured in the mortality statistics of any operative series The remaining 4 were late deaths (seventeen days to eight weeks), and all had unsealed perforations with fistulæ between stomach (2 cases) or duodenum (2 cases) and a cavity in the peritoneum containing gastric juice—not pus 3 of them had this cavity drained, and consequently developed an external fistula There were 93 duodenal perforations with 3 deaths, and 9 gastric perforations with 5 deaths There were 3 true subphrenic abscesses, with recovery in each after drainage

A possible criticism of the method was that it was impossible to be sure that all the cases were in fact perforations, but clinical experience, the subsequent course, X ray examination, and in some cases operation, all tended to show that they were. There was the risk of leaving unoperated some condition requiring operation 1 such case occurred On the other hand, a conservative method might conceivably preserve the lives of certain sufferers from coronary thrombosis, pneumonia, or acute pancreatitis, by avoiding a dangerous operation

Reviews of Books

The Principles of Pathology

R A WILLIS, M D , F R C P , professor of pathology in the University of Leeds London Butterworth 1950 Pp 667 50*s*

PROFESSOR WILLIS presents the subject of pathology in an unconventional way he will have none of the usual subdivision into general and special, but aims at a logical sequence, having in mind always the student who has just completed his studies in anatomy and physiology Pathology, he tells him, is extended anatomy and physiology it is the study of all that the body and its tissues can be and do under all possible abnormal conditions Therefore, he deals first with repair and regeneration, processes which the doctor will constantly observe throughout his professional career Then comes a series of chapters on inflammation and the sequelæ in particular sites, followed by chapters on bacteria, viruses, and parasites and the diseases which they produce, on immunity and diseases due to sensitisation, foreign bodies and poisons, and on disturbances of nutrition, metabolism, circulation, and hæmopoiesis A section on neoplasms, which is a summary of his *Pathology of Tumours*, is notably well presented, though not everyone will agree that myeloid and lymphoid leukæmias are best described under the heading of neoplasms of the hæmopoietic tissues Endocrine disturbances and obstruction and dilatation of hollow organs, so often produced by tumour growth, follow naturally, and the last chapter deals with the whole range of antenatal pathology

This is a pleasant alternative and an important supplement to the more conventional textbook of pathology Professor Willis's style is frank and critical and he has plenty of scope to expose misconceptions He makes full use of hand lens illustrations A glossary of Greek and Latin words, and good advice on the observing and recording of facts, and on the use and abuse of eponyms, are given in appendices A short account of the great pathologists supplements the historical details included in the text, some of which are refreshing and happily chosen

Vitamins and Hormones

Vol III Editors ROBERT S HARRIS, professor of biochemistry of nutrition, Massachusetts Institute of Technology, Cambridge, Mass , KENNETH V THIMANN, professor of plant physiology, Harvard University, Cambridge, Mass New York Academic Press 1950 Pp 342 $6 80

THERE are eight reviews in this, our old friend of eight years' standing , and the publishers have managed to do the job at less than their price of two or three years ago—a most uncommon feat An article on the " animal protein factor " and B_{12} in nutrition, by L M and T F Zucker makes good reading, but our knowledge about B_{12} has been expanding so rapidly in the last few years that readers must be prepared to write the last few pages for themselves Henry Sherman, in a study of the relationship of pyridoxine to fat metabolism, raises a number of interesting questions without being able to give a final answer to any of them Those who are unhappy about the existence or physiological importance of the " antistiffness " factor for guineapigs, or about " relaxin " will find W J van Wagtendonk and R Wulzen, and F L Hisaw and M X Zarrow highly informative about these substances Both pairs of authors believe that pure chemical compounds are responsible for the effects which they themselves have done so much to describe , but neither the vitamin nor the hormone has yet been isolated in identifiable form Now that sugar cane juice has been found to be so rich in the " antistiffness " factor, however, there is every reason for hope that the biochemists will soon have this vitamin in the bag H K Mitchell contributes a paper on vitamins and metabolism in neurospora, and R Courrier, the French pathologist, writes on the interactions of œstrogens and progesterone, which he has been studying since 1926 R L Stehle has completed his review of the physiological actions of the posterior lobe of the pituitary Those who are anxious to know anything about the configuration of the sterols may be recommended to read the last art by C W Shoppee, now working at the Universit Wales

Some of these reviews are, naturally, better t others, but most of them begin at the beginning of t subject, and outline its development , and this is inv able for the outsider who wants to get a grasp of it is seldom able to do as much from a volume review recent works

The Life of Dr John Radcliffe, 1652-1714

CAMPBELL R HONE, Hon Fellow of Wadham Coll Oxford London Faber & Faber 1950 Pp 149

THE Bishop of Wakefield has done the coming histo service by writing this important biography Radc was a Yorkshire man of middle class, fearless, ruthl and shrewd, in admirable control of his temper, but us language which bit hard when he was intolerably p voked Common sense combined with fearlessness dealing with patients of all kinds marked his long car and his generosity—so conspicuous in the West Rid of his county—was an instinct That impulse in midd class folk which impels them to seek some gentle or e noble forebear induced Radcliffe to claim Derwentwa as his own , and this claim to the best blood in Riding, which still flows in the Rudding Park fami was seemingly tolerated For the medical reader t volume deserves a niche near Paget's *Stephen and Bish Paget* and Harvey Cushing's *Osler*, where they and it m be read and re-read with profit and pleasure

General Clinical Counseling in Educational Institut

MILTON E HAHN, professor of psychology, Universi of California, Los Angeles, MALCOLM S MACLEA professor of higher education at the university London McGraw Hill 1950 Pp 375 30*s*

UNIVERSITY students sometimes seek, and often need, guidance about their academic troubles an decisions It is unlikely that any single person can gi all such guidance as a student may require in the Unite States, however, a profession has developed, and th " counselor " is trained to help students in all the educational and vocational difficulties " Clinical coun seling " is defined by Professor Hahn and Professo MacLean as " a process which takes place in a one to-on relationship between an individual troubled by person problems with which he has been unable to cope alon and a professional personnel worker whose training an experience have qualified him to aid others to reac solutions to various types of personal difficulties " must " be concerned with the total dynamic adaptatio of the individual " These phrases have a familiar rin " counseling " is the little sister of psychotherapy and this book she shows one of the family failings, for muc flabby writing is required to express a commonplac opinion The case for expanding advisory facilities fo students, which has much to support it, is not helped b this book

---

A Calendar of Country Receipts (*London Faber* Faber Pp 192 16*s*)—Miss Nell Heaton not content wi her victories in the realms of straight cooking, has invad another that of the old time country lore of the still roo and herb garden It is a fascinating place, a land of rever and nostalgia Miss Heaton, however, does not desp modern short cuts to the results of our forebears In oth words, the book is not only redolent of old housewifery a medical lore, but practical And Leonard Huskinson pictures add to its vivacity

Das Strichbild *Zum Form und Stoffproblem in d Psychologie der Handschrift* (Stuttgart Thieme 195 Pp 60 DM 6 60)—Dr R Pophal, who is professor graphology at the University of Hamburg, has been workin at the criminological institute in that city on the analys of strokes in handwriting as indices to personality Thoug no doubt experienced and skilful in his interpretations, h fails to give proof of the correctness of his apparently intuitiv readings, and he makes the reader's task needlessly difficu by his style The technical details he gives will be of intere to graphologists, but the psychologists and physicians f whom he has also intended the book are better served b more humdrum studies

THE LANCET

Cortisone and Infection

How safe is treatment with 'Cortisone' or A C T.H ? dministration of these hormones is almost always tended by some signs of hyperadrenalism, and he danger of hyperadrenalism, as CUSHING [1] pointed ut, is increased susceptibility to infection In eating the pale rheumatic child with some disorder of is antibody responses, shall we gain only a fit-looking hild with no defences against infection, who makes is symptomless way to death from septicæmia ? his danger has been much in the minds of research-orkers, indeed, only two years after the discovery f the therapeutic action of cortisone, KASS and INLAND [2] can quote references to 123 reports dealing ith its influence on infection and immunity

Clearly these hormones may influence the body's eactions to infection at every stage from entry of the nvading organism to repair of the tissue damage he evidence is based mostly on experimental work with comparatively large doses, and there have been few satisfactory accounts of serious septic complications in man. Where A.C.T H has been used to treat bacterial pneumonias in man,[3] clinical remission has been prompt In one case, after 24 hours' treatment fever and pleural pain and physical signs disappeared, the patient felt well, and appetite returned, but at the same time both sputum and blood contained many type-8 pneumococci A.C T.H. was continued, and fever did not return, but not until the fourth day did the blood become sterile Nevertheless there seemed to be no interference with antibody response, specific antibodies appeared on the eighth day In general, the signs of illness in patients with pneumococcal pneumonia were suppressed by A C T.H., but it seemed that development of the infection was uninfluenced. With experimental pneumococcal infection, cortisone influences the outcome unfavourably, as Dr WHITE and Dr MARSHALL [4] showed in their report last week in these columns Similarly D'ARCY HART and REES [5] found that tuberculous infection of mice was enhanced by cortisone In man symptoms of tuberculosis are promptly alleviated although the disease itself is unaffected or aggravated, judging by radiographic and sputum examinations [6] This warns us of a possible future danger now that both B C G vaccination and cortisone therapy are becoming more common obviously cortisone should not be given to B C G-inoculated children until further work has shown that this is safe As regards group-A streptococcal infections, HAHN and his associates [7] have established that in man these are not benefited by cortisone in doses of 100 mg daily, in fact the duration of fever was increased, while other symptoms, such as malaise, sore throat, and headache, were found equally among treated and control groups Cortisone had an even more unfavourable effect on hæmolytic streptococcal infection in mice [8] and in rabbits [9] Likewise with malaria, in man administration of A.C T.H. has little adverse effect except to increase the peripheral blood parasite count, but in *monkeys it may precipitate* blackwater fever [10] In virus infections in man, such as poliomyelitis [11] and virus pneumonia,[3] the course of the disease is not shortened In mice and ferrets with virus-A influenza, A.C T H. increases the mortality-rate without affecting the lung changes or antibody responses [12] In some animal experiments the doses, weight for weight, exceed those given in man, and overdosage must account for some of the experimental findings

A similar conflict between experimental and clinical results has arisen in the investigation of wound healing Cortisone or A C T.H, in doses equivalent to 100–500 mg per day in man, delays or inhibits the healing of wounds in rabbits [13], but when patients with rheumatoid arthritis are maintained in clinical remission by small doses of cortisone, such as 100 mg or less per day, there may be no apparent interference with healing,[14] or healing may be speeded.[15] It all seems to be a matter of dosage, or rather of the degree of hyperadrenalism produced.[16] Most reports agree that mild hyperadrenalism is inevitable, but the relative absence of well documented descriptions of serious infection complicating treatment does not suggest that this is such a serious danger as animal experiments seem to indicate Certain precautions may help to avoid trouble Patients receiving these hormones should be repeatedly examined, and absence of symptoms should not be taken as proof of well-being, since an abscess may only declare itself as a painless lump It would be wise not to allow patients to give their own injections, unless their facilities for, and knowledge of, sterile precautions are good Patients on doses that produce well-marked hyperadrenalism should receive prophylactic injections of antibiotics, in any case we should not give such high doses for long, but should be content, as HENCH has observed, with the partial control of symptoms from smaller dosage Now that cortisone made up in tablets for oral administration has proved effective, there may be a greater danger of infections because of the greater ease of self-medication In those diseases, such as disseminated lupus erythematosus, Hodgkin's disease, and leukæmia, where granulopenia is known to occur, the total and differential white cell count must be investigated regularly, and blood cultures taken, if there is any reason to suspect bacteræmia The differential diagnosis between rheumatic fever and subacute bacterial endocarditis is sometimes difficult, and obviously the danger of wrongly treating the latter with cortisone must be borne in mind, particularly in older patients with established valvular lesions A golden rule would be "wherever there is doubt, treat first with antibiotics" If the patient has rheumatic fever he will not respond, and cortisone can then be given, but if cortisone is given first he may respond, whatever the underlying cause, and much valuable time may be lost, or the patient may die from uncontrolled septicæmia if in fact he has bacterial endocarditis Similarly the unwary may confuse pyogenic or tuberculous arthritis with gout or other non infective arthritis, again, the rule must be to give antibiotics first wherever there is doubt When antibiotics are given with cortisone, it would appear that large doses are necessary With successful chemotherapy the reproduction rate of the invading organisms is reduced below the rate at which the natural defences of the body can deal with them, and cortisone impairs these defences, tipping the balance back in favour of the organism Antibiotics may thus become relatively ineffective, and there is some evidence, both clinical[17] and experimental,[18] that this does take place

On the whole it would seem that uncontrolled infection is a complication of overdosage with cortisone, and that with common sense rules about diagnosis, and vigorous chemotherapy where necessary, cortisone is safe enough and well worth what risk it entails

Neurosurgery and Muscle Function

MOST of the operations performed by the neurosurgeon are undertaken to prevent, or to check, disorganisation of neural function produced by structures extraneous to the central nervous system itself—by tumour, abscess, foreign body, scar, or hæmatoma In a proportion, however, the aim is to modify deranged neural function in such a way as to bring it nearer normal Unfortunately, except in the restoration of continuity of peripheral nerves, no reconstruction of neural pathways is possible, and, to an already damaged nervous system, surgery can contribute only another lesion None the less, such treatment has certain theoretical possibilities If a pathological lesion at a certain "level" has released the activity of lower centres, it is clearly possible by suitable operative procedures to diminish, or even to abolish, the abnormal activity Thus involuntary movements may be stilled, or rigidity replaced by flaccidity Where abnormal activity is confined to certain muscle groups, the operation may be so designed that these alone are affected Such surgery, however, does no more than relieve symptoms, and it may have undesirable consequences For the normal performance of willed movement the mechanisms subserving involuntary activity must be normal, surgery, even if confined to these mechanisms, must therefore at the same time impair voluntary movement In cases of infantile cerebral palsy surgery has an even more serious disadvantage in that it also impairs *potentiality* for voluntary movement Further, apart from these motor effects, sensory and autonomic changes result from some of the procedures used Hence, before deciding to operate, the harmful possibilities of the proposed operation must be weighed very carefully against the expected benefits

In view of these facts, it was useful to hear the experiences contributed by neurosurgeons to a discussion by the neurological section of the Royal Society of Medicine on April 5 Dealing with spinal cord lesions, Mr HARVEY JACKSON pointed out that recovery of function is often substantial where interruption of the cord is incomplete, so in such cases resort to surgery is not considered Where the patient is helpless, however, with a paraplegia in flexion and associated "mass reflexes" (paroxysmal sweating with flexion spasms of the affected parts, bladder contraction, involuntary defæcation, &c), section of the anterior nerve roots from the 10th or 11th dorsal to the 1st sacral may be of great benefit The spastic paralysis is replaced by flaccidity, and "mass reflexes" are abolished, the patient is made much more comfortable, nursing is facilitated, and, if the lesion is below the outflow to the arms, progression with the aid of suitable appliances may be rendered possible Later in the meeting Dr L GUTTMAN emphasised the necessity of severing the nerves to spastic abdominal muscles as well as to the legs if satisfactory results are to be obtained, though such an operation is a formidable undertaking in a patient in whom vasomotor control is poor For complete transverse cord lesions he recommended the intrathecal injection of alcohol, despite the atony of the bladder induced thereby This is a method by which flaccid paralysis may be produced when operation is contra-indicated by the presence of bedsores Posterior root section was not recommended.

Several speakers referred to the treatment of spasmodic torticollis, but none claimed satisfactory results Mr HARVEY JACKSON reminded his audience that the spasms may be abolished after prefrontal leucotomy, but held that the cost in personality change is too high to justify its adoption He quoted JAMES COLLIER's view that spasms would continue in this condition even if, after operation, this was the only contractile structure left in the neck!

Turning to surgery in parkinsonism, Mr JACKSON thought that lateral cordotomy, by which the indirect pyramidal tract is severed for the relief of tremor, should be reserved for young patients in whom the tremor is strictly unilateral The paralysis produced recedes after operation, but a certain amount of permanent spasticity remains Tremor may return to some extent as voluntary power recovers The incision he uses is similar to that originally advocated by PUTNAM.[1] Though results vary from patient to patient, the method has the advantage that the crossed spinothalamic tract is avoided, and it does not cause the permanent loss of pain and temperature sensation on the contralateral side of the body which is seen if the incision is carried further forwards In the mind of the meeting there seemed to be little doubt that spinal cordotomy is the most satisfactory operation for the relief of parkinsonian tremor ablation of areas of the cerebral cortex may be followed by epilepsy, and the operative mortality from interruption of the pyramidal fibres in the internal capsule is high It is clear, therefore, that rgery has but a very limited place in the treatment parkinsonian tremor, and no satisfactory surgical ethod of reducing rigidity has so far been devised. t present, indeed, direct operative approach to oblems of abnormal neural function has only a nall, though useful, application. No doubt this will e extended.

Anæmia in Pregnancy

EXPERIENCE in outpatient and antenatal clinics uggests that the incidence of anæmia in pregnancy s increasing Today most women in this country ust continue their housework and shopping up o the latest possible moment, and anæmia, even if light, makes it more difficult for the woman to carry on, and also slows postpartum recovery Yet this anæmia is always treatable, and is nearly always preventable, increased vigilance would obviate much unnecessary debility in pregnancy and the puerperium.

It is not easy to discover the incidence of anæmia in pregnancy In 1944 FULLERTON and his colleagues[1] in Aberdeen put the figure at only 4%, at the other end of the scale, from the U S.A. comes an estimate[2] that 54% of women attending an outpatient clinic in Michigan were anæmic, 27% had iron deficiency anæmia, 15% nutritional anæmia, and 12% both forms In a more recent survey SCOTT and GOVAN[3] found that 4595 women in Glasgow had an incidence of 17 6% at their first attendance, and a further 2 5% became anæmic during the pregnancy A serious difficulty in deciding whether anæmia is present is occasioned by the normal fall in the red cell count and the hæmoglobin level that begins after the first month of pregnancy and reaches a maximum at about the sixth month The fall is caused by the increase in blood and plasma volume that takes place at this time, there is some increase in the red-cell mass—estimated by ROSCOE and DONALDSON[4] at 12%—but the increase in plasma-volume is of the order of 25% It might be possible to estimate how far the red cell count and hæmoglobin level could be expected to fall, and low normal" limits of about 4,000,000 red cells per c mm and 10 5 g hæmoglobin per 100 ml. have been suggested, only patients with counts below these levels being counted as "anæmic' But TYSOE and LOWENSTEIN,[5] who have re-investigated this problem, found great variations from case to case, and they finally admitted the impossibility of predicting normal values for any given patient at any stage of pregnancy They did, however notice that, whatever the hæmoglobin level, the concentration of hæmoglobin in the red cells remained normal this concentration is conveniently measured by the ratio of the hæmoglobin to the packed cell volume (hæmatocrit), the resulting figure being the mean corpuscular hæmoglobin concentration (M.C.H C) In iron deficiency anæmia—the commonest anæmia of pregnancy in this country—the M.C H C is significantly reduced, and therefore estimation of the ratio will discover this anæmia whatever the blood dilution. The M.C.H.C will not detect the megaloblastic types of anæmia, but these are always severe enough to be obvious Unfortunately no British survey has yet been reported on these lines

In Britain iron-deficiency anæmia accounts for perhaps 95% of the cases of pregnancy anæmia, megaloblastic anæmia is relatively very rare, nutritional anæmia, though difficult to assess, probably arises only in combination with iron deficiency The problem, therefore, is mainly to prevent, detect, and treat iron-deficiency anæmia

During pregnancy the body's demands for iron are substantial the fœtus is supposed to need 375 mg, iron is needed, too, for the increase in the red cell mass and in other tissues, and to replace that lost in the blood at labour There is, it is true, some saving from the absence of menstruation, but the iron needs of a normal pregnancy are reputed to exceed by 2–3 times the loss from menstruation over the nine months McCANCE and WIDDOWSON[6] state that the amount of iron needed by the pregnant woman is about 16–20 mg daily In 1947 BRANSBY and MAGEE[7] showed that the British diet then provided about 11 mg of iron daily Since 1947 the position, so far as iron-containing foods is concerned, has got worse Meat is normally our richest source of iron, if the housewife lays out her money to best advantage she may get as much as 10 oz of lean 'stewing steak," but this will provide her with only about 15 mg of iron for a week. Where she is to get her iron ration for the other six days is not very clear Unrationed meats, some fish, peas and lentils, and wholemeal bread, all contain enough iron to contribute to the store, eggs would be useful, but in winter at any rate, these are too few to count McCANCE and WIDDOWSON's tables show that the only foods that approach meat in iron content are such things as sardines, the famous spinach, and some breakfast cereals (but not oatmeal porridge), boiled mussels contain three times as much iron as an equal weight of meat, and boiled winkles four times as much, but these can hardly become the daily portion for expectant mothers SCOTT and GOVAN[3] estimated that the diet of their Glasgow mothers contained as much as 16 67 mg of iron daily, but they did not give details, and in view of other estimates this seems exceptional It is reasonably clear that in this country most expectant mothers can obtain at best only the bare minimum of food iron needed Under these conditions, and under better conditions too, a woman depends on her iron stores to provide the iron required to meet the demands of pregnancy These stores may be diminished by previous ill health (particularly gastro intestinal disturbances), by previous poor diet, by pregnancies following too closely on one another, and by previous excessive menstruation In other words, the incidence of anæmia in pregnancy depends as much on the mother s health and diet in the months preceding the pregnancy as on what happens during the pregnancy itself.

Prevention of anæmia therefore depends, partly at least, on an adequate diet before and during pregnancy An American authority[2] puts it succinctly if every woman could have 1 quart of milk, 4 oz of meat, and 1 egg, and was given gr 15 of ferrous sulphate daily during the pregnancy, most cases of anæmia—of all types—would be prevented He was surprised that even in a rich farming countryside many women failed to obtain this reasonable minimum In this country, under present conditions, the milk can be obtained , but not the rest—except for specially favoured people Ferrous sulphate is distributed in tablet form at many antenatal clinics, but this is not entirely successful for several reasons Firstly, the tablets often cause gastric disturbance, and less often diarrhœa , the women then accept but do not take the tablets This difficulty could be largely obviated by the routine use of enteric coated tablets, which are not expensive to prepare in bulk A second cause is more complicated We have learnt that the amount of iron that can get across the intestinal barrier in a given time is limited—doses in excess of gr 30 daily are excreted **Hahn** and his co-workers,[8] using radioactive iron as a tracer, have lately confirmed that in pregnant women the percentage absorption of iron from an oral dose of ferrous sulphate falls off with big doses The best proportional absorption is obtained with a dose as small as 9 mg Fe (about gr $^1/_2$ of desiccated ferrous sulphate) , increasing the dose to 120 mg Fe (gr 6 ferrous sulphate) only doubled the amount of iron actually absorbed They also found that absorption was maximal towards the end of pregnancy with a dose of 9 mg Fe only 10% was absorbed up to the fifteenth week , between the fifteenth and twenty-fifth weeks the figure rose to 35% , and after the thirtieth week to 40% They conclude that the indiscriminate distribution of iron tablets to pregnant women is of doubtful value The patients studied by **Hahn** and his colleagues were not, however, anæmic , in anæmic women the iron absorption can be expected to be much increased, roughly in proportion to the fall in hæmoglobin level But in anæmic women another difficulty arises if the iron stores are empty, such iron as is absorbed goes first to these stores, and only when a certain level is reached is the iron released to be combined into hæmoglobin Women whose iron stores are depleted, from any of the causes already named, will take the pills but may still become anæmic , and we have no way of detecting such cases

Iron deficiency anæmia is usually best treated by giving about gr 25 of ferrous sulphate daily by mouth, preferably in enteric coated tablets For those who do not respond to iron by mouth, or whose anæmia is detected only late in pregnancy, intravenous iron has proved a great success, and its use has almost completely removed the need for blood transfusion **Scott** and **Govan**[9] found that of their anæmic patients 22% were resistant to iron by mouth but responded well to intravenous administration of 100 mg of elemental iron daily They noted, however, that 34 5% of moderate and 40% of severe cases showed a delayed response to intravenous iron, which they attributed to lack of protein in the diet In the U S A **Kartchner** and **Holmstrom**[10] also report good results with intravenous iron in pregnancy anæmia, and emphasise its value when gastro intestinal upsets prevent effective oral administration. The megaloblastic, or "pernicious," anæmia of pregnancy presents as a severe anæmia with hæmoglobin commonly reduced below 7 g per 100 ml., the cause is unknown, but it does not seem to appear when nutrition is adequate Marrow-puncture reveals the diagnosis at once Treatment is by folic acid, parenterally if necessary at first in a dose of 100–150 mg , and then 20 mg daily by mouth Vitamin B_{12} is here of no value

Much more can be done to detect and treat pregnancy anæmia in the early stages It is not possible for every patient attending an antenatal clinic to have her hæmoglobin level and the M C H C estimated, this would put too great a strain on an already overburdened pathological service But if the obstetrician, and the midwife, could train themselves to look regularly at the conjunctivæ of their charges, they could select for investigation those that appeared unduly pale , and if anæmia were discovered, treatment should be started then and there The provision of proper nutrition in pregnancy is outside the doctor's control , but he can at least show how to make the best of what food there is

Annotations

VIOMYCIN

A NEW antibiotic which may prove useful in the treatment of tuberculosis was discovered last year in the U S.A , and was named ' Viomycin ' This is obtained from two strains of streptomyces—*S puniceus*, and *S floridæ* It is a strong organic base containing guanidine and a peptide linkage, and forms a sulphate which is stable in solutions of pH 5–6 at room temperature , little else is known about its chemistry It is bacteriostatic rather than bactericidal, and resembles streptomycin in that mycobacteria readily become resistant to it , tests show that the H37Rv strain of *Mycobacterium tuberculosis* becomes resistant to both drugs at about the same rate A strain of tubercle bacilli highly resistant to viomycin in vitro can be produced by serial transfer of the culture through eight solutions containing increasing concentrations of the drug Viomycin is, however, active against strains of tubercle bacilli which are resistant to streptomycin Unlike streptomycin it has relatively little activity against gram negative organisms in vitro though experimentally, it has proved more effective in vivo In vitro most strains of *Myco tuberculosis* are inhibited by concentrations of 1–5 µg per ml , and pneumococci, streptococci, and staphylococci are inhibited by concentrations of 40–100 µg per ml

Three different groups of workers[1] have shown that viomycin is as effective as streptomycin against tuberculosis in mice and guineapigs infected with the H37Rv strain of human tubercle bacillus , a daily dose of 0 5 mg significantly increases both the survival time and the survival rate of infected animals A daily intramuscular dose of viomycin 40 mg was as effective as streptomycin 100 mg These two antibiotics can be given together , they are not antagonistic but neither are they synergistic Viomycin is only slightly toxic to animals, and no ill effects were produced by giving rats subcutaneous injections of 50–100 mg per kg body weight daily for six weeks The same dosage was well tolerated by dogs for five months, but in cats it caused disturbances of posture and gait Viomycin can be given intramuscularly or intravenously without local irritation, and it can also be given by mouth In man, however, it seems to have more side effects than streptomycin Werner and his colleagues[2] gave daily intramuscular doses of 30–70 mg per kg body weight to 10 tuberculous patients The drug caused renal irritation in all, abnormalities of the serum electrolytes in 5, elevation of the blood urea in 4, impairment of vestibular function and partial deafness in 2, and hyper sensitivity reactions in 3 The disturbances in the serum electrolytes included hypokalæmia, hypocalcæmia, hypochloræmia, and hypophosphatæmia, and an increase in the carbon dioxide combining power of the blood These changes were prevented or reversed by replacing the deficient ions In vitro the strains of *Myco tuberculosis* isolated from these patients before treatment were sensitive to viomycin 6 2–12 5 µg per ml., but after 60–70 days' treatment resistance increased 8–16 times, developing in the same way as resistance to streptomycin This investigation was made to test the toxicity of viomycin and its ability to produce drug resistance rather than to test its therapeutic value A favourable response was observed, however, in some of the patients, this may be of some significance because 8 of the 10 patients had failed to respond previously to streptomycin and para aminosalicylic acid (P A S) and were unsuitable for artificial pneumothorax or other surgical treatment Werner and his colleagues, though hesitating to make any therapeutic claim for viomycin at this stage, believe that the toxic effects are not serious enough to preclude its use in man, and that it could be used for treatment provided that more extensive trials show that it is as effective as streptomycin or P A S It has the advantage of being effective against strains which are resistant to streptomycin, and the development of resistance may be prevented by intermittent therapy, which has proved effective with streptomycin,[3] and with a combination of streptomycin and P A S[4] Conceivably combined intermittent treatment with viomycin, streptomycin, and P A S might prevent the appearance of resistance to any one of them

LIQUORICE IN ADDISON'S DISEASE

OUR readers will recall that last year Professor Borst and his colleagues[5] showed that liquorice extract taken by mouth had effects qualitatively similar to those of injected deoxycortone and of adrenocorticotropic hormone (A C T.H), but that the similarity did not extend to the effect of A C T H on rheumatoid arthritis or of deoxycortone on Addison's disease These observations led Groen and his co-workers[6] to repeat Borst's observations in another case of Addison's disease Unlike Borst they found that liquorice was effective, after preliminary treatment with deoxycortone the disease was controlled by liquorice extract 15 g per day, and withholding the extract caused return of symptoms and the characteristic blood changes A further course of treatment with liquorice extract produced clinical remission and reversal of the blood changes, and the patient was finally stabilised on liquorice extract 20 g per day with a sodium chloride intake of 10 g per day These workers were unable to account for the failure in the case described by Borst, and Borst himself saw this second patient and was convinced of the benefit obtained Another patient with Addison's disease was treated by Groen et al with a crude preparation of one of the main ingredients of liquorice a daily dose by mouth of 3 3 g of ammonium glycyrrhizinate was given with success to this patient, who had previously been treated with deoxycortone 2 5 mg daily It is interesting to note that glycyrrhizonic acid contains glucuronic acid, and also glycyrrhetinic acid which has a formula closely resembling the group of steroid hormones to which deoxycortone belongs If in fact liquorice proves efficacious in some cases of Addison's disease the economic gain would be substantial, for deoxycortone costs 7*d* per mg, whereas powdered liquorice root costs 3*d* per oz

SOCIAL CASE-WORK

NEARLY three years since the coming into force of the National Health Service Act there are still doctors and others in the hospital services who cannot understand why almoners are necessary now that financial assessment of patients is not required An even larger number believe that an almoner's duties today should consist mainly in arranging for convalescence, for home helps, for splints or appliances—in fact for all those welfare services inside and outside the hospital that are so important for the patient's recovery Local health authorities certainly seem to hold this view, and arrangements and arguments about aftercare are apt to deal with the whole matter at a superficial level Actually medicosocial work, or social case work, in its application to medical problems goes deeper than this, and elsewhere in this issue Miss Margaret O'Farrell propounds a thesis that will come as a surprise to many She argues that instead of a medical or nursing training being an advantage for the medicosocial worker, it may even be a handicap, for it tends to induce an approach that prejudices the relationship of patient and almoner from the first

Miss O'Farrell says that in the early stages of the training of the almoner she should not be in a hospital, and this point of view goes some way to explain why the Institute of Almoners, whose latest report we reviewed on April 7, has not always been willing to accept for training those who have worked in hospitals as welfare clerks The recent announcement that the institute is opening its register to certain "unqualified" almoners is therefore all the more praiseworthy because it is accepting a risk that some thus recognised will never do more than welfare work at a superficial level. Of course such welfare work must be done, and it is better done by those trained in the understanding of human relationships, so the almoner's department of a hospital will remain, it is hoped, the spot where doctors and patients alike can take their troubles It is clear from articles and correspondence in the *Almoner* last year that the almoning profession is still working out a satisfactory compromise between the demands for such welfare work and the deeper need of patients to make the adjustments in their lives which their illnesses have made essential One immediate difficulty arises—namely, the shortage of almoners, to which the Cope Committee has again drawn attention, and the need to spread the supply over the whole country It is obvious that the welfare side of the work can be done more rapidly, with more "items of service" by each worker than is possible with the careful establishment, in a series of interviews, of a personal relationship that will enable the patient to face his or her situation and see clearly what action is involved Much of this work is psychological in character, and almoners are being criticised for attempting too much at this level, to the neglect of the superficial help over more material things on which the almoners' profession built up its reputation and which today is being to some extent relegated to untrained assistants

Inevitably the question is being asked "can we afford it ?" A possible answer is that hospital physician and surgeons who appreciate the social implications o disease are more and more demanding the type of case

work that only the trained social worker can do The question whether or not the health visitor can be regarded as a medical social worker in this respect is highly controversial Recent correspondence in the *Times*, following the criticism that a nursing officer at the London County Council divisional health office might not necessarily be the best person for liaison between hospital almoners and the various agencies in the field of aftercare, showed an interesting difference of opinion On the one hand representatives of the health visitors protested at what was regarded as a slur on public health nursing staff, and on the other hand supporters of the school care committee work claimed with some pride that the care committee organisers were trained social workers There is some danger in recent developments well illustrated in *The Consul*—a modern Italian opera dealing with another set of human problems The pathetic song in the consul's office, with the theme "My name is a number, my story a case," indicates what can happen when the personal relationship of social worker with patient is achieved only through a medium of files and correspondence Social case work in a medical setting seeks to avoid this, and Miss O'Farrell's article is bound to set many thinking afresh

DIAGNOSTIC AIDS IN GENERAL PRACTICE

ON April 18 the general practice section of the Royal Society of Medicine heard an account of the diagnostic unit Dr John Hunt has established in his practice in London On his return from the war Dr Hunt decided to see his patients in a building separate from his residence Besides the rooms he needed for consulting rooms and waiting rooms, and a secretary's office, the house he chose contained a tiled basement room formerly used as a kitchen This he adapted as a laboratory, which he put in charge of a full time technician recently demobilised from the R A F medical services From the beginning he found this arrangement so satisfactory and so helpful that, when a chance came to secure adjacent mews premises, he took the further step of installing X ray and electrocardiographic apparatus under the care of a qualified radiographer He has now had this combined diagnostic unit in full use for more than three years The types of investigation undertaken include all the routine urine tests, blood counts, serum tests, and simple bacteriology the more involved bacteriology, and all histology are sent elsewhere In the same way, the X ray unit undertakes radiography of all bones and joints (including fractures), teeth and sinuses, and chests, but not such investigations as intravenous pyelography, or barium meals or enemas The immediate interpretation of the findings in both laboratory and X ray room is made by Dr Hunt with the help of the technicians, but a consultant pathologist sees the report on each test, and a consultant radiologist sees each X ray film before any decision is deemed final

In the past three years, Dr Hunt said, rather more than 5000 patients have passed through his hands—some for casual consultation, others with long illnesses For these patients over 7000 laboratory tests have been made, and 1400 X ray examinations Analysis of the cases shows that the range of work undertaken has not differed materially from that encountered in a typical general practice, but the proportion of tests is much higher than most general practitioners demand Dr Hunt would be the first to admit that the results obtained often do no more than confirm a diagnosis already made, but he feels that the satisfaction of confirming the diagnosis, or occasionally of upsetting it, justifies the performance of these tests His patients seem to share his views, for Dr Hunt is engaged solely in private practice, and each of the tests is paid for by his patients—and willingly paid for, we are informed—for the sake of a speedier and accurate diagnosis, and in preference to waiting for similar tests to be performed without charge through National Health Service arrangements Dr Hunt realises that, because of their expense, facilities such as he enjoys could not be provided by doctors themselves for their N H S patients, but he believes there is scope for the public provision of units such as his to help groups of practitioners, or, failing this, for giving more practitioners direct access to the diagnostic departments of hospitals

The discussion that followed showed what great importance the efficient modern practitioner attaches to obtaining proper pathological and radiological help, and showed also that under present conditions direct access by the practitioner to hospital departments is the means most favoured Several speakers spoke of satisfactory arrangements in their own hospital areas, and none doubted that extension of this system of direct access is both desirable and practicable Experience, it was said, has proved that practitioners do not abuse the right to go direct to the pathological and radiological departments and to use the specialists there as consultants. In the end, the load placed on the hospitals—both on the outpatient and the diagnostic departments—is less than if all patients have to be seen by a consultant physician or surgeon before tests are undertaken Wherever possible, it was felt, the practitioner should make a habit of visiting the hospital and consulting with the radiologist or pathologist about their findings Where this is regularly done, not only does he get the maximum help, but consultant practitioner relationships develop that are a source of mutual satisfaction

PENICILLIN IN EMPYEMA THORACIS

PENICILLIN has revolutionised the treatment and prognosis of pulmonary suppuration Combined with postural drainage, it has reduced to a rarity the operation of external drainage of lung abscess, for the few cases which do not respond the surgeon now prefers lobectomy Penicillin is similarly useful in the management of suppurative bronchitis and bronchiectasis

In empyema, however, the value of intrapleural penicillin is still disputed The objections to this treatment centre on the mechanical complications of rigid pleura and fibrinous deposits which follow delay in the evacuation of pus, preventing complete re expansion of the lung once adequate drainage has been established The early work by Roberts and others[1] showed the dangers of continuing too long with repeated aspiration and penicillin replacement, and Brock[2] has suggested that many of the cures so obtained are really cures of early pleural effusion While in no way underrating this criticism of "conservative" treatment, Dr Asher and Dr Davies, whose article appears on an earlier page, have put this method of treatment once more to the test They have obtained gratifying results in twelve consecutive cases of empyema treated by aspiration with replacement by 500,000 units of penicillin every 1–3 days, combined with systemic administration of the drug Pus disappeared after an average of 40 days, and the average length of stay in hospital was $7^1/_2$ weeks Full re expansion of the lung was achieved in all cases, and residual bronchiectasis was found in 1 only Progress has been followed for 16–33 months

Admittedly treatment by repeated aspiration takes time, but probably no longer than surgical drainage, and in skilled hands it is no more irksome to the patient It can be regarded as a permissible method of treatment in the early stages of the disease and when the exudate is small, provided the physician is alive to the need for surgical intervention where fibrin forms quickly or the condition threatens to become chronic Failures from this cause may become fewer as experience with fibrinolytic agents widens

SOCIAL CASE-WORK IN A MEDICAL SETTING

MARGARET B O'FARRELL
B.A. Oxfd, A.M.I.A

RESEARCH ASSISTANT, DEPARTMENT OF SOCIAL STUDIES
UNIVERSITY COLLEGE HULL

SOME years ago an almoner in an outpatient clinic at the end of the day found an elaborate drawing on the houseman's blotter It was called These Also Came In front was the patient and behind and above him were many lightly sketched figures—some with labels such as Wife, Foreman, Joe the Barman, Allotment Pal Here was a ready made demonstration of that houseman's awareness, not only of the delicate variations in heart beats and breath sounds to which he had been listening, but also of the implications to his illness of the patient's home, family, job, and the whole complex of his interpersonal relationships beyond the walls of the hospital.

When a patient comes to a doctor he brings with him others who are a part of his situation or will help to get him out of it The doctor asks himself, "What does this patient need ? Is what he needs within his reach ? If so, can he reach for it ?" The patient is saying, "What is happening to me ? What does this mean to me ? What am I to expect ?" Almost inevitably these other people from outside the hospital are mixed up in the answers, and it is where any of the answers seem to present obstacles to diagnosis or cure that the doctor may bring the social case-work service into play

Few people distinguish between the individual approach of one human being to another and that of client and worker in the professional discipline called social case work This is understandable because very little has been done in speech or writing in this country to explain, by describing the case work method, the difference between the two Recently, in fact, a doctor who was trying to enlarge his understanding of its uses complained that, unlike medical men who explain an individual's disease in terms of the great physical systems of the body—circulatory, nervous, &c.—the social case worker never gave anything but examples, spoke in parables as it were, and left him to deduce the general principles

It is a fair criticism that good intentions and a desire to help have in the past been accepted as a substitute for careful formulation of the principles involved in social case work. But at this stage, though we are by no means ready to set down definite general principles, we have enough experience to deduce with a fair amount of certainty a few basic working assumptions

SOME BASIC PRINCIPLES

Doctors, like lawyers, have used the case method professionally for centuries to deal with an individual's problems in the light of his medical or legal situation Clergymen, kind neighbours, and others also use the case method How does social case work differ from these ?

Social case work is primarily a service offered by a professional worker with a certain body of knowledge, a mind trained in orderly thinking, and a personality sensitive to human relationships. It is offered to an individual who is experiencing some breakdown, small or great, in his ability to deal with his own life, either because he is a victim of circumstances or because he makes his own trouble, or because of a combination of these factors

The social case worker's body of knowledge should cover community resources and individual's rights in law, an understanding of human behaviour, of the social implications of disease, and of the factors and forces in society which help the individual to rise or which push him down

The technique which the social case worker has to learn consists in being able to offer the service derived from this knowledge in such a way that the person to whom it is offered can take hold of it and use it It is in the special nature of the relationship between the patient and the case worker that the value of the service lies

Although any understanding of people which attempts to be orderly will be limited by the nature of the material —there can be few things on this earth presenting more variables than a human being—still it is possible at this stage to deduce from our social case work experience the following general concepts

> It is a basic impulse in the normal man to want to manage his own affairs because there is no security to be had in being dependent on someone else
>
> The individual grows through relationships with other people
>
> Unless the damage is severe the growth process is strong so that temporary help will not produce dependency

The aim of the social worker is to help the individual to regain as much independence as possible by

> Giving him a special sort of understanding relationship in which he can practise, try things out as it were, in a protected environment
>
> Giving help freely in ways which do not impede growth or increase dependency

RÔLE OF THE CASE WORKER

There are two major ways in which help can be given to a person in need One is by manipulating the environment , the other is by giving direct help in interviews when the patient is encouraged to adopt habits of mind which will make him able to solve his own problems as they arise The degree to which one or other way is used depends both on the patient and his environment It will be obvious that some people of extremely unstable character and some defectives have not the capacity to solve their own problems even with help And there are others who are faced for a time at least with demands so impossible in relation to their strength that it becomes necessary that other people should direct their lives. For these the social case worker may have to help by providing, for instance, institutional care, a foster-home away from the neglectful parents, change of school away from the over ambitious teacher, or change of job away from the bad tempered foreman , or, more subtly, by drawing them into some situation which will give self-confidence a chance to grow, such as an invitation to join the patients' entertainment committee of a sanatorium, or by teaching a special skill to a disabled man who fears to leave the shelter of the hospital. All such action is based on an assumption that we know what is best for the patient

But usually a patient in whom the doctor encounters obstacles to treatment or recovery can make some reasonable adjustment of his own life through working out in interviews with a case worker what it is he wants to do and what kind of help he needs in order to do it This allows the patient to gain a new understanding of himself and the situation in the light of which he can take hold of the treatment offered him by the doctor and use it The case worker, by accepting the patient as he is, by the words in which she shows understanding of his trouble, holds up, as it were, a mirror in which he can see himself and his situation more clearly and see how to act

THE CASE-WORKER AND THE DOCTOR

It will be seen at once that this relationship is different from that of doctor with patient, and an understanding between the doctor and the social case worker of their different rôles is vital

Outside the hospital the individual who comes to an agency for help sees his problem as a social one, and that is why he brings it to a social worker In the medical social case work field the patient sees his problem as a medical one and he has therefore brought it to a doctor The doctor, who has become by tradition a symbolic figure with centuries of pain healing behind him, remains throughout the chief figure in this situation even if he only sees the patient once He automatically becomes the leader of whatever team is formed to deal with the patient's illness He is, in our culture, a symbolic figure of benevolent authority, and practically too he is the only one who can predict the stresses and strains involved in the illness It follows that where social case work is to be used in conjunction with medicine, then the responsibility of the doctor in enabling the patient to make use of the service, whether through general policies or personal introduction, cannot be too strongly emphasised Even where patients with social problems come to the case-worker by other routes in the hospital, this makes no difference—the action the case worker may take is supplementary, the relationship with the doctor is the basic one There is, in fact, no substitute for the doctor's genuine interest in the individual as a person and the patient's confidence in the doctor as someone who sincerely recognises his interests

Why, then, is not the medical social case worker's rôle an extension of the doctor's rôle—to do what the doctor would do if he had time? Years ago I was asked why medical social workers did not take the first part of a doctor's training before specialising, and recently it has been suggested that they should begin by taking part of the nurses' training

Possibly there is some confusion of thought in these points of view, springing from an incomplete understanding of the difference in the relationship of doctor with patient and of patient with social case worker The relationship of the doctor with patient—and incidentally of the nurse, and other specialists in the medical field, with the patient—is one of authority The doctor diagnoses, advises, orders, forbids, acts, treats, teaches, suggests, interprets, uses his personal influence and his symbolic aura to bring the patient to the goal which he, the doctor, has chosen The patient submits or rebels, accepts or refuses, is dependent or revolts from dependence on this authoritative figure With the medical social worker the relationship, to be successful, has to be entirely different The rôle of the case worker is to sit down with the patient and help him to work out his difficulty in his own way, not imposing her will or her goals on him, but looking at the whole situation from his angle and helping him to recognise and remove from his path those obstacles, personal or material, which impede his recovery and prevent his full cooperation with the doctor

To achieve this relationship the social case worker does not look at the patient's difficulties from any particular angle, such as law or medicine, but takes a general view The doctor, the lawyer, the clergyman, the industrialist each specialises in a particular service to the community The social case worker is a specialist too but of a different sort Her specialty is to attempt to understand the balance and interplay between all the services in the community and their relation to a particular patient who needs help

Thus, important as it is that the medical social case-worker should acquire knowledge of medicine later, it is even more important that she should spend the beginning of her training not in a hospital but in a position where she will receive the impact of all the great services and institutions equally

LYMPHOCYTIC CHORIOMENINGITIS

REVIEW OF TEN CASES

P R DUNCAN
M B, B Sc Manc, M R C P
SENIOR MEDICAL REGISTRAR

A E THOMAS
M B, B Sc Manc, M R C P
MEDICAL REGISTRAR

MANCHESTER ROYAL INFIRMARY

J O'H TOBIN
B M Oxfd, Dip Bact Manc
LECTURER IN BACTERIOLOGY IN THE UNIVERSITY OF MANCHESTER

SINCE the virus of lymphocytic choriomeningitis (L C M) was first isolated by Armstrong in 1934 it has been shown in many countries to be the cause of one form of "aseptic meningitis" This syndrome consists of a short febrile illness of fairly sudden onset with meningeal irritation Complete recovery follows The cerebrospinal fluid (C S F) contains an excess of lymphocytes and is bacteriologically sterile The cause is often assumed, but rarely proved, to be the virus of L.C.M Infections due to this virus have been reviewed by Farmer and Janeway (1942)

MacCallum (1949) has reported five cases of aseptic meningitis from various parts of England which were caused by the virus of Armstrong One of these came from a Manchester house where mice carrying this virus were caught In 6 months we have seen ten cases of L C M in Manchester Serological methods have indicated the ætiology in all cases, and the virus was isolated from four of them Green et al (1949) have pointed out that the ætiological diagnosis in many published cases has been poorly substantiated, since it was based on clinical grounds only Other diseases—e g, glandular fever and mumps—may present a somewhat similar picture The clinical features of cases proved to be due to the virus of L C M are therefore described

CASE RECORDS

Case 1 —A married woman, aged 30, was admitted on Feb 25, 1950, to Manchester Royal Infirmary under the care of Dr C S D Don She complained of headache, vomiting, and cough She had collapsed at work twelve days before, feeling cold and shivery, with aching pains in the limbs After three days in bed a productive cough and left-sided pleuritic pain had developed These symptoms had persisted, and occipital headache and photophobia were also present on admission

On examination she looked thin, pale, and ill Her temperature was 101 8°F, pulse rate 120, and respirations 24 per min No other abnormality was found, apart from neck stiffness and absent abdominal reflexes Radiography of the chest showed miliary mottling in both lung fields

Progress —On Feb 27 the temperature was 101°F, headache was severe, neck stiffness more pronounced, and Kernig's sign positive The resting pressure of the C S.F was 70 mm, and the fluid was turbid, containing 2760 cells per c mm (all lymphocytes), and protein 180 mg, glucose 29 mg, and chlorides 680 mg, per 100 ml No tubercle bacilli or other organisms were seen on microscopy or cultured from this or later specimens of C S F

Treatment —Tuberculous meningitis was provisionally diagnosed on the clinical picture, the chest radiogram, and the low C S F glucose level Intrathecal and intramuscular streptomycin was given and continued for 3 days On March 1 the remarkable clinical improvement suggested the possibility of a virus meningitis, so a fresh specimen of C S F was taken, and the virus of L C M was isolated from it Serum obtained on Feb 27 did not fix complement when tested with L.C.M antigen, but serum obtained a month later was positive to a titre of 1 in 16

Other Investigations —On Feb 27 the erythrocyte sedimentation rate (E S R.) was 20 mm in 1 hr (Wintrobe) and a blood count showed red cells 4,760,000 per c mm, Hb 13 g per 100 ml, white cells 8700 per c mm (polymorphs 66%, lymphocytes 21%) On March 2 a Paul Bunnell test was negative, and the Wassermann reaction of the C.S.F negative On April 2 radiography of the chest showed that the lung fields were clear

Recovery continued uneventfully and the patient was sent to a convalescent home on March 13

Associated Illness—The patient said that 2 weeks before she became ill her son, aged 8 years, had developed anorexia and vomiting, with headache and neck stiffness She recalled particularly the striking degree of neck rigidity After a week in bed the boy had recovered On March 30, 8 weeks after the beginning of his illness, the boy's serum gave positive complement-fixation with L C M. antigen to a titre of 1 in 16

Mice—The virus of L.C M. was isolated from mice trapped at the house where the patient and her son lived

Case 2—A girl, aged 18, employed as a machinist, was admitted on May 19, 1950, to the Manchester Royal Infirmary under the care of Dr Don She had complained of influenza like symptoms for 2 weeks—headache, anorexia, and mild fever—and five days before admission the headache had increased and been accompanied by vomiting.

On admission she did not look ill, her temperature was 99 6°F, pulse rate 86, and respirations 18 per min The only abnormal physical sign was slight neck rigidity The resting pressure of the C S F was 150 mm The fluid was clear and colourless and contained 200 cells per c mm (all lymphocytes), and protein 180 mg, glucose 47 mg, and chlorides 740 mg, per 100 ml

Diagnosis—It was felt that lymphocytic choriomeningitis was a possible diagnosis, particularly as we knew the patient worked in a raincoat factory within 20 yards of the house from which infected mice had been trapped (case 1) From blood and throat washings taken at this time the virus was recovered later None was isolated from the C S F

Other Investigations—On May 20 the E S.R was 22 mm in 1 hr (Wintrobe), and a white-cell count 6300 per c.mm. (polymorphs 47%, lymphocytes 42%) Repeated total and differential white cell counts were normal—e.g, 6600 per c.mm. (polymorphs 62%, lymphocytes 29%) on June 26 On May 27 chest radiography was normal, and Wassermann reactions of the blood and of the C.S.F were negative On May 20 and June 1 Paul Bunnell tests were negative

Progress—After lumbar puncture the patient had no further headache She went home on June 2 and returned 6 days later to report that a painless swelling of the neck had appeared the previous day but was now subsiding This was a slight enlargement of cervical and axillary glands on both sides, but no abnormality was found in the fauces or elsewhere The white cell count was 8100 per c mm. (polymorphs 64%, lymphocytes 31% large mononuclears 5%) and a further Paul Bunnell test was negative

Serum obtained 14 days from the onset gave negative complement-fixation with L C M antigen. A second specimen 3 weeks later was positive to a titre of 1 in 8 No neutralising or complement fixing antibodies were present in sera obtained from the girl s parents

Mice.—Unsuccessful attempts were made to trap mice in the patient's home and the raincoat factory, but rodent destructors had visited the factory only a few days previously

Case 10—A woman technician, aged 23, employed in the laboratory of one of us (J O H T) had been in good health until early February, 1950, when she lost 7 lb in weight in 5 weeks During this time she had a poor appetite but no other symptoms and continued at work, subsequently regaining her normal weight

As she had been handling laboratory mice infected with the virus of L C.M during this period, serological tests were made The complement fixation test showed the following titres Feb 27, positive 1 in 2, April 13, positive 1 in 8, April 23, positive 1 in 8, Sept 21, positive 1 in 2 Neutralising antibodies against L.C.M. virus were demonstrated in the sera obtained on April 23 and Sept. 21

The clinical features of cases 1–9 are summarised in table I.

CLINICAL FEATURES

Three clinical syndromes in man have been attributed to the virus of L C M (1) meningitis, which has been most frequently described, (2) encephalomyelitis (Findlay et al 1936), and (3) an influenza like infection without apparent involvement of the nervous system (Armstrong 1940) In the present series all were cases of meningitis except case 10, the laboratory infection Symptoms suggesting a virus infection developed 7–21 days before the onset of meningitis in eight cases, in the ninth patient they lasted 3 days These premonitory symptoms included general malaise, pains in the back and limbs, shivering, sweating, and striking anorexia This characteristic onset was first described by Baird and Rivers (1938) Cough was a prominent premonitory symptom in three of our cases and chest pain in two Two patients described a temporary remission of their general symptoms for a day or two before the onset of headache and meningitis

In the meningeal stage severe headache and neck stiffness were usually accompanied by photophobia and vomiting, six patients looked really ill. On passive flexion of the neck, rigidity was observed in all, and Kernig's sign was positive in six of the nine cases No paralysis, cranial-nerve lesion, or other sign suggesting encephalitis was observed. Signs of meningism lasted longer than a week in only two cases The C S.F pressure was raised in one, and within normal limits in six, of the seven cases in which it was recorded Two patients were afebrile, and in the remainder temperatures ranged from 100° to 104°F In the three patients with greatest fever there was slight drowsiness Three of our patients had transient lymph gland enlargement In one this

TABLE I—SYNOPSIS OF CLINICAL FEATURES OF 9 PROVED CASES OF LYMPHOCYTIC CHORIOMENINGITIS

Case no	Date of admission	Sex	Age (yr)	Premeningitic symptoms for (days)	Severity of illness	Special features	Diagnosis proved by	Environment

between the doctor and the social case-worker of their different rôles is vital.

Outside the hospital the individual who comes to an agency for help sees his problem as a social one, and that is why he brings it to a social worker. In the medical social case work field the patient sees his problem as a medical one and he has therefore brought it to a doctor. The doctor, who has become by tradition a symbolic figure with centuries of pain healing behind him, remains throughout the chief figure in this situation even if he only sees the patient once. He automatically becomes the leader of whatever team is formed to deal with the patient's illness. He is, in our culture, a symbolic figure of benevolent authority, and practically too he is the only one who can predict the stresses and strains involved in the illness. It follows that where social case work is to be used in conjunction with medicine, then the responsibility of the doctor in enabling the patient to make use of the service, whether through general policies or personal introduction, cannot be too strongly emphasised. Even where patients with social problems come to the case worker by other routes in the hospital, this makes no difference—the action the case worker may take is supplementary, the relationship with the doctor is the basic one. There is, in fact, no substitute for the doctor's genuine interest in the individual as a person and the patient's confidence in the doctor as someone who sincerely recognises his interests.

Why, then, is not the medical social case worker's role an extension of the doctor's rôle—to do what the doctor would do if he had time? Years ago I was asked why medical social workers did not take the first part of a doctor's training before specialising, and recently it has been suggested that they should begin by taking part of the nurses' training.

Possibly there is some confusion of thought in these points of view, springing from an incomplete understanding of the difference in the relationship of doctor with patient and of patient with social case worker. The relationship of the doctor with patient—and incidentally of the nurse, and other specialists in the medical field, with the patient—is one of authority. The doctor diagnoses, advises, orders, forbids, acts, treats, teaches, suggests, interprets, uses his personal influence and his symbolic aura to bring the patient to the goal which he, the doctor, has chosen. The patient submits or rebels, accepts or refuses, is dependent or revolts from dependence on this authoritative figure. With the medical social worker the relationship, to be successful, has to be entirely different. The rôle of the case-worker is to sit down with the patient and help him to work out his difficulty in his own way, not imposing her will or her goals on him, but looking at the whole situation from his angle and helping him to recognise and remove from his path those obstacles, personal or material, which impede his recovery and prevent his full cooperation with the doctor.

To achieve this relationship the social case worker does not look at the patient's difficulties from any particular angle, such as law or medicine, but takes a general view. The doctor, the lawyer, the clergyman, the industrialist each specialises in a particular service to the community. The social case worker is a specialist too but of a different sort. Her specialty is to attempt to understand the balance and interplay between all the services in the community and their relation to a particular patient who needs help.

Thus, important as it is that the medical social case-worker should acquire knowledge of medicine later, it is even more important that she should spend the beginning of her training not in a hospital but in a position where she will receive the impact of all the great services and institutions equally.

SINCE the virus of lymphocytic choriomeningitis (L.C.M.) was first isolated by Armstrong in 1934 it has been shown in many countries to be the cause of one form of "aseptic meningitis." This syndrome consists of a short febrile illness of fairly sudden onset with meningeal irritation. Complete recovery follows. The cerebrospinal fluid (C.S.F.) contains an excess of lymphocytes and is bacteriologically sterile. The cause is often assumed, but rarely proved, to be the virus of L.C.M. Infections due to this virus have been reviewed by Farmer and Janeway (1942).

MacCallum (1949) has reported five cases of aseptic meningitis from various parts of England which were caused by the virus of Armstrong. One of these came from a Manchester house where mice carrying this virus were caught. In 6 months we have seen ten cases of L.C.M. in Manchester. Serological methods have indicated the ætiology in all cases, and the virus was isolated from four of them. Green et al. (1949) have pointed out that the ætiological diagnosis in many published cases has been poorly substantiated, since it was based on clinical grounds only. Other diseases—e.g., glandular fever and mumps—may present a somewhat similar picture. The clinical features of cases proved to be due to the virus of L.C.M. are therefore described.

CASE RECORDS

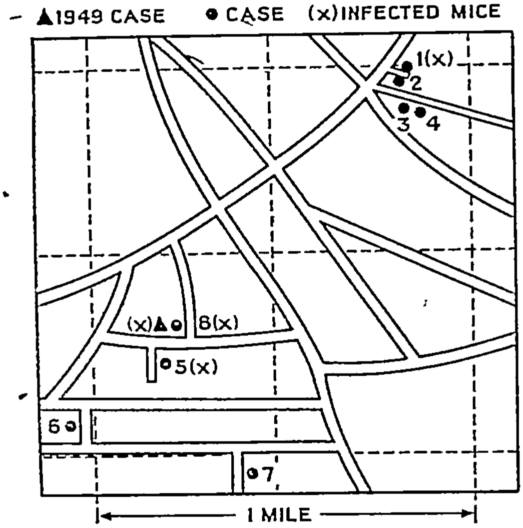
Case 1.—A married woman, aged 30, was admitted on Feb. 25, 1950, to Manchester Royal Infirmary under the care of Dr. C. S. D. Don. She complained of headache, vomiting, and cough. She had collapsed at work twelve days before, feeling cold and shivery, with aching pains in the limbs. After three days in bed a productive cough and left-sided pleuritic pain had developed. These symptoms had persisted, and occipital headache and photophobia were also present on admission.

On examination she looked thin, pale, and ill. Her temperature was 101.8°F, pulse-rate 120, and respirations 24 per min. No other abnormality was found, apart from neck stiffness and absent abdominal reflexes. Radiography of the chest showed miliary mottling in both lung fields.

Progress.—On Feb. 27 the temperature was 101°F, headache was severe, neck stiffness more pronounced, and Kernig's sign positive. The resting pressure of the C.S.F. was 70 mm., and the fluid was turbid, containing 2760 cells per c.mm. (all lymphocytes), and protein 180 mg., glucose 29 mg., and chlorides 680 mg., per 100 ml. No tubercle bacilli or other organisms were seen on microscopy or cultured from this or later specimens of C.S.F.

Treatment.—Tuberculous meningitis was provisionally diagnosed on the clinical picture, the chest radiogram, and the low C.S.F. glucose level. Intrathecal and intramuscular streptomycin was given and continued for 3 days. On March 1 the remarkable clinical improvement suggested the possibility of a virus meningitis, so a fresh specimen of C.S.F. was taken, and the virus of L.C.M. was isolated from it. Serum obtained on Feb. 27 did not fix complement when tested with L.C.M. antigen, but serum obtained a month later was positive to a titre of 1 in 16.

Other Investigations.—On Feb. 27 the erythrocyte-sedimentation rate (E.S.R.) was 20 mm. in 1 hr. (Wintrobe), and a blood-count showed red cells 4,760,000 per c.mm., Hb 13 g. per 100 ml., white cells 8700 per c.mm. (polymorphs 66%,



ıdence of human cases o lymphocytic choriomeningitis in relation to presence of infected mice.

jected both into guineapigs and into laboratory ice The guineapigs received 0 5 ml. of a 1 in 20 ulsion intraperitoneally, and the mice 0 03 ml. intra rebrally The virus was identified as described above Where there are no immediate facilities for isolating e virus the brains of house mice can be sent by post a virus laboratory if they are freeze dried, for the rus is best preserved in this way

SEROLOGICAL DIAGNOSIS

An extract of spleen from infected guineapigs was used s antigen in the complement fixation test (Smadel et al. 939) All positive sera were tested with an extract f normal guineapig spleen to exclude non specific xation Complete fixation at a serum dilution of 2 strongly suggests the presence of specific antibodies, ut in all our cases complete fixation took place at a ilution of 1 8 or 1 16 in at least one sample of serum, ence the question of doubtful positive results did not rise in the final diagnosis Neutralisation tests were erformed in mice

Serological diagnosis is the routine method of choice, ecause the virus cannot be isolated unless there is a irus laboratory within easy reach Three specimens f serum should be collected the first as soon as the iagnosis is suspected, the second at 3–4 weeks, and he third at 4 months after the onset of the illness

EPIDEMIOLOGY

Armstrong (1940) has discussed the question of a reservoir of the virus of L C M in house mice Farmer and Janeway (1942), reviewing the close association between this virus reservoir in mice and human cases of the disease, have described a single focus of infection in Boston, Massachusetts The only four patients with L C M observed by them in the negro population in 8 years all lived, at the times of their illnesses, "within two city blocks of each other"

In the present series all the patients, except cases 9 and 10, have come from two localised areas of Manchester (see figure) * Cases 1–4 lived or worked within 200 yards of each other The others lived within a radius of 400 yards Infected mice were caught in the house of case 7, only 70 yards from the one where mice harbouring the virus had been found 18 months previously (MacCallum 1949) The virus could not be isolated from mice caught in five other areas of the city

TREATMENT

In view of the rapid spontaneous improvement in all the cases of our series on admission to hospital, it would have been difficult to assess the effect of any drug with anti-virus properties, had such been used Lumbar puncture was usually followed by rapid relief of the headache

SUMMARY AND CONCLUSIONS

The clinical features of nine cases of aseptic meningitis, proved to be due to the virus of lymphocytic chorio meningitis (L C M), are described Influenza like symptoms characteristically developed 1–3 weeks before the onset of the meningeal phase

The laboratory findings and methods used and differential diagnosis are discussed

The C S F glucose levels may be low in L C M

A positive diagnosis can be made by isolating the virus from blood, C S F, or throat washings, and by demonstrating complement fixing and virus neutralising antibodies in the serum

A case of laboratory infection without apparent involvement of the nervous system is described

A close association exists between human cases and house mice also infected with the virus of L C M

Our thanks are due to Prof Robert Platt, Dr C S D Don Dr R Ellis, Dr D C Liddle, and Dr A Morgan Jones for permission to publish details of the patients under their care to Dr L Stent for obtaining the specimens from cases 4 5, and 6, and to Dr F O MacCallum for supplying a strain of virus with which antigen and immune serum were prepared We are indebted to Dr C Metcalfe Brown, M O H of Manchester, for his department's help in obtaining mice for examination, and to Prof H. B Maitland for helpful criticism and advice

Births and Deaths in War and Peace

The dramatic qualities of a national stocktaking by census should not be allowed to obscure the vital interest of the routine publications by the Registrar General As earnest of his wish to overhaul the way lost as a result of the war, he has put out both the medical statistical tables for 1949[1] and a review of the civil statistics for the period 1940–45[2] Taken together, they give an up to date picture of the trends in birth and death rates since the turn of the century and a preview of the net result which may appear in the tabulations of the latest census

While the 1949 death rate of 11 8 per 1000 was a little higher than in 1948, the consistent improvement in mortality experience in the under 35s continued—for children less than 5 years old the death rate was about an eighth of what it was a hundred years ago and just over half of its level in 1939 The infant mortality rate at 33 9 per 1000 approached the 1950 "all time low" of 29 8 per 1000 Among older men in particular, however, there appeared some disquieting features Real increase in the cancer death rate was indicated by an increase in the comparative mortality index, which takes account of the ageing of the population, a rise of some 6% since 1938 is largely due to the increase

*Lower limit of normal = 45 mg per 100 ml

came on during the meningeal stage, and in the other two in early convalescence

LABORATORY FINDINGS

C.S.F.—Results of C.S.F. examinations from nine cases are shown in table II The total cell count ranged from 28 to 4200 per c mm, and lymphocytes predominated, comprising 75–100% of the cells We found the glucose level to be lower than 45 mg per 100 ml in three of the eight cases in which quantitative estimations were made, although the glucose has usually been stated to be normal in this condition (Van Rooyen and Rhodes 1948, Rivers 1948) These findings, however, conform with those of Green et al (1949), who described low glucose levels in seven of their twenty-one cases

Blood—White cell counts were made in five of our cases and were in no way abnormal The Paul-Bunnell test was negative in all of eight cases in which it was done, these included the three with transient lymph gland enlargement In two of these, repeated Paul Bunnell tests were negative

DIFFERENTIAL DIAGNOSIS

A lymphocytic meningitis may also develop in poliomyelitis, virus encephalitis, mumps, Bornholm disease, herpes simplex, lymphogranuloma inguinale, syphilis, Weil's disease, canicola fever, torulosis, toxoplasmosis, mastoid disease, and cerebral abscess In our experience the two conditions which gave rise to difficulty in iagnosis were tuberculous meningitis and glandular ver

An insidious onset is common to tuberculous meningitis nd lymphocytic choriomeningitis Cough and vomiting may be present during the premeningeal stage of both diseases Low C.S.F. glucose levels are found in tuberculous meningitis, but they are also found in some cases of lymphocytic choriomeningitis, adding to the difficulty of early diagnosis If tubercle bacilli are not identified in the C.S.F., the diagnosis is usually clear within a few days Recovery from lymphocytic choriomeningitis is rapid, and improvement in the patient's general condition is obvious within 48 hours

When neurological complications occur in glandular fever, lymph gland enlargement may be very slight (Tidy 1946) Negative Paul-Bunnell tests and the absence of the characteristic blood changes help to distinguish lymphocytic choriomeningitis from glandular fever

Premonitory symptoms resembling influenza, and a brief remission before the onset of meningism, support a diagnosis of lymphocytic choriomeningitis The presence of mice and the knowledge of other cases having occurred in the immediate neighbourhood may be of value

Final proof is given by isolating the virus of lymphocytic choriomeningitis from the C.S.F., blood, or nasopharynx, and by demonstrating the presence of complement-fixing and virus neutralising antibodies in the patient's serum Complement fixing antibodies develop 2–3 weeks after the onset of the illness—i e, during or shortly after the meningeal phase—and persist for 6 months or longer Neutralising antibodies appear 2–3 months, or even later, after the onset and may remain for years

In our series the virus was isolated from the C.S.F. in three cases and from the blood and throat washings in another Complement fixation tests were positive in all Neutralising antibodies were demonstrated in five of the six cases where this was attempted (table III)

ISOLATION OF VIRUS

From Human Sources

We were able to isolate the virus from the C.S.F. when the cell count was greater than 500 per c mm, as were Green et al (1949) We therefore suggest that, if the cell count is above this level, the material of choice for the attempted isolation of the virus is the C.S.F., or, if the cell count is below this level, blood and throat washings should also be used. Guineapigs and mice, or sometimes guineapigs only, were inoculated within 10 minutes of obtaining the specimens from the patient Stocks of laboratory animals were free from L.C.M. infection, a necessary precaution when dealing with this virus In no case in which both guineapigs and mice were used was virus isolated from one species and not from the other

Two guineapigs were injected intraperitoneally with up to 5 ml. of material, and five mice intracerebrally with 0 03 ml and intraperitoneally with amounts up to 1 ml One guineapig was killed on the 4th day after inoculation, and an emulsion of its spleen was injected intracerebrally into mice The other guineapig was kept and bled after 14 days or just before death if this occurred earlier Usually death took place between the 14th and 16th day when the guineapigs were infected with the Manchester strain. The guineapig serum was then tested for complement fixing antibodies The virus was further identified from the typical syndrome produced by intracerebral inoculation of mice, by neutralisation and cross protection tests, and by complement fixation of the infected guineapig spleen with immune serum

From House Mice

Virus was isolated from house mice as long as 36 hours after trapping The brains were removed and

Incidence of human cases o lymphocytic choriomeningitis in relation to presence of infected mice.

injected both into guineapigs and into laboratory mice. The guineapigs received 0·5 ml. of a 1 in 20 emulsion intraperitoneally, and the mice 0·03 ml. intracerebrally. The virus was identified as described above.

Where there are no immediate facilities for isolating the virus the brains of house mice can be sent by post to a virus laboratory if they are freeze dried, for the virus is best preserved in this way.

SEROLOGICAL DIAGNOSIS

An extract of spleen from infected guineapigs was used as antigen in the complement fixation test (Smadel et al. 1939). All positive sera were tested with an extract of normal guineapig spleen to exclude non specific fixation. Complete fixation at a serum dilution of 1 : 2 strongly suggests the presence of specific antibodies, but in all our cases complete fixation took place at a dilution of 1 : 8 or 1 : 16 in at least one sample of serum; hence the question of doubtful positive results did not arise in the final diagnosis. Neutralisation tests were performed in mice.

Serological diagnosis is the routine method of choice, because the virus cannot be isolated unless there is a virus laboratory within easy reach. Three specimens of serum should be collected: the first as soon as the diagnosis is suspected, the second at 3–4 weeks, and the third at 4 months after the onset of the illness.

EPIDEMIOLOGY

Armstrong (1940) has discussed the question of a reservoir of the virus of L.C.M. in house mice. Farmer and Janeway (1942), reviewing the close association between this virus reservoir in mice and human cases of the disease, have described a single focus of infection in Boston, Massachusetts. The only four patients with L.C.M. observed by them in the negro population in 8 years all lived at the times of their illnesses, "within two city blocks of each other."

In the present series all the patients, except cases 9 and 10, have come from two localised areas of Manchester (see figure).* Cases 1–4 lived or worked within 200 yards of each other. The others lived within a radius of 400 yards. Infected mice were caught in the house of case 7, only 70 yards from the one where mice harbouring the virus had been found 18 months previously (MacCallum 1949). The virus could not be isolated from mice caught in five other areas of the city.

---

* Since this paper was written we have seen a further four proved cases from these two Manchester foci of infection.

TREATMENT

In view of the rapid spontaneous improvement in all the cases of our series on admission to hospital, it would have been difficult to assess the effect of any drug with anti-virus properties, had such been used. Lumbar puncture was usually followed by rapid relief of the headache.

SUMMARY AND CONCLUSIONS

The clinical features of nine cases of aseptic meningitis proved to be due to the virus of lymphocytic choriomeningitis (L.C.M.), are described. Influenza-like symptoms characteristically developed 1–3 weeks before the onset of the meningeal phase.

The laboratory findings and methods used and differential diagnosis are discussed.

The C.S.F. glucose levels may be low in L.C.M.

A positive diagnosis can be made by isolating the virus from blood, C.S.F., or throat washings, and by demonstrating complement fixing and virus neutralising antibodies in the serum.

A case of laboratory infection without apparent involvement of the nervous system is described.

A close association exists between human cases and house mice also infected with the virus of L.C.M.

Our thanks are due to Prof. Robert Platt, Dr. C. S. D. Don, Dr. R. Ellis, Dr. D. C. Liddle, and Dr. A. Morgan Jones for permission to publish details of the patients under their care; to Dr. L. Stent for obtaining the specimens from cases 4, 5, and 6; and to Dr. F. O. MacCallum for supplying a strain of virus with which antigen and immune serum were prepared. We are indebted to Dr. C. Metcalfe Brown, M.O.H. of Manchester, for his department's help in obtaining mice for examination; and to Prof. H. B. Maitland for helpful criticism and advice.

*Lower limit of normal = 45 mg per 100 ml

came on during the meningeal stage, and in the other two in early convalescence

LABORATORY FINDINGS

C S F—Results of C S.F examinations from nine cases are shown in table II The total cell count ranged from 28 to 4200 per c mm, and lymphocytes predominated, comprising 75–100% of the cells We found the glucose level to be lower than 45 mg per 100 ml in three of the eight cases in which quantitative estimations were made, although the glucose has usually been stated to be normal in this condition (Van Rooyen and Rhodes 1948, Rivers 1948) These findings, however, conform with those of Green et al (1949), who described low glucose levels in seven of their twenty one cases

Blood—White cell counts were made in five of our cases and were in no way abnormal The Paul-Bunnell test was negative in all of eight cases in which it was done, these included the three with transient lymph gland enlargement In two of these, repeated Paul Bunnell tests were negative

DIFFERENTIAL DIAGNOSIS

A lymphocytic meningitis may also develop in poliomyelitis, virus encephalitis, mumps, Bornholm disease, herpes simplex, lymphogranuloma inguinale, syphilis, Weil's disease, canicola fever, torulosis, toxoplasmosis, mastoid disease, and cerebral abscess In our experience the two conditions which gave rise to difficulty in diagnosis were tuberculous meningitis and glandular fever

An insidious onset is common to tuberculous meningitis and lymphocytic choriomeningitis Cough and vomiting may be present during the premeningeal stage of both diseases Low C S F glucose levels are found in tuberculous meningitis, but they are also found in some cases of lymphocytic choriomeningitis, adding to the difficulty of early diagnosis If tubercle bacilli are not identified in the C S.F, the diagnosis is usually clear within a few days Recovery from lymphocytic choriomeningitis is rapid, and improvement in the patient's general condition is obvious within 48 hours

When neurological complications occur in glandular fever, lymph gland enlargement may be very slight (Tidy 1946) Negative Paul Bunnell tests and the absence of the characteristic blood changes help to distinguish lymphocytic choriomeningitis from glandular fever

Premonitory symptoms resembling influenza, and a brief remission before the onset of meningism, support a diagnosis of lymphocytic choriomeningitis The presence of mice and the knowledge of other cases having occurred in the immediate neighbourhood may be of value

Final proof is given by isolating the virus of lymphocytic choriomeningitis from the C S F, blood, or nasopharynx, and by demonstrating the presence of complement fixing and virus neutralising antibodies in the patient's serum Complement fixing antibodies develop 2–3 weeks after the onset of the illness—i e, during or shortly after the meningeal phase—and persist for 6 months or longer Neutralising antibodies appear 2–3 months, or even later, after the onset and may remain for years

In our series the virus was isolated from the C S F in three cases and from the blood and throat washings in another Complement fixation tests were positive in all Neutralising antibodies were demonstrated in five of the six cases where this was attempted (table III)

ISOLATION OF VIRUS

From Human Sources

We were able to isolate the virus from the C S F when the cell count was greater than 500 per c mm, as were Green et al (1949) We therefore suggest that, if the cell count is above this level, the material of choice for the attempted isolation of the virus is the C S F, or, if the cell count is below this level, blood and throat washings should also be used. Guineapigs and mice, or sometimes guineapigs only, were inoculated within 10 minutes of obtaining the specimens from the patient Stocks of laboratory animals were free from L C M infection, a necessary precaution when dealing with this virus In no case in which both guineapigs and mice were used was virus isolated from one species and not from the other

Two guineapigs were injected intraperitoneally with up to 5 ml. of material, and five mice intracerebrally with 0 03 ml and intraperitoneally with amounts up to 1 ml One guineapig was killed on the 4th day after inoculation, and an emulsion of its spleen was injected intracerebrally into mice The other guineapig was kept and bled after 14 days or just before death if this occurred earlier Usually death took place between the 14th and 16th day when the guineapigs were infected with the Manchester strain. The guineapig serum was then tested for complement fixing antibodies The virus was further identified from the typical syndrome produced by intracerebral inoculation of mice, by neutralisation and cross protection tests, and by complement fixation of the infected guineapig spleen with immune serum

From House Mice

Virus was isolated from house mice as long as 36 hours after trapping The brains were removed and

worst, it turned out to be genuine but so miserably lukewarm as to be hardly eatable.

If there is one thing one would expect to be first-class in an Indian hotel it is tea. But no—the beverage called tea was no more recognisable than the corresponding liquid of English station refreshment-rooms. (I once watched with relish a middle-aged woman customer and the two waitresses arguing over the nature of a cup supplied as coffee. The customer contended that it was tea and one waitress firmly agreed with her, while the other waitress was certain it was coffee. They sipped and argued in turn until the cup was empty, when the verdict had to be left as non-proven.) In complete contrast was the Ceylon tea, undoubtedly the best I ever tasted. I am told on good authority that there is nothing to choose between Indian and Ceylon teas as exported; but after this tour it will take a lot to convince me that Ceylon is not far the better of the two.

Returning to the monotony of the menus, hardly any hotels provided edible fruit. Here were we from the West with mouths watering from our visions of mangos and yams, built up from memories of the pictures in "Little Black Sambo" and "Little Black Quibba" (was he the one who cured his mother by providing a basket of mangos every day?), and all we got was stewed prunes or oranges.

Charges everywhere were high by English standards. But the most annoying feature was that the charge per day includes all meals; so however much one dines out the bill remains as high as ever.

* * *

Inspecting the fluid level in the battery of the modern car presents serious physical and optical difficulties. For a long time past I have thought about introducing a simple instrument for this purpose on the lines of a laryngoscope; but I have been disappointed to find that my garage man has beaten me to it by using a piece of broken mirror and a long arm. However, I am not unduly discouraged by the loss of priority because there still seems to be a big field for better diagnostic methods and manipulative technique in the automobile world. The sight of a mechanic trying to retrieve a small nut from an awkward corner makes me want to dash off for a suitable endoscopic instrument and a pair of crocodile forceps, if only to show him that we doctors are not such fools with our hands as he thinks. Consulting work in this specialty might be interesting, and there would be no complaints from patients or committees. Doubtless there would be hazards. Would the defence societies support me if I got into legal trouble for leaving a broken cystoscope bulb inside the cylinder head of somebody's ultravaluable post-war car?

* * *

The little boy was reading the label on a bottle in the family medicine-cupboard—from which he and his sister had often been dosed. "Up to six months half a teaspoonful," he read to himself, "six months to a year one teaspoonful; one to four years two teaspoonfuls." Then, turning to his mother, "Mummy, it must be dreadful to have a cough for four years."

* * *

Preserving cadavers for dissection in the Tropics is not so difficult as one might suppose. Evidently my African driver did not realise this fact, for when I caught him peering with disapproving eyes through the open door of the dissecting room, he asked me, "Why the bodies no rust, Sah?"

* * *

Some say you never see anything interesting in general practice; but I just met our local acromegaly chatting to our local syringomyelia in the middle of the village street. Is this a record?

PLURAL SHOCK

As I am walking on the links
I hear the hum of a Hillman Minx.
But stay—so loud the noise impinges,
Can it be several Hillmen Minges?

Letters to the Editor

MEDICAL RESEARCH IN REGIONAL HOSPITALS

SIR,—The National Health Service Act (1946) extended the power of the Minister for supporting medical research to regional hospital boards, boards of governors, and hospital management committees. The memorandum on this subject (R.H.B. [49]145) redefined the policy in relation to the Medical Research Council. The Ministry was to confine itself to promoting such investigation as can best be done within the framework of the health services for which it has immediate responsibility. The council was left with the wider, and particularly the long term, problems of medical research.

In a previous letter[1] I drew attention to the difficulty of financing research by hospital management committees as a result of the present system of budgeting. In your leading article[2] you underlined the danger of any hindrance to medical research. Since my last letter I have continued to make inquiries about the financing of research outside the teaching centres, and the picture I find is encouraging.

Six regional boards—Birmingham, Oxford, Newcastle, South western, South-west Metropolitan, and Sheffield—have recognised the need for stimulating medical research within their regions, and have appointed special research committees. These committees are backed either by Exchequer funds included in the regional-board budget or by endowment funds, and three research committees have substantial sums at their disposal. Other regions support certain specific research projects, or have available funds which could be used. There is no doubt that work involving appreciable sums of public money should have guidance from a research committee. Such guidance is, of course, available for those working under the Medical Research Council.

Simple clinical medical research in relation to the hospital service is an essential aspect, if only from the economic angle, in view of the high cost of inpatient treatment. Local interest in research should be stimulated by regional boards, but this need not prejudice alternative application for grants from the M.R.C. or other medical foundations. In my opinion, there is also scope for activity at the hospital-management-committee level so that small sums could be made available quickly for special apparatus or extra clerical assistance; but such moneys could come, not from Exchequer sources, but from the "free moneys" available to the hospital. Public interest could easily be stimulated in a local research fund, and the use of "free moneys" raises no difficulties in budgeting.

Fellowships related to the big medical foundations or academic centres are another valuable source of research expenditure. With the rising cost of living, however, some are no longer a reasonable financial proposition except for men with private means, and clearly reconsideration of them is needed.

I believe that with the development of regional research committees and with small sums readily available to hospital management committees, the whole attitude towards medical research in this country would undergo a radical change. It would no longer be considered a prerogative of the academic centres but part of the daily task at the regional hospital. Clinical research would become a life interest instead of being a means to an end—to get consultant status. The time is particularly opportune, for there are many younger consultants appointed to regional hospitals with recent experience of clinical or laboratory research; and, given suitable support, they could continue to make useful contributions to medical progress. The stimulation among men in the number of deaths from cancer of the lung, which rose from 3751 in 1939 to 9327 in 1949 Men, too, more commonly die by accidental violence and, even more significantly, by their own hand

[1] *Lancet*, 1951, i, 34.
[2] Leading article. *Ibid*, p. 19.

The importance of psychological factors thus implied is equally clear in the trends in marriage and birth rates Mating and reproduction are clearly affected by changes in the psychological climate which attend the fluctuations in our national fortune Although the birth rate had been falling continuously from its peak in the 1870s, the first world war produced a drastic ebb in the tide of births which did not expend itself until the rate reached its nadir of 14 4 in the depression year of 1933 The slight recovery to 15 1 achieved by 1938 was checked by the beginning of the second world war until, in 1941, when the national outlook seemed at its worst, the rate reached the lowest point in the history of registration in this country The turn in the tide of battle was accompanied by a dramatic reversal of this pessimistic trend, from 1944 onwards the rate soared up to a peak of 20 5 in 1947 Inevitably, perhaps, the reproductive stimulus of even militarily successful war had its less desirable side, while of the 94,381 extramaritally conceived births in 1938 some 70% were regularised by the later marriage of the parents, only 49% of the 516,355 such births in 1940–45 were thus regularised before the arrival of the child No doubt this was due to the separation which war movements enforced, but it is disappointing to find that even after the war many of the parents concerned took no advantage of the Legitimacy Act of 1926 Marriage rates are of course just as much influenced by variations in national morale, they followed the same trend of slump and boom as did the nation's economy and birth rate The loosening of moral standards reflected in illegitimacy is also seen in divorce, petitions rose in number from 10,304 in 1938 to 25,789 in 1945 But the perennial optimism of our race is seen in the fact that as many as three quarters of these divorcees remarried

With any luck, the surprising buoyancy of our national income may be mirrored in a continuation of the combined effect of the trends in births and deaths which produced between 1939 and 1945 a real acceleration in the rate of national increase

The First Quarter

The Registrar General[1] announces that provisional figures for England and Wales for the first quarter of this year show that the birth-rate has again fallen, while the stillbirth-rate has increased slightly compared with the first quarter of 1950 The death-rate was the highest for any March quarter since 1940

The birth rate was 16 3 per 1000 population, compared with 16 7 and 17 3 in the corresponding quarters of 1950 and 1949 The stillbirth-rate was 23 6 per 1000 total live and still births, compared with 22 9 in the first quarter of 1950 The death-rate was 19 0 per 1000 population, compared with 14 0 and 14 9 in the corresponding quarters of 1950 and 1949 The infant-mortality rate was 38 2 per 1000 related live births, compared with 36 8 and 40 4 in the same quarters of 1950 and 1949 In 1938 for the same period the rate was 69 3 per 1000 related live births

Immunisation in London

In a report on the London County area in the last quarter of 1950, the medical officer of health states that smallpox vaccinations fell slightly from 58% of births to 54%, but in the last quarter of 1949 the figure was 38% Diphtheria immunisations were maintained, the records indicate that nearly 62% of infants under 5 years of age have been immunised, and that the percentage is gradually rising Whooping cough and combined whooping-cough and diphtheria immunisations continue to decline steeply

In England Now

A Running Commentary by Peripatetic Correspondents

ONE disadvantage (the only one ?) of reading the weekly medical journals is the amount of half-baked information one acquires concerning the theory and treatment of obscure diseases outside one's own field When one gets ill these snippets keep returning to plague us Take my sciatica, for example During my first few days in bed, in the lucid intervals between doses of an analgesic which "leaves the mind clear," my thoughts ran mostly on the operations I had read about—what was it those chaps had said ? Not all cases needed an operation, certainly, but what cases, and why ? Fortunately my G P still believes sciatica has something to do with sitting on a cold bench, so he didn't even mention surgery,

In the second week, the risks of addiction to one or other (or both) of the drugs I was living on, began to loom up The neurologist who gave me "the works," complete with pin, cotton-wool, tuning fork, and hammer, and confidently confirmed the diagnosis, pooh poohed my fears and advised me to continue expectant treatment with a slightly different analgesic, he wouldn't hear of operation In the third week, bed sores became my chief preoccupation—if I got one would they try that treatment by excision there was an annotation about ? My physiotherapist colleague said certainly not but *he* seemed preoccupied with some new tricks of thumping, pressing, and twisting of the spine which left me all set for exacerbation of my acute symptoms. Apparently none of the gadgetry of physical medicine could be brought to my bedside except in a large lorry, and as I refused to sanction the building of a ramp on to my house, the only outcome of this visit was a cheery word and a good prognosis

By the fourth week I was eagerly searching the periodicals for articles, letters or even advertisements describing new treatments for my disease By now I was so well softened up that I would gladly accept any of them—even laminectomy seemed quite a simple and safe operation But when my orthopædic colleague arrived, after confirming the diagnosis (on the story alone) and giving me another reassuring prognosis over a cup of coffee, he only murmured "Plaster jacket tomorrow," adding just before the door closed behind him, "No question of operation," to my intense relief No operation ! How was it I hadn't realised before what a clever chap he was ?

So the plaster was applied, and the effect of my Diogenes like existence was magical The new encumbrance entirely occupied my mind, leaving no place for such trivialities as pain in my leg Before long, plaster-barrel and all, I could hobble back to work, with a chest like a pouter-pigeon's, back erect, sore groins, and an eternal longing to scratch where scratching was impossible, living only for the day when I could have a bath again

* * *

I agree with much of the criticism levelled at English hotels, but it is only fair to say that a 20,000 mile tour made this winter to India, Malaya, and East Africa (by air, of course) confirmed my impression that they are not unique in their imperfections And I saw few signs of improvement since my last trip three years ago

In India some of the discomforts arise from the chronic shortage of food, specially sugar and fats, and so are unavoidable The allowance of sugar for breakfast is one cube, and though a second helping is supplied on request it also will consist of a single cube The scarcity of fat shows itself particularly in the total lack of soap in hotel bedrooms, reminiscent of war time Britain My main objection, however, is to the catering Instead of concentrating on their own national dishes and showing us how they should be served, they give the visitor nothing but badly cooked versions of familiar Western dishes During my week in India curry appeared on the menu only once, but we had an inferior imitation of roast beef and yorkshire pudding nearly every day Then the food was seldom hot when it reached us In one famous Eastern hotel, for example, when I ordered the "Scotch pheasant" from the menu, expecting the pamphlets, and to organise social activities (e g, tennis tournaments, whist drives) in order to raise money to pay for the lectures, pamphlets, and other publications This last activity is very important because, even if the money was obtainable elsewhere, social activities are the best method of encouraging people to use the word "cancer" openly, and not to speak of it in whispers

---

[1] Registrar General s Return for the Week ended April 14 H M Stationery Office Pp 20 9*d*.

I understand that the Central Council for Health Education are interested in these suggestions In Durban I lately gave a talk on this subject to a mixed audience of medical, paramedical, and lay people, with the result that at the end of the meeting a Durban Cancer Education Committee was formed to carry out the duties mentioned above Surely the time is overdue for something to be done in this country to prevent thousands of unnecessary deaths and much untold suffering

London W 1 MALCOLM DONALDSON

SMOKING AND CANCER

SIR,—Dr Joules argues (April 7, p 797) that we should attempt to prevent carcinoma of the lung by publicising the close relation between this condition and smoking I do not wish to gainsay that this may be the best preventive measure, but before the argument can be regarded as watertight two assumptions must be made (1) that the reported increase in lung cancer is real, and (2) that the relation with smoking is causal.

For the moment let us pass by the first assumption but examine the second, because there seems to be a possible loophole so far unmentioned. Though smoking need not be the cause of lung cancer, it certainly seems reasonable to look for an environmental influence when incidence has apparently increased so greatly in recent years Concentration on environment may lead, however, to the constitutional aspect being ignored, and this aspect is not without interest Sheldon et al.[1] published two remarkable diagrams illustrating the tendency for carcinoma of the breast and carcinoma of the uterus to occur in association with one particular kind of physique, each series consisted of 100 consecutive cases It may be that carcinoma of the lung also occurs most frequently in individuals of certain build There is some evidence, too, that the habit of smoking is more prevalent in men of certain physique, and if this physique were the same as that of subjects disposed to cancer, then smoking could be closely associated with cancer without in fact causing it. The accompanying table gives the smoking habits of 308 undergraduates whose physique has been typed using Sheldon's metric technique

PERCENTAGE DISTRIBUTION OF NON-SMOKERS AND SMOKERS BY DOMINANCE OF SOMATOTYPE

Dominance	No	Non-smokers		Smokers	
		No	%	No	%
Endomorphs	56	29	51·8	27	48·2
Endomorph mesomorphs	31	17	55·0	14	45·0
Mesomorphs	118	69	58·5	49	41·5
Mesomorph-ectomorphs	17	10	59·0	7	41·0
Ectomorphs					
Mesomorphic	46	31	67·4	15	32·6
Endomorphic	40	30	75·0	10	25·0

Is it just coincidence that the highest prevalence of smoking in young men, and of breast and uterine cancer in women, occurs in those of similar body build? Or that tall thin people were most often non smokers and also comparatively free from cancer? Perhaps smoking acts as a trigger to a gun constitutionally loaded, and people of lanky build may smoke with relative impunity or merely smoke less because they more often dislike smoking

That smoking can be reduced is shown by a reduction since 1947 in the proportion of undergraduates smoking—a reduction usually attributed to increasing cost through taxation I do not wish to discuss either methods of reducing smoking or the thorny question of creating cancerphobia, but I would like to suggest the adoption, now that satisfactory techniques are available, of records of physical constitution in future research on cancer

R W PARNELL

Institute of Social Medicine Oxford.

Physician in charge, Student Health Service.

GENERAL PRACTITIONER AND CONSULTANT

SIR,—I disagree entirely with Dr Robertson's suggestion (April 14) that there is a cleavage between the general practitioner and consultant I can only speak of my own town, Southampton, where, I strongly hold, there is a wonderful relationship between G.P.s and the consulting staffs of the hospitals

As chairman of the clinical meetings which are held once a month, I find that there is a considerable amount of exchange of opinion between G.P.s and consultants In many instances cases are shown by G.P.s, and, believe me, the standard of their presentation is very high

I regret this continual suggestion in print of the so called "gulf" or "cleavage" between G.P.s and consultants, which does not appear to exist in this town The medical ability of the G.P. here is on a high level, and so why this suggestion of a falling standard? The position may be different in other parts of the country

HAROLD J BOWER

Southampton.

Consulting Physician Royal South Hants and Southampton Hospital.

URETHRAL CARUNCLES

SIR,—Most gynæcologists will agree with Mr Campbell Begg (April 14) that partial prolapse of the female urethral mucosa is a common finding, and that true caruncle is relatively rare Many will also agree that the symptoms arising from such a caruncle often correspond with a trichomonas infection of the vagina Yet few, I hope, will sanction his provocative condemnation of the very existence of caruncles The adenomatous polyp of the meatus, and the exquisite tenderness of pedunculated fragments of granulation tissue, are lesions whose existence can hardly be doubted

Regarding terminology, the fact that the term has no pathological significance does not prevent its useful employment Does Mr Begg, I wonder, wage war against polyps, on the grounds that they are common to the surgery of the nose, bowel, and pelvis? Does he reject such a vintage term as epulis, which was employed before the microscope proved its protean nature? There may be no urethral caruncles in his Dominion, but there are still a few in the mother country

Birmingham W G MILLS

SIR,—Mr Campbell Begg rightly asserts that the majority of patients referred for opinion have in fact small areas of prolapsed urethral mucosa which cause no symptoms We observed this condition in 10 out of 58 normal menopausal women, and suggested that these "caruncular areas" were physiological.[1]

Mr Campbell Begg describes a type of caruncle which bled with friction. In our experience bleeding is not uncommon in a true caruncle which may also be tender and cause dysuria. The condition, however, can easily be differentiated from an asymptomatic prolapse of the urethral mucosa. Cautery usually cures a bleeding caruncle and relieves symptoms of dysuria and discomfort, the condition, however, may recur and once again give rise to symptoms of many small growing points of knowledge in this country could be achieved at a very small cost and might substantially raise the standard of hospital practice outside the teaching centres

SALICYLATE, GENTISATE, AND CIRCULATING EOSINOPHILS

SIR,—The leading article and the paper by Dr Meade and Dr Smith in your issue of April 7 prompt us to make the following observations on salicylates and adrenocortical activity

We have shown in animals and in man that heavy doses of salicylates mobilise "anti-arthritic" adrenal hormones[1] Further, we have attempted to ascertain the nature of these hormones and the amount mobilised, but hitherto no definite conclusion has been possible It seems, however, reasonable to say that the therapeutic effect of salicylates can, at present anyhow, hardly be explained in this way

Dr Meade and Dr Smith, in contradicting our findings on circulating eosinophils, *mention only part of our results* We wrote [2]

> *Small* salicylate doses with serum levels at the 4th hour of 20–30 mg per cent and below (4–5 g of salicylate) did not produce any fall of the eosinophils (16 cases), while in the case of levels of 30–35 mg per cent (6 g single dose) the decrease is about 50 per cent of the original (8 cases) *Higher* levels (7–10 g within 4–5 hours) are accompanied with more pronounced diminution of the absolute eosinophil count (3 cases)

We confirmed these results in most of our subsequent cases The eosinophil count, however, is also regulated by unknown factors, other than the hypophyseo adrenal system , and it is thus not surprising that results differ

Dr Meade and Dr Smith, however, gave 5 1 g salicylate (gr 75) and determined the (expected maximal) serum level two hours after the dose was taken This does not seem adequate for checking our results from 6–10 g doses and estimating the salicylate level at the 4th hour Also our method of salicylate determination was different [3]

Finally, it should be noted that, as the Mayo Clinic group have repeatedly remarked,[4] ' Cortisone ' does not regularly produce eosinopenia in man

E KELEMEN
M MAJOROS

ANGOR ANIMI

SIR,—In your annotation last week you quote the late Professor Ryle as saying that he had never met this symptom in its major form as a symptom of psychological disease, and that it cannot be removed by reassurance or by any other psychotherapeutic measures

I recently saw what appeared to be a classical case, apparently fitting very closely Russell Brain's description of

> a sense of disordered action of the heart, such as slowing, irregularity or increased rapidity of the heart beats In some cases there is an intense feeling of impending death—angor animi the patient remains perfectly still the surroundings seem to the patient very distant the extremities cold but the patient experiencing a sense of chill '

It is of additional interest, in view of John Hunter's and Professor Ryle's experience that the breathing appeared to be arrested, that my patient said she could not work her chest

Physical examination, including electrocardiography and electro encephalography, was entirely negative Emotional factors were suspected, but could not be confirmed by an experienced psychiatrist A chance remark then induced the patient to send for the psychiatrist again, because she had told him " a pack of lies ' It emerged—to quote the psychiatrist—that, as a result of emotional complications concerned with a favoured twin, she had, in early childhood, developed a vivid phantasy which occurred during the night but not actually when she was asleep. She would wake up and feel convinced that there was a dead body in bed with her, and would lie awake for hours sweating and trembling, afraid to move or even to turn her head to dispel her fears She recognised her symptoms in later life as of the same type as those associated with the childhood experiences, and they had a close relation to emotional disasters and strains in the Forces and family life

After a frank discussion of this history, she improved very greatly and the vasovagal attacks—as I feel they must be regarded—ceased to trouble her to any extent, and finally seemed to have disappeared

No doubt there is some organic basis, but in this case the actuating mechanism appears to have been emotional

Hove, Sussex

W A BOURNE

PUBLICITY IN CANCER

SIR,—I was interested by Professor Russ's stimulating letter of March 24 Education of the public concerning cancer is a subject that has interested me since about 1930, and I organised 1200 lectures to the public for the British Empire Cancer Campaign between 1936 and 1940, when war put an end to further efforts This is a very small number compared to the total adult population , but having given many of the lectures myself, I was confirmed in my views as to the great value of such education, and that it is the only way of reducing the mortality from this disease in the immediate future

All statistical tables tell the same story of delay in diagnosis, pointed out by Professor Russ , and the latest report on international statistics of carcinoma of the cervix, which deals with 41,046 cases from 37 radiotherapeutic institutes in 11 different countries, gives 13 7% in the first stage The Americans have shown that it is possible to reduce this delay by public education In Massachusetts the delay between the date the patient first noticed a symptom and that on which medical advice was sought was reduced by education from 6 months to 3 months There is a general belief in this country that this was accomplished at the expense of producing mass cancerphobia A short visit to the U S.A last May makes me think that this idea is quite wrong, but I agree that much of the literature published would be unsuitable in this country and would do little to dispel fear, which is undoubtedly the greatest single cause for the delay on the part of the patient Such shock methods are quite unnecessary, and indeed risk defeating the end in view

There are two stock objections by those who regard cancer education as undesirable (1) that it will increase apprehension and fear , (2) that it will flood the surgeries of the G P s with people who have no symptoms I know from my experience of lecturing to the laity that Emerson was right when he said " Knowledge is the antidote to fear "

How then can cancer education be carried out ? Under the 1946 Act the local authorities are responsible for health education , but I am convinced that cancer education is not possible without first rousing the enthusiasm of the public itself, and getting its cooperation The following steps for a cancer campaign are suggested (1) to get the good will of the local medical officer of health, the local authorities, the local branch of the British Medical Association, and the regional hospital board , (2) to persuade the mayor of the town to call a meeting of representatives of the local voluntary organisations—e g , Red Cross, W V S , women's institutes, town's women's guild, rotary, inner wheel—in order to form a local cancer education committee The duties of this committee would be to organise lectures, to distribute

HEIGHTENED PERCEPTION AFTER E C T

SIR,—I have recently become interested in an unusual phenomenon following electroconvulsive therapy (E C T)

A man, admitted to hospital because of melancholia with suicidal tendencies, was given a short course of E C T in the hope of relieving his symptoms The convulsions were followed by a period of confusion which lasted about an hour This phase was constantly succeeded by a transient phase of increased awareness of the environment, lasting some six hours

He described his feelings during this time in the following words 'Everything becomes more vivid and seems to take on a bolder outline The sky buildings and even women appear more beautiful All colours are intensified, black objects increase in blackness, and red ones become more red I am conscious of a delight in life which I have not experienced for a long time Knowing that it is temporary, I can thoroughly enjoy this period One can go to the heights of Mont Blanc but one cannot remain there! Soon I drift back to my usual state of mild depression."

Another patient, suffering from an anxiety state with depressive features, claimed that a remarkable improvement in his colour vision had followed a short course of E C T

The general increase in visual acuity is somewhat reminiscent of the effect produced by the sudden relief of cerebral anoxia It can be argued that removal of depression, with its inhibiting effects, explains the augmented perception However Lhermitte and Parcheminey[1] and others have described hallucinosis following electro shock, which suggests a positive increase in activity by the sensory cortex

Basingstoke Hants J TODD

ORGANIC HYPERINSULINISM TREATED WITH ALLOXAN

SIR,—The article of Feb 24 by Dr Gilchrist and Dr Lynch is worthy of note, because the level of the serum citric acid in the case described is the highest I have ever heard of—i e, about 20 times normal This is all the more remarkable in a patient with hypoglycæmia, because I can confirm Dr Weil Malherbe's observation that the serum citrate level decreases in artificial hypoglycæmia The urinary excretion of citric acid is said to be excessive, but it must be regarded as only moderately increased as compared with the serum citric acid I have observed greater urinary excretion of citric acid per 24 hours in Addison's disease

Unless the test was influenced by pathologically increased levels of other blood constituents, it would seem reasonable to suppose the high citric acid level to be primarily of interest in explaining the pathogenesis It cannot be proved with certainty that the condition was one of hyperinsulinism It would be very remarkable if two such rare diseases as hyperplasia of the islets of Langerhans and primary liver cell carcinoma were to occur simultaneously The picture resembles rather that described in spontaneous hypoglycæmia as due to hepatic disease, and in very rare cases to liver cancer, but without pancreatic involvement The decrease in the amount of liver tissue has not always been regarded as sufficient to explain hypoglycæmia or the consumption of the large quantity of glucose that had to be administered to keep the patient alive In such cases the condition has been explained as a secondary hyperfunction of the islets of Langerhans, this must, of course, be regarded as purely hypothetical The possibility of changed metabolism of the large tumour masses and consequent increased consumption of glucose, together with decreased storage capacity of the liver, has also been suggested In the case reported the markedly increased serum citric acid might indicate such abnormal carbohydrate metabolism Reports of the citric acid metabolism in similar cases would be of interest Such high figures as 53 3 mg per 100 ml have hitherto been recorded only in animal experiments I have measured such levels in rabbits after the administration of guanidine or 'Synthalin', and Peters et al have reported similar levels in rats, guineapigs, and pigeons medicated with fluoroacetate

ORGANIC CHEMISTRY

SIR,—Your review last year[1] of my book[2] includes the comment "Scottish readers will be horrified to read that whisky is made from maize or rye, neither of which is used in the production of 'Scotch'" I should like to point out that in the U S.A whisky is made almostly exclusively from maize and rye and not, as in Scotland, from barley Your review also remarks on the neglect in my book of a description of the energetic aspects of alcoholic fermentation, including the rôle and production of A T P This problem which has long been under investigation, involves physiological chemistry, and discussion of it has no place in a textbook of organic chemistry

Chemical Institute
University of Zürich P KARRER

CATION-EXCHANGE RESINS

SIR,—We have read with interest Mr Morton's article of April 14

As far as is known, the ion exchanges of these resins are governed by the law of mass action According to Kressman and Kitchener[3] the exchange of sodium and hydrogen ions is governed by the relation

$$\frac{C_{H}}{C_{Na}} \quad \frac{C_{Na\,res}}{C_{H\,res}} = K_{H/Na}$$

where C_H and C_{Na} are the concentrations of hydrogen and sodium ions in the solution in m eq per litre, $C_{Na\,res}$ and $C_{H\,res}$ are the amounts (in m eq) of sodium and hydrogen ion per g of resin, and $K_{H/Na}$ is the exchange equilibrium constant The corresponding equation for calcium and hydrogen ions is

$$\frac{(C_{H})^2}{C_{Ca}} \cdot \frac{C_{Ca\,res}}{(C_{H\,res})^2} = K_{H/Ca}$$

Mr Morton's results do not disagree with this view For instance, in the second experiment quoted in his article, 1 g quantities of 'Zeo Karb' were allowed to react with different volumes of the same solution of sodium chloride from the results given the value of $K_{H/Na}$ calculated for the first tube is 3 30 and for the sixth tube 3 37 The agreement is excellent

Our own preliminary investigations suggest that, employing the technique of Kressman and Kitchener, 1 g of zeo karb 225/H has a capacity of 5 0 m eq and that the exchange equilibrium constant with sodium ($K_{H/Na}$) is 1 8 These results are calculated for dry resin, but air dried resin was used in the experiments and its moisture content, determined by drying at 100–120°C for 5 hours, was found to be 31%

Mr Morton's deduction that 1 g of resin equilibrated with a solution containing 6 m eq of sodium ion would be saturated with sodium is probably wrong, on the basis of his own figures it seems likely that about 86% saturation would be achieved The relation between the initial amount of sodium ion in the solution and the percentage saturation with sodium of the resin at equilibrium is a parabola Similarly 1 g of resin in presence of 0 7 m eq of sodium would have a "percentage efficiency ratio" of about 91%, and not 100% as stated

Histologically many caruncles consist of masses of granulation tissue Such a lesion, though obviously not neoplastic, cannot be described as prolapsed mucosa We believe therefore that the clinical term "caruncle" is no more misleading than the term "polyp," which is used to describe a variety of pathological lesions

The important fact emphasised by Mr Campbell Begg is that the condition of *true* erosion, although by no means rare, is not a common lesion

COMBINED ABDOMINO-VAGINAL HYSTERECTOMY

SIR,—Mr Howkins, in his article last week on the above operation, mentions that some surgeons believe it worth leaving some portion of the vagina This has obviously to be considered in operating on the younger age groups Further, the slow healing of the cavity left by removal of the vagina, with its inevitable infection and continuous discharge requiring constant attention for up to six months, must be distressing to the patient

Might not this unpleasant (though temporary) complication be avoided by combining the radical surgical removal described by Mr Howkins, with all its advantages, with the relatively simple reconstruction of the vagina popularised by Sir Archibald McIndoe ? This would add little, if any, time to the operation, since the vaginal dissection is completed before the abdominal closure starts, and the reconstruction is a short procedure It is quite possible to cut the Thiersch graft from the thigh, without removing the patient's legs from the Lloyd Davies supports The skin is then inserted into the cavity either on a preformed acrylic mould or on a gutta percha mould, which is easily made at the time of operation

If hæmostasis has been obtained, and the walls of the cavity are reasonably smooth, healing should be sound in 10–14 days If the grafting were not completely successful, then there would be delayed healing, which would not be comparable to that of a granulating cavity It should be noted that a Thiersch graft has a high resistance to infection

In selected cases the addition of the reconstruction is, I am sure, a refinement worth considering

Odstock Hospital Salisbury J ELLSWORTH LAING

TUBERCULIN SENSITIVITY IN HOSPITAL CHILDREN

SIR,—Dr Lunn's article of Feb 17 is a most valuable contribution to an important problem Only large scale investigations of this kind will provide a scientific basis for tuberculosis control programmes, with or without B C G In view of the importance of this investigation, however, I wish to submit that the percentages reported in table I and II are erroneous

The calculation of the percentage of positive reactors (1071) was based on the total admissions (7555) and reported as 14 7% This would only be true if all "results not available" were negative However, as "results not available" will probably show the same incidence of positive and negative reactors the total of "results not available" (1309) should be deducted from the total admissions (7555 – 1309 = 6246), and the positives (1071) should be related to the corrected figure of admissions (6246) This will give 17 1% positive instead of 14 7% The same correction will have to apply to the other percentages listed in tables I and II

Almirante Panama GUSTAV ENGLER

*** We have shown this letter to Dr Lunn, who replies as follows

"The point made by Dr Engler is important, and was not overlooked. Of the children for whom results of Mantoux tests were not available 1074 (82%) were under one year of age, and indeed, as was mentioned in the paper, 890 (83%) of these were under three months The incidence rate of positive reactors from birth to one year is very low (2 3% in table II, or 3 4% using the correction suggested by Dr Engler) It seemed, therefore, more appropriate to use the total number of admissions rather than the total number of Mantoux tests done as the basis for the calculation of percentage sensitivity rates"

THE ECONOMIC VALUE OF THE DOCTOR

SIR,—The letter from Dr Hughes (April 14), in which I regret to note that he seems to belittle the value of "prevention" in a health service, confirms what has been apparent for many a day—namely, that the word "health" by itself fails to convey to the hearer all that it connotes For clarity and simplicity, and to avoid misunderstanding, two words seem to be needed when we discuss health matters, because health, as the word is used today, has two main and distinct aspects—a maintenance of health or prevention of disease side, and a healing side

"Hygiene" is sometimes used for the first of these aspects, but it is an unsatisfactory word, and the Army medical authorities, in their search for a better word, have recently substituted the term "Army health" for hygiene This is an improvement, certainly, but does not quite meet the difficulty so far as civil affairs are concerned

The average individual comes into the world healthy, and what the various public health and Army health and other "preventative" workers are trying to do is to keep him healthy It is the "maintenance of health" they are mostly concerned with, this seems a better term than "prevention of disease" Disease to the average healthy person is something that is unlikely, he hopes, to happen to him The maintenance of health, on the other hand, is a personal matter, it is something of which every healthy individual understands the value, and in which he is interested If therefore we want to have good cooperation from the public, let us talk in future not so much of the prevention of disease, but rather of the maintenance of health

The National Health Service is, I feel, misnamed. It should surely be called the "National Back to Health Service"! Is that not what it principally is? The doctor whom Dr Hughes has in mind is not primarily concerned with maintaining health, for he is seldom consulted by the healthy individual, his job is, in the main, to treat the sick person, and help him to regain that healthy level from which he has fallen

To differentiate between these two aspects, two new words are needed Any suggestions?

Bad Salzuflen Germany

W STRELLEY MARTIN

TRANSPARENT FILM ENVELOPES FOR A SYRINGE SERVICE

SIR,—I read with great interest the article by Dr McCartney (March 3) Before the article appeared we had been testing these envelopes with a view to using them in the syringe service of this hospital, to overcome the shortage of glass tubes

We found that after sterilisation the syringes were sometimes non sterile, and we were at a loss to understand this On minutely examining the envelopes we found that small cracks had appeared which were not readily discernible to the naked eye It was thus felt that this was not an ideal way of packing syringes for sterilisation since handling in the wards and departments might render them non sterile, even though the envelope appeared intact These minute cracks seem to be due to slight brittleness of the envelope after sterilisation, despite the fact that the envelopes were not touched for a few hours after being sterilised

EVELYN P BUTTON

WALTER PAGEL

HYPERCALCÆMIC URÆMIA WITH NEPHROCALCINOSIS

SIR,—In their article last week Dr Fulton and Dr Paget reported a case of nephrocalcinosis and uræmia which they ascribe to hypercalcæmia resulting from carcinomatosis of bone As the patient had an alkalosis, which is known to cause uræmia and nephrocalcinosis, it seems unnecessary to bring in the carcinomatosis and hypercalcæmia except as secondary factors, and it may be presumed that their other patients with bone secondaries did not develop hypercalcæmia and nephrocalcinosis because they were not alkalotic

Dr Fulton and Dr Paget do not seem to have taken the alkalosis very seriously, for it actually became much worse while the patient was in hospital, and there is no mention of any attempt to correct it before the patient was submitted to operation It would be interesting to know why the alkalosis became worse, for the patient was apparently not vomiting, and in any case is said to have had an achlorhydria

THE "CITROVORUM FACTOR"

The American Cyanamid Company, referring to our leading article of March 17, inform us that the synthesis and isolation of a pure substance with the biological properties of the citrovorum factor were first described by research workers of the company's Lederle Laboratories and Calco Chemical divisions [1]

Parliament

Mr Bevan's Statement

IN making his statement, in the House of Commons on April 23 on his resignation from office as Minister of Labour, Mr ANEURIN BEVAN said that the charges on spectacles and dentures might be called a triviality, but a triviality had been known to start an avalanche The Chancellor of the Exchequer this year proposed to reduce health expenditure by £13 million out of the budget total of £4000 million What would happen next year? Or are you next year," Mr Bevan asked, "going to take your stand on the upper denture? The lower half apparently does not matter, but the top half is sacrosanct" The Chancellor of the Exchequer, Mr Bevan continued, was putting a financial ceiling on the health service With rising prices the health service was squeezed between that artificial figure and rising prices What was to be squeezed out next year? Was it the upper half? When that had been squeezed out and the same principle held good, what did you squeeze out the year after? Prescriptions? Hospital charges? Where did you stop?

Mr Bevan said he had been accused of having agreed to a charge on prescriptions That showed the danger of compromise Because if it was pleaded against him that he agreed to the modification of the health service, then what would be pleaded against his right hon friends next year, and indeed what answer would they have if the vandals opposite came in? The health service would be like Lavinia—all the limbs cut off and eventually her tongue cut out, too After all, the service was something of which we were all very proud Even the Opposition were beginning to be proud of it It only had to last a few more years to become a part of our traditions, and then the traditionalists would claim the credit for all of it

Why had the cut been made? With an over-all surplus of over £220 million and a conventional surplus of £39 million the Chancellor could not plead that he had to have the £13 million. That was the arithmetic of bedlam Surely he could not say that his arithmetic was so precise that he must have £13 million, when last year the Treasury were £247 million out. Had the American Medical Association, Mr Bevan asked, succeeded in doing what the British Medical Association failed to do?

Mr Bevan said he had been accused of agreeing to the prescription charge, but he pointed out, he knew that charge would never be made, for it was impracticable And in fact it never was made A proposed reduction of 25,000 on the housing programme had also never been made At that time he had to use what everybody called bad tactics He had had to manœuvre, but he saved the 25 000 houses and the prescription charge We had gone a long way against great difficulties "Do not let us change direction now," Mr Bevan urged "Let us make it clear to the rest of the world that we stand where we stood, that we are not going to allow ourselves to be diverted from our path by the exigencies of the immediate situation We shall do what is necessary to defend ourselves—defend ourselves by arms, and not only with arms but with the spiritual resources of our people"

National Health Service Bill, 1951

This Bill, which was read in the House of Commons for the first time on April 17, authorises the charges for dentures and spectacles announced by the Chancellor in his budget speech The Bill, which applies to England, Wales, and Scotland, also empowers the Minister of Health and the Secretary of State for Scotland to send patients with respiratory tuberculosis abroad for treatment

The charges for false teeth and glasses will be made to patients who obtain these aids under the "family-practitioner service" and to hospital outpatients, but no charge will be made to hospital inpatients. People who cannot afford to pay the charges will be able to apply to the National Assistance Board for help even though they are in full employment No charge will be made for sight tests or for dental treatment The amounts of the charges are specified in the Bill but they may be varied by order in council, subject to an affirmative resolution of both Houses. The charges cover about half the cost to the Exchequer and are as follow

Dentures —Full upper and lower £4 5*s* Single dentures 1–3 teeth £2 4–8 teeth £2 5*s*, 9 teeth or over £2 10*s*

Spectacles —£1 a pair plus the cost of the frames, which ranges from 3*s* 4*d* to 15*s* 1*d* Children's glasses in the standard type of frame will still be free of charge

The charges will be paid direct by the patient to the dentist or optician under the family-practitioner services, or to the hospital authorities and the fees payable by the executive council to the dentist or optician will be correspondingly reduced

Mr HILARY MARQUAND Minister of Health, moving the second reading on Tuesday, said that charges for dentures and spectacles must not be regarded as permanent features of the N H S In the next few difficult years he hoped to expand hospital services, including the hospital treatment of tuberculosis More money was needed than the Chancellor could see his way to provide, and the measures taken to get that money were not an attack on the service" Dr CHARLES HILL remarked that uncontrolled rise in expenditure on the N H S might spell ruin for other social services

The second reading was agreed to without a division

[1] Brockman, J A jun Roth B Broquist H P Hultquist M E. Smith J M jun. Fahrenbach M J Cosulich D B Parker R P Stokstad E L R. Jukes T H *J Amer chem. Soc.* 1950 72 4325

In the second paragraph of the article the effect of ion concentration upon the displacement of calcium from the resin by sodium and upon the reverse process is described This effect can be deduced from the relations given above The word " affinity " is confusing, and data are best discussed in terms of the exchange equilibrium constant

Magnesium trisilicate is known to release magnesium ions in the presence of acid, and Mr Morton's finding of a reduction in the amount of sodium ion removed by the resin when magnesium trisilicate is added to the system is to be expected The therapeutic value of magnesium trisilicate would be doubtful, because the " acidosis " is due to loss of base into the resin rather than to the associated release of hydrogen ions

We agree that patients treated with ion exchange resins need to be very carefully controlled It is our experience that the serum sodium determination is important

IAIN MACINTYRE
Sheffield ARTHUR JORDAN

THEORY OF CEREBRAL LOCALISATION

SIR,—In the light of Dr Gooddy's retort (March 31), may I add a little to my letter of March 17 ?

It is probably true that of recent years some neurologists have been at times somewhat rigid in their exegesis of localisation But this inflexibility has been largely in the matter of patterns of representation within the motor strip alone, and not so much in that of cerebral functional topography as a whole Thus argument has centred predominantly on the problem of the cortical representation of movements or of muscles Whilst the American school of neurologists has claimed direct muscular representation, in this country the opposite opinion has been held , and the lately published researches of Liddell and Phillips,[1] which at last confirm from the laboratory the view of cortical thresholds of excitability so brilliantly deduced by Walshe[2] from clinical observation alone, provide further evidence in support of the traditional English view

However, it may be questioned at this point whether the argument between the two camps is not really an artificial one—whether, that is, the two hypotheses are truly alternative and incompatible with one another It may be held that they are not absolutely discordant, and that therefore both views may possibly be right For my own part, I do not see any valid a priori obstacle to making such an assumption, and hence to thinking that both movements and muscles are simultaneously represented in the cortex It may be objected by some that such an idea is counter to reason, but then Nature is not overindulgent in fitting her behaviour to accord with the principles of logic It is relevant to note that current physical thought has been compelled to accept two interpretations at once of the nature of light that it has a continuous wave form, and that it also and at the same time consists in discontinuous packets of energy—theories which, judged at face value, would appear mutually exclusive

Still, although discussion of the details of physiological organisation within the motor area has bulked large in neurological literature, it must not be taken to make up the whole body of ideas about cerebral localisation It should be remembered that for more than twenty years now, Lashley[3] has been insisting on the functional equipotentiality of nervous tissue and he has accumulated a formidable body of evidence in support of his view In essence his work is also an experimental validation of Hughlings Jackson's older and virtually identical conception, that every part of the body is represented everywhere in the nervous system In the last few years the discovery[4] of secondary, and even tertiary, loci of motor and sensory representation in the cerebral cortex, and of complicated cerebellar representations of the body (derived both from the cerebrum and from the spinal cord) and even of the viscera, have provided, from a different angle, implicit confirmation of the Jacksonian concept, though so far as I am aware no one has yet drawn specific attention to this fact

I submit once again that, in face of all the evidence, it is vain and nugatory to assert that theories of cerebral localisation need overhauling simply in the light of the results of human hemispherectomy Nevertheless, the results of hemispherectomy do suggest the need for critical reassessment of Jackson's notion that destructive lesions cause only negative symptoms This is doubtless true for the outcome of planned ablations of nervous substance, whether therapeutic or experimental It is evidently not necessarily true where the destruction results from natural causes As a speculation it may be suggested that it fails where the lesion is patchy, so that islands of more or less normal cells are left in action scattered amidst functionless wastes of tissue, but that it holds good where there is uniform dissolution throughout an area,

Birmingham MICHAEL JEFFERSON

THEN AND NOW

SIR,—Discoveries are often " in the air " before they are made Fertile ideas and fortunate speculation have, not infrequently, prepared the soil for them This topic is touched on in the most interesting paper (April 14) by Dr Keevil and Mr Payne, who describe what appears to be a speculative anticipation of the circulatory motion of the blood by Reyna in 1546

I have lately drawn attention to a similar instance—namely, the assertion by Giordano Bruno in 1591, on philosophical grounds, that the blood " moves continually and very rapidly in a circle "[5] This seems to support the view that Reyna, too, expressed a philosophical concept which, at his time as well as later on, was " in the air " I have tried to trace it to the revival of certain Aristotelian and Neo Platonic theories in the Renaissance[6]

How much attention should we pay to such a speculative vision which anticipated a scientific discovery ? Today scientists and doctors who look back on these speculative anticipations may feel that they have but little interest and value, and be interested only by scientific evidence based on observational material—in other words, the " Harveian method "[7] The historian, however, not content with the extraction of " relevant " data, will take a larger view Harvey was inclined to accept a " philosophy of circles," as initiated by Aristotle , to Harvey blood circulation was one instance of a general cosmic law of circles, periodical processes, and circular patterns with reversion to the point of departure[8] , and in this light the " philosophy of circles " before Harvey's time is of great historical interest, however remote it may seem from his scientific (i e , quantitative) studies The speculations about circulation, by Reyna, Bruno, and probably others of their time, belong to the " Verities yet in their Chaos," as Harvey's own speculations have been aptly designated[9]

Great Britain for the Colonial Medical Service , and how many scholarships for medical training had been awarded during the last three years by the governments of Kenya and Sierra Leone —Mr JAMES GRIFFITHS replied No hospitals or dispensaries have been closed in Kenya but I regret that in February, 1951, staff shortages made it necessary temporarily to close 2 hospitals in Sierra Leone Posts in the Colonial Medical Service are widely advertised and African medical students are encouraged to apply for them. During the last three years, the Kenya government has awarded 17 scholarships for medical training and has also paid £21,000 to Makerere College for the training of African medical officers The Sierra Leone government has made 7 awards and 2 awards have been made to Sierra Leone students from the central allocation of colonial development and welfare funds.

Obituary

FRIEDRICH KARL KLEINE

M.D Halle

Dr Friedrich Karl Kleine, who has died in Johannesburg at the age of 81, had won international renown for his work on tropical medicine, especially on the life-cycle of the trypanosome. His friends and collaborators also respected his integrity, his dogged character which overcame all difficulties, his loyalty, and his delightful puckish sense of humour

Kleine studied medicine in Halle, till in 1900 he became assistant to Robert Koch, then at the height of his fame, at the Institute for Infectious Diseases in Berlin In 1902 he accompanied his chief to Southern Rhodesia to investigate African coast fever of cattle In these animals he found two species of parasite, the smaller of which, *Theileria kochi*, proved to be new to science He also did useful work on the immunisation of horses and mules against horse-sickness In 1906 he became interested in the piroplasma of dogs, and he was one of the first to elucidate its life-history But soon his interest turned to trypanosomiasis of man and animals, a subject to which he devoted the rest of his life

[illegible]

Fired by the work of David Bruce, Dutton, and others he was the first in 1909 to work out the life-cycle of the trypanosome *T brucei* in the body of the tsetse fly and to show conclusively that the infective forms were injected by the insect with the salivary secretions, the whole cycle occupying some three weeks. These observations were the starting-point of much new work on the epidemiology of trypanosome diseases.

Early in 1914 Kleine was in the Cameroons investigating sleeping-sickness, and he was soon engulfed in the first world war as head of the German medical services there

Nevertheless he continued his researches and he was able to confirm Leiper's discovery (1913) of the life-history of *Loa loa* in chrysops. At the end of the war he returned to the Robert Koch Institute in Berlin, but he was soon off again to his beloved Africa where in 1921 he tested the properties of the new Bayer 205' (now known as suramin) as the most effective drug in human trypanosomiasis. On this expedition he was accompanied by Fräulein H Ockelmann, an assistant in the institute who later became his wife and who was his co-worker during the last 30 years of his life

Returning to Berlin in 1923 he became interested in the health section of the League of Nations, and in 1926 he was appointed the German delegate The same year he investigated in Uganda problems of human immunity against trypanosomes in natives living in a focus of sleeping sickness He also devised experiments to differentiate *T gambiense* from *T rhodesiense* After a short period of recuperation in Europe, in 1929, he investigated the virulence of *T rhodesiense* in Tanganyika During this period he and his wife underwent very considerable hardships while exploring undeveloped country

In 1933 he became president of the Robert Koch Institute in Berlin, but three years later he spent another fruitful year at the Veterinary Research Institute in Onderstepoort in Pretoria studying foot-and-mouth disease in cattle and big game His last journey before the second world war took him in 1938 to Tabora, Tanganyika, where he investigated the rôle of cattle as reservoir hosts of *T rhodesiense* He celebrated his 70th birthday on Fernando Po, drawing up a report on the island's campaign against trypanosomiasis.

During the late war Kleine suffered from privations and persecution His home in Berlin was destroyed and his only son died of wounds After the fall of Hitler and at his advanced age he undertook single-handed the task of reorganising the tropical section of the Robert Koch Institute, visiting the department daily But the lure of Africa proved too strong for him, and at the age of 78 he and his wife travelled to Johannesburg where under the kindly care of old friends Kleine passed his last days

P H. M-B

JOHN GAY FRENCH

M S Lond , F.R C.S

MR Gay French, consulting ear, nose, and throat surgeon to the Royal Free Hospital and formerly senior surgeon to the ear, nose, and throat department of the Royal Northern Hospital, died on April 13 at the age of 79

He was born at Mymensing in Bengal, the youngest son of Lieut -Colonel J Gay French, F.R C S , I.M.S , and he was educated at Trinity College, Dublin, and the University of London. He obtained an open entrance scholarship to St Mary's Hospital, and after graduating M.B in 1902, he held house-appointments there, and at St Bartholomew's Hospital, Great Ormond Street Hospital, and the Golden Square Hospital for Diseases of the Throat and Ear In 1906 he was appointed to the staff of the Royal Northern Hospital and in the same year he took his B.S with honours The following year he became assistant surgeon at the Central London Throat and Ear Hospital and he also obtained his M.S degree and the F R C.S He was thus firmly established in his specialty when he joined the staff of the Royal Free Hospital and became lecturer in diseases of the ear, nose and throat at the London School of Medicine for Women.

Mr Gay French was also for many years on the staff of the Royal Masonic Hospital and he was for some time consulting specialist to the War Office His published work included papers on middle-ear deafness, and he contributed the chapter on diseases of the pharynx and larynx to the *Dictionary of Practical Medicine* (1923)

T J H writes Those who knew him well appreciated his kindly nature, his ready sympathy and encouragement to his younger colleagues, and his absolute integrity As chairman of the medical committee of the Royal Free Hospital he showed balanced judgment impartiality, and sincere regard for the best interests of the hospital He had a fierce presence and a somewhat gruff manner, but he was beloved by colleagues, students, nursing staff, and patients, who were quick to discern the real man, which his rather austere bearing could not conceal He was a good raconteur with a great sense of dry humour He enjoyed life and even when family losses might have embittered a lesser man he kept a brave, cheerful front, which, if possible, increased the admiration and affection in which he was held "

He married Elinor May Pipe-Wolferstan in 1911 Their three sons predeceased their father

Prof K D WILKINSON

T L H writes ' For thirty years the friendship of Kenneth Wilkinson has been for me an exhilarating and delightful experience He was a man with an exuberant vitality and self assurance which at first contact were almost overwhelming Life for him was an exciting adventure to be savoured fully and vigorously and he liked to share his experience with his friends His sense of humour was of the keenest and as a raconteur he had few rivals, and he could talk fluently, accurately, and humorously in many dialects No-one who heard it will forget his presidential address on this subject given some years ago to the Birmingham Graduates Club 'The Wilk, as he was affectionately called, was indeed a fellow of infinite jest and most excellent fancy

The Care of Old People

In the House of Lords on April 18, Lord SALTOUN moved "That this House regards with sympathy and concern the difficulties of old people and calls upon the Government to secure the greatest measure of coordination between the health services and other social services with a view to ensuring that adequate personal service and attention are available to such old people" Under the new system, he said, these people were nobody's care In the past six months 17 cases had been reported in the press of old people who were found dead in varying conditions of horror He refused to accept these conditions as normal Despite the efforts of all concerned the machinery of the health and social services did not work well, and some reform seemed to be imperative Often there were reports of elderly patients being refused admission to hospital, and a system in which a conscientious public servant had to resort to the device of refusing to sign certificates if old people died, and threatening to cite hospital officials at a subsequent inquest, was in Lord Saltoun's view self condemned In six months he had collected 11 cases where hospitals had refused to admit elderly persons To remedy the situation Lord Saltoun suggested the appointment of a local officer at borough or district level with responsibility for knowing all the cases in his area and with power to arrange for treatment in private homes at rates not exceeding the cost of county homes He should act as a focal point between county, borough, hospital, and Assistance Board After all, Lord Saltoun pointed out, the sensitive part of an elephant's trunk is at the tip

Lord KERSHAW, Lord in Waiting, said that though the Government were prepared to accept the motion, they did not accept many of Lord Saltoun's conclusions National Assistance officers were in touch with far more people than the former relieving officers could be It was absurd to pretend that the change-over from poor relief to supplementary pensions was not welcomed by aged people Of the 1,000,000 old people who applied for supplementary pensions when the National Assistance Board began, 700,000 were people who had preferred to make do without that relief, although many of them must have been in great distress There were now 600 county and local welfare committees at work and more were being continuously formed Since the end of the war 300 local-authority homes accommodating old people had been opened in England and Wales, and another 300 were in course of preparation Hospital beds were a problem that nearly defied solution, and Lord Kershaw agreed that there was need for closer coöperation between the various agencies dealing with old people A special committee of the Central Health Services Council would shortly report on this matter

Lord AMULREE agreed that people were trying hard to make this new social plan a success, but he supported Lord Saltoun's suggestion that it would be an advantage if someone was officially charged with the duty of finding out the conditions among the sick and infirm poor Prompt admission to hospital would nearly always ensure prompt discharge, that was as true for old people as it was for the young A short spell in hospital at the right time might often lead to many years of comparative health at home Though it was impossible to provide any more hospital beds at present, he suggested that the number of beds now available was probably sufficient for the needs of the aged population if they were properly used In some of the hospitals where the old and chronic sick patient was properly treated it had been possible in the course of a few years to cut down the number of beds to a third or even a quarter of the previous total and yet deal with the same or a bigger population In five or ten years' time Lord Amulree thought it would be unnecessary to provide more beds even for a vastly older population But while beds were still in short supply it had been suggested that, subject to a medical certificate, there should be compulsory admission to a hospital for a short time Lord Amulree thought there was something to be said for the proposal, but there should also, he suggested, be compulsory admission to an institution or home We could not place the whole burden on the hospitals, or they would get clogged up There should also be means of compelling younger people to look after their parents after they left hospital

Dangerous Drugs Bill

In the House of Lords on April 17 the LORD CHANCELLOR introduced this Bill, which is a measure to consolidate the Dangerous Drugs Acts 1920 to 1950, and section 28 of the Pharmacy and Poisons Act 1933

QUESTION TIME

Hospital Accommodation for Chronic Sick

Miss IRENE WARD asked the Minister of Health whether, in view of the shortage of beds for the chronic sick in the country, he would consider making it a statutory obligation on the regional hospital boards to accept cases recommended by medical officers of health as in need of care and attention. —Mr H A MARQUAND replied No, Sir

Pulmonary Tuberculosis among Foreign Workers

Mr WILLIAM TAYLOR asked the Minister whether he was aware of the prevalence of pulmonary tuberculosis amongst foreign workers in Bradford, and whether he would now cause a much stricter medical examination to be made of foreign workers entering this country by the immigration authorities —Mr MARQUAND replied Notifications of respiratory tuberculosis among foreign workers in Bradford in the years 1947 to 1950 were respectively 0, 6, 15, and 26 The last three figures represented 2 9, 5 4, and 10 4% of the total notifications in that city Over half the cases were European volunteer workers, who are medically examined for tuberculosis before being brought to this country, and most of the others were ex prisoners of war or members of the Polish armed forces I am examining with other Ministers concerned whether anything more can be done to prevent immigration of foreign workers with tuberculosis.

Charges for N H S Dentures and Spectacles

Commander A H P NOBLE asked the Minister what would have been the total saving if charge for dentures and spectacles had been made from the start of the National Health Service—Mr MARQUAND replied An exact calculation cannot be made, but I estimate that the saving in England and Wales would have been of the order of £50 million.

Patients Discharged from Broadmoor

In answer to a question Mr CHUTER EDE, Home Secretary, stated that in the ten years up to the end of 1950 the number of patients discharged from Broadmoor Institution was 148 males and 61 females, giving a total of 209

Morphia for Railway Accidents

Commander J F W MAITLAND asked the Minister of Transport whether he would introduce legislation to enable a supply of morphia to be included among the drugs and appliances kept in railway trains for service in case of accident —Mr ALFRED BARNES replied I could not recommend such a step If supplies of this dangerous drug were kept in railway trains, the risks of its misuse would in my view outweigh any possible advantages Experience has shown that qualified medical staff, with supplies of the necessary drugs, are almost invariably on the scene of an accident quickly

Cope Reports

Mr IAN MIKARDO asked the Minister of Health if he would make a statement upon the reports of the committees which, under the chairmanship of Mr Zachary Cope, considered the supply, demand, training, and qualification of medical auxiliaries in the National Health Service —Mr MARQUAND replied The Secretary of State for Scotland and I have now been able to study the reports, and we should like to pay tribute to the thoroughness and value of the investigation made by Mr Cope and the members of the committee The recommendations of registration made in the majority reports, which would require legislation, will now be taken by us as the basis of discussions with the appropriate organisations Meanwhile, pending the establishment of official registration machinery, we propose to apply the recommended qualifications to new applicants for posts in the National Health Service

Medical Services in the Colonies

Mr JAMES JOHNSON asked the Secretary of State for the Colonies how many hospitals and dispensaries had been closed down in Kenya and Sierra Leone through shortage of doctors, what steps were being taken to recruit African doctors in

PROTECTION FROM NOISE

The excessive noise to which many industrial workers are exposed often reduces their efficiency and occasionally causes permanent deafness Plugging the ears with cotton wool does not reduce the noise effectively, while ear plugs commonly preclude conversation. New plastic ear plugs, the 'Sonex ear defenders,' are said by the makers to reduce noise to one thousandth of the original intensity while still allowing normal speech to be heard These ear plugs are manufactured by Amplivox Ltd , 2, Bentinck Street, London, W 1

University of London

Dr A Fessard, professor of neurophysiology at the Collège de France, Paris, will deliver three lectures at University College, Gower Street, W C 1, at 5 30 P M on May 16, 21, and 22 He will speak on Comparative Electrophysiology

On Friday, May 18, at 5 30 P.M , at University College, Gower Street, W C 1, Prof D Bovet, of the Instituto Superiore di Sanita, Rome, will give a lecture on Natural and Synthetic Sympatholytic Drugs and their Structural Relationship with Sympathomimetic Substances

University of Sydney

The university invites applications for a senior medical research fellowship (£A900–1250) and for a junior medical research fellowship (£A800–1000) Further particulars will be found in our advertisement columns

Gresham College

On Monday, April 30, at 5 30 P M , at the college, Basinghall Street, London, E C 2, Prof Hamilton Hartridge, F R S , will give the first of four lectures on the Circulation of the Blood Further particulars will be found in our advertisement columns

Institute of Dermatology

From May 1 to June 22 at this institute, St John s Hospital, Lisle Street, London, W C 2, there will be a course of lectures on general dermatology and of lecture demonstrations on pathology, including medical mycology Clinical demonstrations for postgraduates will also be held on Fridays at 5 P M

Scottish Pneumoconiosis Unit

On April 21 Miss Margaret Herbison, M.P , opened the first Scottish pneumoconiosis unit at Bangour Hospital, West Lothian

Royal Appointments

Brigadier W R D Hamilton, late R A M C , has been appointed as honorary physician to the King in place of Major General John Bennet, who has retired, and Major-General R D Cameron, late R A M C , director of medical services, British Army of the Rhine, honorary surgeon in succession to Major General W E Tyndall, who has retired

A Tudor Physician

During the Festival of Britain the Arts Council are holding a series of concerts of music by English composers at the Wigmore Hall. The programme of the concert on the early Tudor period, on May 30, includes a motet, discovered this year in the library of the Royal College of Physicians of London, by Dr Robert Fayrfax. It is entitled *O Johannas Beatissimus*

Isle of Man Health Services

Resolutions approving expenditure in the current year of £557,000 on health services, and of £600,000 capital expenditure on improvements and extensions to hospitals, to be spread over three years, have been passed by Tynwald, the Isle of Man parliament Introducing the estimates, Mr T C Cowin chairman of the social services board, said £43 000 would be needed to meet specialists remuneration for the current year and to discharge liabilities for past services The amount saved in four months, the beginning of October to the end of January, by the prescription charge of 6*d* said Mr Cowin, was £2183, and on the charge for containers £275 The main saving was expected from the deterrent effect Exempted from payment were 7337 children, 1648 pensioners, and 463 persons incapacitated through illness making a total of 9448

Of the £600,000 voted to the board about £75 000 had not been spent This was largely because it was not possible to complete a scheme for the remuneration of doctors for travelling or to appoint specialists

Royal Society

Those lately elected foreign members of the society include

Prof H M Evans M D who holds chairs of anatomy and biology in the University of California, for his researches in anatomy, embryology and experimental endocrinology

Prof K S Lashley PH.D who holds the chair of neuropsychology at Harvard University for his studies of the neurological basis of animal behaviour and of the factors involved in learning

R W G Wyckoff of Bethesda, Maryland, for his contributions to the study of viruses

The society invites application for a Locke fellowship (£1250 per annum) for research in experimental physiology and pharmacology Applications are also invited for two Stothert fellowships for research in medicine Further particulars of these fellowships will be found in our advertisement columns

Chelsea Clinical Society

The annual dinner of this society will be held at the South Kensington Hotel, 41, Queens Gate Terrace, S W 7, on Tuesday, May 8, at 7 30 P M

Oliver Memorial Fund

A fourth award, of the value of £50, will shortly be made from this fund to a British subject for work or services in connection with blood transfusion. Applications or suggestions should be sent before June 30 to Mr F W Mills, hon. treasurer, c/o National Provincial Bank Ltd , Holborn Circus, London, E C 1

Potassium Bromide

Notice will shortly be received by all doctors and chemists who are contractors with executive councils, advising them that sodium bromide may be dispensed in place of the potassium salt where supplies of the latter are not available to meet orders on N H S prescriptions No special endorsement of prescriptions will be required This arrangement has been agreed as a temporary measure, and no exception has been taken to it by the National Formulary Committee

Thames Pollution

The Minister of Local Government and Planning has appointed a departmental committee to consider and report on " the effects of heated and other effluents and discharges on the condition of the tidal reaches of the River Thames, both as at present and as regards to any proposed new developments in the area " Prof A J S Pippard, head of the department of civil engineering at the Imperial College of Science and Technology, has been appointed chairman Pollution of the Thames was discussed in these columns last week (p 914)

International Student Course for Social Medicine

The International Student Movement for the United Nations is holding a seminar on social medicine from May 7 to 9 at Geneva during the meeting of the World Health Assembly The speakers will include Dr Brock Chisholm, the director general of W H O , heads of W H.O 's various departments, and several national delegates to the assembly Further particulars may be had from the secretariat of I S M U.N , Villa Rigot, 1 avenue de la Paix, Geneva, Switzerland

Price's Textbook of Medicine

On April 17, on the occasion of the publication of the 8th edition of *A Textbook of the Practice of Medicine*, a dinner was held at the Athenæum with Dr F W Price as the guest of honour Mr Geoffrey Cumberlege, publisher to the University of Oxford, who was the host, stated with regret that Dr Price was retiring from the editorship He recalled that the book was first published in 1922, and noted that the sales were now divided almost equally between Great Britain and overseas He concluded by presenting to Dr Price a specially bound copy of the last edition Dr Donald Hunter who is succeeding Dr Price as editor, summarised his predecessor's achievement and spoke of the requirements of books designed to encourage interest in clinical medicine He emphasised the need for approaching all the problems of medical education with a clear vision of the end to which medicine is directed Dr Price, in responding, spoke of his regret at relinquishing the burden of editorship which he had carried for so long and alluded to those of his associates who had died The proceedings terminated with a speech by Mr G T Hollis, editor of Oxford Medical Publications, who touched on some particular aspects of the textbook, with reference to the fulfilment of its original purpose and its prospects for the future

“ But behind the scintillating façade, which he could throw off as readily as he could assume, and the shafts of wit which delighted and did not wound, was a heart as kind and generous as one could meet He was a fine physician of the older school with a special knowledge of cardiology, acquired only after a long apprenticeship in the field of general medicine His powers of observation were unusually acute and his approach to a problem a model of clinical medicine at its best He held his opinions strongly and expressed them in dogmatic and forthright assertion, and right or wrong, they were not lightly to be shaken

“ He had many interests, but he perhaps preferred the arts and crafts of man to the works of nature A good piece of machinery, a yacht under sail, a camera, old books, and good pictures—all delighted him, and his enthusiasm was infectious Whatever he undertook, teaching, writing, playing golf, he took infinite pains A most genial host, when times were propitious he entertained his friends with generous hospitality, and on these occasions he liked to show his admirable ciné films of local events and accompany with inimitable running comment

“ In his delightful family circle he was at his best, primus inter pares, and his two marriages and the children of those marriages brought him great and lasting happiness When adversity came in the form of serious illness he met it with unflinching courage He adjusted his life to meet his limitations and set to work on a task he had long had in mind, a life of William Withering and a history of the contemporary scene in Birmingham Writing did not come easily to him, but with the help of his devoted and able wife this work was published just over a year ago He worked almost to the last, teaching when he felt able, and attending and contributing to the weekly staff rounds to the great delight of his colleagues Kenneth Wilkinson was devoted to the Birmingham Medical School, and by the fine quality of his service he has earned his place as one of the greatest of her sons ”

Births, Marriages, and Deaths

BIRTHS

ARONSON —On April 20, in London the wife of Dr R. P Aronson —a daughter

CLARKE —On April 13 the wife of Dr Owen Clarke—a daughter

DACIE —On April 18 in London the wife of Dr J V Dacie—a daughter

DAVIES —On April 14 at Chester, the wife of Dr J H Davies —a son

DICK —On April 20 at Cambridge, the wife of Dr Peter Dick—a son

DOVE —On April 18 at Liverpool the wife of Dr W L Dove—a son

GRIFFITHS —On April 19 at Liverpool the wife of Dr G I T Griffiths—a daughter

JAMES —On April 17 in Boston Mass U S A the wife of Dr A H James—twin sons

KAGAN —On April 18 in London the wife of Dr R S Kagan—a daughter

Notes and News

NEW MOVE AGAINST VENEREAL DISEASE

To eradicate a contagious disease it is necessary to treat existing cases and to prevent new ones With venereal diseases the treatment of all cases is especially difficult, because reluctant patients must first be made aware of the dangers of such disease so that they will overcome their feeling of shame and fear of social disapprobation, and prevention is a complex matter which touches all aspects of community life

In this country, where these problems are shared between national and local authorities, much progress has already been made But, as Mr A J King pointed out in London last week, there is real need for a new organisation concerned with the social implications Mr King was speaking on April 17 at a meeting, convened by the Medical Society for the Study of Venereal Disease to discuss the formation of a new organisation for combating venereal disease , the meeting was attended by representatives of the Churches, the medical and nursing professions, the Armed Forces, and 28 organisations concerned with social welfare Sir Allen Daley, the chairman, paid tribute to Colonel L W Harrison as the main proponent of the proposed organisation, and remarked that venereal disease was still very much a national and international problem There were ebbs and flows of public interest , and at the moment the public did not seem greatly interested, though these diseases were a menace to the health of the country

It was finally decided that membership of the new organisation, provisionally named the British Federation Against Venereal Disease, should be open to all interested societies and people Its aims are (1) to study conditions that favour venereal infection and ways of combating these , (2) to assist bodies seeking to counter venereal disease , (3) to encourage the spread of knowledge of the facts about venereal disease , and (4) to collaborate with other national and international organisations having similar objects The secretary is Dr F R Curtis, secretary of the Medical Society for the Study of Venereal Disease

LONDON CHILDREN AT FRENCH SPA

IN 1949, and again last year, International Help for Children arranged for some London boys and girls to take a six weeks' cure at La Bourboule, in the Auvergne The 25 children were chosen by the London County Council and were all sufferers from asthma, one of the conditions in which La Bourboule specialises The possibility of sending them for a further month / this summer is under consideration, and last week accounts of the scheme and of the spa were given at a reception in London Mr Michael Lubbock, chairman of International Help for Children, said that the care given to the London children at La Bourboule (which has hitherto included free accommodation as well as free treatment) was greatly appreciated he could not speak of their physical improvement but they were transformed in spirits, and revivified M Buronfosse described the arrangements , Dr Ferreyrolles, who has practised at La Bourboule for 37 years, spoke of the indications of the spa , and Dr Henri Olivier, the medical administrator, demonstrated charts showing that bronchial spasm induced by histamine is overcome by inhaling the mineral water vaporised as an aerosol A film was shown illustrating the life and work of La Bourboule As noted in these columns eighteen months ago,[1] the spa lies at 2765 ft and has arsenical water, hot (60°C) and exceptionally radio-active Its most characteristic feature is its use by children who come for the treatment of catarrh, bronchitis (non tuberculous), asthma, anæmia, skin disorders, and debility after illness “ Children unaccompanied by their parents live in special pensions or hostels, and have a carefully regulated régime including rest periods and several hours each afternoon in a large children's park, which is at once a medical centre for physical culture and a place of happily unregulated amusement on swings and merry go rounds or playing around a stream ”

Though La Bourboule will still provide free medical care for the London children, about £30 must now be found to pay the fares and accommodation of each The address of International Help for Children is 43, Parliament Street, London, S W 1

DIAGNOSIS AND TREATMENT OF BULBAR POLIOMYELITIS *

W Howlett Kelleher
M.D N.U.I , D.P.H.
PHYSICIAN SUPERINTENDENT, WESTERN HOSPITAL, LONDON

The term "bulbar" is usually applied broadly to any clinical type of poliomyelitis resulting from lesions in any part of the brain stem, although strictly it is only applicable to poliomyelitis with a lesion in the much more limited area of the medulla oblongata

It was pointed out many years ago that, histologically, every case of poliomyelitis will show lesions in the brain Hence every case, is strictly classifiable as polioencephalitis or polioencephalomyelitis Fortunately in the majority of cases the lesions in the brain are so slight as not to produce clinical signs of encephalitis In some epidemics, however, they are sufficiently common to give rise to clinical signs in from a quarter to more than a third of all cases of poliomyelitis For example, reviewing the disease as seen in this hospital in 1947, I found that about a third of the cases had symptoms denoting a lesion of the brain stem, with or without spinal lesions

In the cerebrum lesions are rarely demonstrable, except in the motor area of the cortex In the cerebellum only a very limited area, encompassing the roof nuclei, may be attacked. The apparent immunity of these tissues seems to depend on resistance to infection and to the restriction of the advancing virus to well defined pathways

The histopathologists emphasise the rarity of cerebral lesions and attribute the spasticity occasionally seen in encephalitic types not to cerebral cortical damage but rather to activity of the virus in the brain stem Damage in the brain stem can also produce restlessness and occasional drowsiness and even coma Some, however, attach considerable importance to the rôle of cerebral hypoxia in the production of such symptoms

By and large, then, when we talk of polioencephalitis we mean the not inconsiderable group of cases with lesions of the brain stem, notably the medulla , and the present time seems appropriate for a review of our knowledge of the clinical pathology and classification of this too often distressing localisation of virus

We owe a great debt to our American colleagues for the abundant literature on bulbar poliomyelitis, largely based on quite recent experience Bower (1949), of Los Angeles, cites case records of 4774 patients treated in his hospital in 1946–48, and no less than 783 of these had bulbar lesions During the same period, in Minneapolis, Brown (1949) and his colleagues saw 318 cases of bulbar type, which represented rather less than a third of all cases of poliomyelitis observed by them

It would be misleading in any study of the attack of this virus on the brain stem to assess either the effects of the lesions or the result of treatment from a limited experience There is general agreement that both the incidence and the severity of bulbar lesions can vary in different epidemics In 1947, at the Western Hospital, although we were meeting with a higher proportion of bulbar cases, the severity of the cranial nerve lesions was much less than I had anticipated from impressions of the danger of these lesions gathered in the pre war years. In 1949 we met with a disturbingly higher proportion of dangerous forms of bulbar attack. I am probably not alone in having such experience in this country during that year

Not so long ago it was grudgingly accepted that patients with the more dangerous types of bulbar poliomyelitis would die, no matter what was done for them (All agreed that patients with lesions of the upper group of cranial nerves rarely, if ever, gave rise to any anxiety and would more or less recover in due course) In recent years, however, claims have been made for much more successful results in the treatment of those gravely ill with lesions of the brain stem, both through a better recognition of the factors producing symptoms and through a better application of the principles directed to their alleviation There are few diseases in which such rapid fluctuations in severity take place and where spontaneous recovery is so common The evaluation of such measures is very difficult, and there is no unanimity about the line to be taken

CLASSIFICATION OF TYPES

The most generally acceptable grouping is that adopted by the Minnesota Poliomyelitis Research Commission (1947) as follow

(1) The cranial nerve nuclei group
(2) The respiratory centre group
(3) The circulatory-centre group
(4) The encephalitic group

Combinations of any of these groups may be met with

LESIONS OF CRANIAL NERVE NUCLEI

The Minnesota Commission propose, for the purposes of symptomatology and therapy, a division of the cranial-nerve nuclei group into upper and lower subgroups In the upper subgroup are included the nuclei of the 3rd, 4th, 5th, 6th, 7th, and 8th cranial nerves In the lower subgroup, although all the nuclei of the 9th, 10th, 11th, and 12th cranial nerves are important, it is damage to the nucleus of the 10th nerve that gives rise to the most dangerous symptoms

Upper Subgroup

Lesions of the upper subgroup were, in my experience here, very common in the 1947 epidemic, and many of them were very slight When they occurred without spinal lesions they did not give rise to anxiety, apart from ultimate prognosis On the other hand, there were many cases with spinal lesions in which the disease was mild, with pareses rather than paralyses

Apart from nystagmus, ocular signs and symptoms were uncommon, slight, and usually of brief duration We met with one example of choked disc, in a patient treated in a respirator, giving rise to fears, later proved to be ill founded, of a space occupying lesion. The Minneapolis Commission mention one similar case seen by them in recent years Lesions confined strictly to oculomotor nuclei were comparatively rare, and their effects were usually brief.

Disturbances of the 5th nerve are common. When they are complete and bilateral the result can be striking, as in a young lawyer patient of ours whose masseter muscles were totally paralysed One felt tempted to conjecture, in view of the suggested relationship with fatigue, to what extent his profession might have precipitated that localisation !

We saw many more 5th nerve lesions in 1947 than previously or since, about 10% of the earlier cases being affected As is usual, asymmetry was a feature Paresis can be missed very easily unless a systematic examination is made Tests against resistance are indispensable

Facial nerve paralysis is not uncommon, and where it is extreme it is not uncommonly associated with lesions of the lower cranial nerve subgroup and therefore in the more critically ill Although it usually conforms

---

* Notes of a paper read at a meeting of the Fever Hospitals Group of the Society of Medical Officers of Health, May 20 1950

Central Index of Translations

To keep research workers informed of developments in foreign countries the Association of Special Libraries and Information Bureaux is preparing a central index of translations which will include scientific papers, reports, and articles from foreign journals It is intended that the index shall provide a guide to all translations held in this country and the Commonwealth, and all organisations holding translations and willing to take part in the scheme are invited to get in touch with ASLIB A limited number of translations has already been indexed Inquiries and offers of coöperation should be made to ASLIB, 4, Palace Gate, London, W 8

A Teaching Film

Nucleus Film Unit have made a 16 mm silent teaching film on *Taking a Swab* The production was supervised by Prof Robert Cruickshank, and the script was prepared with the help of Professor Cruickshank, Dr R C Mac Keith, and Dr R E O Williams The film was made at St Mary's Hospital It has been found that copies which are lent for hire deteriorate rapidly, and this film is available for sale only from the unit, 21, Soho Square, London, W 1, at £10 per copy Within the British Isles copies can be borrowed for a preview

Chemistry in the Service of Man

In connection with the Festival of Britain the Chemical Council are holding four popular lectures on this subject at the Royal Institution, 21, Albemarle Street, London, W 1 On Wednesday, May 16, at 3 P M , Prof R P Linstead, D SC , F R S , will speak on Chemistry and the Amenities of Life , on May 23, at 3 P M , Sir Jack Drummond, D SC , F R S , on Chemistry and the Food We Eat , on May 30, at 6 P M , Prof J W Cook, D SC , F R S , on Chemistry and the Conquest of Disease , and on June 6, at 6 P M , Sir Cyril Hinshelwood, SC D , F R S , on Chemistry and Modern Thought Admission is free, but by ticket, obtainable from the council, 9, Savile Row, W 1

Mr H J Seddon, director of studies at the Institute of Orthopædics, Royal National Orthopædic Hospital, London, will be giving lectures at the medical schools at Stockholm, Lund, Uppsala, and Oslo during May

An Annotated Bibliography of Cortisone, A C T H , and Related Substances, for the first quarter of 1951, has been compiled by the cortisone committee of the Empire Rheumatism Council Copies (5s each) may be had from the secretary of the council, Tavistock House North, Tavistock Square, London, W C 1

A pamphlet on the *Operation of a Central Syringe Service* has been published by the Ballbrook Surgical Instrument Company Ltd , 9, Blackfriars Street, Salford, 3 Copies may be had without charge

The Chemistry of Inositol is reviewed by Mr Edward R Weidlein, jun , in bulletin no 6 of the bibliographic series issued by the Mellon Institute of Industrial Research Copies may be had without charge on application to the institute, University of Pittsburgh, Pittsburgh 13, Pa , U S A

Diary of the Week

APRIL 29 TO MAY 5

Monday, 30th

ROYAL EYE HOSPITAL, St George's Circus Southwark, S E.1
5 P M Prof Arnold Sorsby Antibiotics
INSTITUTE OF OPHTHALMOLOGY, Judd Street W C 1
5 30 P M Dr H J A Dartnall Physicochemical Aspects of Vision
INSTITUTE OF PSYCHIATRY Maudsley Hospital, Denmark Hill, S.E.5
5 30 P M Dr E Stengel Lecture demonstration

Tuesday, 1st

ROYAL EYE HOSPITAL
5 P M Dr T H Whittington The Phorias—Introduction to Orthoptics
INSTITUTE OF DERMATOLOGY St John's Hospital, Lisle Street, W C.2
5 P M Dr F R Bettley Psoriasiform Eruptions
EDINBURGH POST GRADUATE BOARD FOR MEDICINE
5 P M (University New Buildings Edinburgh) Sir Charles Symonds Intracranial Thrombophlebitis

Wednesday, 2nd

NEWSHOLME LECTURE
5 30 P M (London School of Hygiene, Keppel Street, W C.1) Prof Dugald Baird Reduction of Maternal and Fœtal Mortality (First of three lectures)
INSTITUTE OF OPHTHALMOLOGY
5 30 P M Dr L C Thomson Electrophysiology of the Retina.
MEDICO CHIRURGICAL SOCIETY OF EDINBURGH
8 30 P M (Royal College of Surgeons, 18, Nicolson Street.) Dr D M F Batty Mr W A D Adamson Gastric and Duodenal Hæmorrhage

Thursday, 3rd

ROYAL COLLEGE OF SURGEONS, Lincoln's Inn Fields, W C.2
5 30 P.M Sir Stanford Cade Malignant Disease of the Tongue and Buccal Cavity (Otolaryngology lecture)
ROYAL ARMY MEDICAL COLLEGE, Millbank, S W 1
5 P M Dr W R Bett Episodes from the History of Military Medicine
NEWSHOLME LECTURE
5 30 P M Professor Baird Environment and Child bearing (Second lecture)
ROYAL EYE HOSPITAL
5 P M Dr A M Rackow Interpretation of Skull and Orbital X ray Films
ST GEORGE S HOSPITAL MEDICAL SCHOOL Hyde Park Corner, S.W.1
4 30 P M Sir Paul Mallinson Psychiatry lecture-demonstration
UNIVERSITY COLLEGE, Gower Street W C 1
4 15 P M Prof H A Krebs F R.S Energy Transformations in Living Matter (Second of four lectures)
INSTITUTE OF DERMATOLOGY
5 P M Dr R T Brain Physio and Electro therapy
HONYMAN GILLESPIE LECTURE
5 P M (University New Buildings Teviot Place, Edinburgh) Dr J B King Muscular Tone of the Gastro intestinal Tract
UNIVERSITY OF ST ANDREWS
5 P M (Medical School Small's Wynd, Dundee) Prof. J McMichael Pharmacology of Heart failure in Man.

Friday, 4th

ROYAL COLLEGE OF SURGEONS
5 P M Dr Howard Gray (Mayo Clinic) Clinical and Experimental Investigation of the Circulation of the Liver (Moynihan lecture)
NEWSHOLME LECTURE
5 30 P M Professor Baird The Rôle and Organisation of a Maternity Service (Last lecture)
MIDDLESEX HOSPITAL MEDICAL SCHOOL W 1
4 P.M Sir Edward Mellanby F R S Chemical Manipulation of Food (Sanderson Wells lecture)
ROYAL EYE HOSPITAL
4 30 P M Mr A J Cameron Theatre Preparation and Post operative Procedure
INSTITUTE OF OPHTHALMOLOGY
5 30 P M Mr F Ridley Contact Lenses

Saturday, 5th

BIOCHEMICAL SOCIETY
11 A M (Department of Biochemistry South Parks Road, Oxford) Scientific papers

CORRIGENDA *Calcium Metabolism in Hyperthyroidism*—In figs 1–4 of the paper by Dr J Green and Dr A Lyall (April 14, p 828) the values of nitrogen, phosphorus, and calcium charted are grammes *per day* and not g per 100 ml as shown Having inadvertently introduced this error, we much regret any confusion caused

Activity of Plasma Labile Factor in Disease—In Dr Mario Stefanini s article of March 17, the penultimate sentence of the left-hand column on p 607 contains the words : " 0·1 ml of each dilution is added to 0·09 ml of stored plasma " This should read " *0·01* ml of each dilution," &c.

the systolic pressure may be normal. Hyperpyrexia is common, but the skin is cold and clammy terminally, with a mottled cyanosis. The patient is usually alert but restless and confused.

ENCEPHALITIC GROUP

Symptoms of encephalitis are exceedingly common in poliomyelitis. What is not so certain, however, is their cause. They generally appear as apprehension, restlessness, irritability, twitching of facial muscles, and tremors. Insomnia is well marked, and this, in young patients and in the absence of pain, is remarkable. In other cases, and less often, there may be confusion, somnolence, and even coma. I observed one such case in 1947 (Kelleher et al. 1949) in which aphasia, tremors, severe nystagmus, and a form of generalised tonic decerebrate-like rigidity were noted, preceding final coma and death. Despite absence of signs of lower-motor-neurone lesions there was histological evidence of gross destruction of anterior-horn cells at all levels in the cord. There were foci of acute inflammation and degeneration of parenchyma, in places almost purulent, in the basal ganglia, mid-brain, pons, and medulla—most severe in the mid brain. The cerebral cortex showed only œdema and congestion.

There is strong belief, however, particularly expressed in the American reports, that the very commonly noted encephalitic signs in poliomyelitis are in many cases not necessarily evidence of damage by virus but are due to hypoxia, for it has been claimed that oxygenation often caused the signs of encephalitis to disappear.

Bulbar poliomyelitis seems to be intimately concerned with the reaction of nervous tissue, to hypoxia or repeated anoxia. Thorner and Lewy (1940) held that single periods of anoxia lasting sixty seconds might produce distinct morphological change in brain tissue. Since then it has been shown that brain cells may become necrosed after a few minutes' anoxia, and that repeated anoxia can produce widespread damage to the brain.

Apart from the general effects on brain cells, the more critical results of hypoxia on important areas, such as the respiratory and vasomotor centres, cannot be ignored.

If, as some believe, the permeability of the capillary vessels of the lung alveolar walls is affected, the production of lung œdema may be facilitated. Workers in recent years describe further studies on the long terms effects on patients who had been subjected to periods of anoxia, and some cite 100% permanent damage, with resulting changes in personality and behaviour. Very many reports indicate the effects of anoxia due to cardiac arrest on the operating table.

Galloway (1947) states that the symptoms of hypoxia may be difficult to interpret where a severe infection may coexist, but cites restlessness, disorientation, and uncoöperativeness as early symptoms. He also warns that a shock like pallor, rather than cyanosis, may be a feature in terminal stages. This seems to me to smack of the white asphyxia of the late stage of obstruction in laryngeal diphtheria, believed to indicate imminent cardiovascular failure. Though the ill effects of hypoxia on cardiovascular and respiratory centres and on medullary cortex may be accepted as occurring, I find it difficult to understand how the severe oxygen defect seen so often in laryngeal diphtheria does not cause more lasting damage. I cannot recollect any patient, however ill, who, having survived the first period of shock following laryngeal diphtheria and tracheotomy, or its later pulmonary complications, did not appear to make an apparently complete recovery without evidence of postanoxic cerebral damage.

The symptoms of hypoxia include restlessness, dyspnœa, sleeplessness, and anxiety in the earlier stages, progressing through increasing pulse rate and blood pressure, cyanosis, and increasing dyspnœa to the final stage, where gradually increasing cyanosis merges into grey pallor and diminishing consciousness. Facial muscle twitching may also be noted.

The causes of anoxia in bulbar poliomyelitis (quite apart from that resulting from lesions of the cervical cord producing paralysis of respiratory muscles, and from interference with the proper functioning of vital autonomic centres in the medulla) are entirely mechanical or local. The most important defect of all is the accumulation of secretions in the pharynx mainly from involvement of the 10th cranial nerve. Also important is laryngeal abductor paresis or paralysis. Reflex laryngeal spasm, through irritation by food or fluid particles where glottic protection is defective, may be more important than is generally appreciated. The not uncommon complication of pneumonia and, particularly, atelectasis, will add to, or produce, hypoxia. Finally there is the dreaded complication, pulmonary œdema.

The importance of recognising the serious effects of lesions of the respiratory and cardiovascular centres in bulbar poliomyelitis is undoubted, for in a small proportion of cases it may be possible to save the patient. Recognition of the more local and mechanical defects, leading to defective oxygenation in bulbar poliomyelitis is, because of the claimed results for therapy, of much greater importance.

TREATMENT

Drugs

No drug has so far been produced that will specifically attack the virus, although there is experimental evidence of the susceptibility of the virus to certain chemicals, notably benzidine dyes and nucleic acid derivatives.

Antiserum need only be mentioned to be dismissed, owing to its failure over the years. The antibody content of serum, though undeniable, is variable, and the antibody may be effective only against one specific strain.

None of the antibiotics has yet proved useful against the very small poliomyelitis virus, and any claims of their value must be examined with great caution.

Claims have been made for the efficacy of huge doses of ascorbic acid, given parenterally and orally. Klenner (1949) in particular claimed outstanding results in the prevention of paralysis by this vitamin, but apparently did not use controls.

Curare has been advocated for bulbar poliomyelitis, notably and originally by Ransohoff (1947). The rationale of this therapy is the relaxation of muscular spasm, whether of bulbar or spinal origin. Applied to the respiratory muscle defects and in the presence of effective antidote its use seems rational. In pharyngeal dysfunction, where the major factor is spasm, it also seems sensible. Advocates for the use of curare claim that tracheotomy may be necessary, even in the most severe cases, only when there is bilateral complete abductor paralysis of the vocal cords. It is also said to obviate the use of the respirator. Others argue that the curarised patient is in even greater danger of obstruction from the collapsed throat and that he needs even more help from the respirator.

Sedative drugs have their uses in the pure encephalitic types, but their use in cases with respiratory depression and in cases with lesions of the lower cranial nerves and accumulation of buccal secretions may be dangerous.

Other Treatment

Bower (1949) recommends hot compresses to alleviate the tight respiratory muscles (the "frozen" chest). We have tried hot compresses, but usually only in respirator assisted cases, and I cannot express any strong views on their value.

Both Bower and others have urged the necessity for maintaining the electrolyte and fluid balance, but they emphasise the danger of overhydration, particularly to a lesion of a lower motor neurone, on rare occasions it may be more diffuse

Involvement of the 8th nerve, giving rise to vertigo and vomiting, is often seen in poliomyelitis Deafness seems to be so rare as to be extraordinary

Lower Subgroup

When we talk of the dangers of bulbar poliomyelitis it is usually the lesions of the 9th, 10th, 11th, and 12th cranial nerves, particularly the 10th, that give rise to anxiety Although from time to time we may suspect complications arising from destructive lesions of vital autonomic centres, causing disturbances in respiratory and cardiovascular function, it is the effects of respiratory difficulty, initiated by damage to not only the nucleus of the 10th cranial nerve but also the nuclei of the 11th and 12th cranial nerves that many of us have had cause to fear, and with every reason

It is with the accumulation of secretions owing to nervous dysfunction of the pharyngo laryngeal area that we must be principally concerned Innervation of this area is through the 9th, 10th, 11th, and 12th cranial nerves, particularly the 10th

Brahdy and Lenarsky (1934) described four types of dysphagia occurring in poliomyelitis regurgitation through the nose, accumulation of food, fluid, or oro pharyngeal secretions in the pharynx, regurgitation of food from the œsophagus, and inability to shut off the larynx, leading to cough and distress

Although in most cases of pharyngeal paresis or paralysis the soft palate is more or less involved, it is when that organ is affected alone, leading to projection of food into the nose, that we should have least cause to worry A pharynx functioning sufficiently well to accentuate a palatal defect is one which should be able, with care, to handle secretions and food

Great danger arises when deglutition troubles become extreme owing to the tendency for accumulations in the pharynx to interfere with the airway, and we must be constantly on the watch for signs of defects Though a nasal voice alone is not necessarily of serious import, it should constantly alert one to the possibility of more extensive involvement The pharynx must be carefully and repeatedly examined for puddling of secretions No difficulty in determining the degree of danger will arise when large and obvious secretions are present, but not infrequently, in my experience, quite small accumulations, not easily seen on the postpharyngeal wall, or accumulating in the glottic area, may cause considerable distress, if not immediate danger The danger in the lesser collections can arise from aspiration of even very small quantities into the larynx, which may set up reflex spasm and dangerous collapse I have known of one such case where an adult patient, injudiciously given a teaspoonful of water, collapsed and died In addition these small collections are not easily dealt with by suction apparatus With the patient lying supine in a respirator they can be still more troublesome, and they can be extraordinarily exhausting to the patient The accumulations may be very extensive, because up to 1500 ml. of oropharyngeal secretions has to be dealt with in twenty four hours The threat to the patient's airway is constant or recurrent

Apart from reflex spasm of the glottis and the hazards of defect in glottic control, 10th nerve damage may be responsible for abductor paralysis of the vocal cords, leading to rapid asphyxia Fortunately, this has not happened here, although we have had moments of anxiety where partial abductor paralysis was causing distress

LESIONS OF RESPIRATORY CENTRE

Grave dangers are associated with lesions of the autonomic centre in the ventral reticular substance of the medulla oblongata Such lesions have often been demonstrated histologically Clinically demonstrable lesions seem to be comparatively rare, but I doubt whether the condition is really so infrequent, for in the absence of special experience diagnosis must be difficult The difficulties are increased where the lesion arises in a case already complicated by palsies of lower cranial nerves, with or without respiratory dysfunction of spinal origin

Symptoms resulting from this lesion are believed to develop more often some days after the appearance of signs of lesions of cranial nerves, which may be mild. The patient usually exhibits irregularities of depth and rhythm of respiration Breathing tends to be shallow, although occasionally deep amplitude gives that reassurance about the innervation of the diaphragm and intercostals which one may be anxiously seeking Periods of apnœa may occur before final collapse The patient may be apprehensive and restless Some of the symptoms have been ascribed to hypoxia A raised blood pressure has been found in some of these cases, and has been attributed to overaction of the pressor centre in the reticular substance of the medulla, where it lies close to the respiratory centre, particularly if the vasodepressor area has been damaged. At the same time it is agreed that anoxia and hypercapnia may also cause hypertension

The respiratory centre seemed to be depressed in the following illustrative cases

Case 1 —A boy, aged 14, was admitted to the Western Hospital on March 14, 1949, with bilateral asymmetrical palatal paresis He complained of difficulty in swallowing, but no accumulation of secretions could be seen. There had been regurgitation of fluids into the nose two days before admission Slight stridor noted at times, especially on deep inspiration, was due to laryngeal abductor paresis The diaphragm was partly defective, but intercostal action was good The occasional presence of mucus in the throat prompted caution in the use of a cabinet respirator When the patient was tried in the respirator there was failure of synchronisation and there seemed to be a greater tendency to inspiratory stridor The respirator was therefore discontinued

For six days he was treated by postural drainage for the somewhat increased pharyngeal weakness, although it was suspected that much of the trouble was due to defect in glottic control Respiratory power remained adequate On the sixth day after admission he complained that he could not breathe properly Although his airway was clear, and there was adequate respiratory amplitude and entry of air, the respirations had slowed to about 10 a minute, with brief periods of apnœa The depth of respiratory excursion also varied, being at times adequate, at others shallow The boy was fully conscious, with good colour, but extremely apprehensive He asked to be placed in the respirator, a step which had already been decided, and, to our relief, there was good synchronisation. After a stormy passage he made a full recovery It is possible that anoxic damage to the centre, and not necessarily virus attack, may have precipitated the disturbance

Case 2 —A boy, aged 6 years, had palsies of the 7th and 10th cranial nerves, with mucus in the pharynx, but a clear airway was maintained by postural drainage There were no spinal pareses and no paresis of respiratory muscles The depth and rhythm of respiration varied within wide limits—at times periods of apnœa, at others shallow breathing followed a series of very deep inspirations There was no cyanosis The pulse was rapid The boy was quiet but showed occasional apprehensiveness He died suddenly thirty six hours after admission, after vomiting dark bloodstained fluid For two hours before death his respirations were, with full amplitude, of Cheyne Stokes type

LESIONS OF CIRCULATORY CENTRE

This complication has not been seen in our cases It occurs occasionally in the absence of lesions of cranial nerves but more often with such lesions The mortality is 80–90%, despite treatment The principal clinical features are a florid dusky red colour, cherry red lips, and a very rapid pulse The blood pressure varies but is usually low, with a very low pulse pressure, although complications were kept at a minimum and the operation carried a risk of less than 1%.

These and other writers emphasise that the operations should be high—i.e., through the second and third tracheal rings—and that constant care will still be necessary to keep the trachea aspirated, and it may also be advisable to administer oxygen, humidified and under pressure, to prevent anoxia and lung oedema. Postural drainage must be maintained also. Prophylactic penicillin should be administered. A 3% solution of warmed sodium bicarbonate, followed by isotonic sodium chloride solution, is administered through the tube by a dropper and afterwards carefully aspirated through a bevelled rubber tube with the patient in the postural drainage position.

The high tracheotomy is planned in anticipation of the event, which is not rare, that the patient must later be nursed in a respirator. A device for holding down the rubber collar towards the sternal notch can readily be devised and should be kept ready for use.

The same workers also discuss tracheotomy in a patient already in a respirator and point out the awkwardness of the technique in this emergency. The respirator is open, and the patient is oxygenated through the endotracheal tube, through which oxygen can be administered under pressure.

Collarless respirators have obvious advantages in this contingency. The Swedish Stille comes to mind, and for both immediate and post-operative care should be far preferable to the tank type of machine.

Peterson and Ward (1948), discussing the problems of technique and aftercare for tracheotomy cases in respirators, draw attention to the new type of Monaghan collarless (cuirasse type) respirator, for which they claim great advantages both before and during operation and in aftercare.

I mention here two cases met with last year.

Case 3.—A woman, aged 44, was admitted with bulbar poliomyelitis; she had facial and pharyngeal paralysis but no spinal defect. There was full respiratory power and no obvious lesion of the autonomic respiratory centre. Despite an adequate angle of postural drainage, pharyngeal secretions were accumulating, cyanosis rapidly developed, and all efforts at assistance seemed to be useless. We felt that a tracheotomy might help, and I called in a laryngologist for the orderly planned operation which is advocated. Finding the airway apparently clear, he thought tracheotomy inadvisable—at any rate until after a further examination next day. Unhappily, the patient died an hour later. At necropsy the trachea and bronchi were found filled with frothy mucus. There was much oedema of all lobes of the lungs.

Case 4.—A boy, aged 8 years, had pure bulbar poliomyelitis showing as complete pharyngeal paralysis. No degree of postural drainage or aspiration appeared to help. There was full respiratory power. Again we called in a laryngologist, who could find no sufficient reason for tracheotomy. With the boy almost in extremis, an anæsthetist put in an endotracheal tube. There was a dramatic improvement; tracheal râles disappeared, and the patient was quiet and now obviously well oxygenated. A few hours later he collapsed and died suddenly. The tracheal tube was removed and was followed by a large accumulation of mucus which was obviously blocking the distal end. At necropsy the trachea and main bronchi were found plugged with dense mucus. There was congestion and emphysema of the right lung and a wedge-shaped patch of collapse at the base of the left lung. The surface of both lungs showed petechiæ.

We are probably all aware of the dire results of the combination of bulbar (lower cranial nerve) and spinal (cervical cord) lesions, and in the absence of specific techniques a 100% mortality is not rare. The American workers claim that a clear airway, which is essential for patients when treated in respirators, can be achieved only by tracheotomy at an early stage, preferably before the patient is placed in the machine. Oxygen under pressure is advised if there is any suspicion of pulmonary oedema. Other measures adopted, or advised, are bronchoscopy, suction through the tracheotomy opening and [illegible] periodically. It is recommended that humidified oxygen under pressure is being used [illegible] [illegible] positive pressure within the cuirass. Prior to these measures the Minnesota workers had a 75% mortality for the mixed spinal and bulbar group.

These workers recognised about 20% of bulbar patients with involvement of the respiratory centre; but these were dealing with a particularly severe virus. In them also they emphasise the necessity for oxygen [illegible] 100%, particularly because atelectasis and [illegible] congestion are likely to develop. They state that clinical detection of these complications is shown by frequent chest examination [illegible] (Minnesota Poliomyelitis Research Commission 1947).

A mortality of up to 100% was experienced when the respirator was used, and they explain that forced respiration in the presence of any obstruction in the airway will produce pulmonary oedema. They think tracheotomy essential in such a contingency.

They also advise, for lesions of the respiratory centre, oxygen and, in the presence of obstruction, tracheotomy, but point out that the results are in any case extremely poor.

Use of Respirator in Bulbar Poliomyelitis

It seems to be generally agreed that the use of the respirator in bulbar poliomyelitis is contra-indicated unless a clear airway is ensured—by postural drainage, aspiration, or particularly tracheotomy, or by a combination of these measures.

CONCLUSIONS

From our experience at the Western Hospital and from a study of the American literature I hold that we should seriously consider tracheotomy and other appropriate remedial measures for the not inconsiderable number of cases of poliomyelitis in which dangerous bulbar lesions interfere with free oxygenation.

The poliomyelitis team should include an anæsthetist and a laryngologist, who should be prepared to perform tracheotomy as a deliberately planned measure of prevention rather than cure of the dangerous sequelæ of respiratory obstruction.

approximately 140,000 persons suffering from active tuberculosis are at large among the population of England and Wales and ... this figure is rising. All of these persons are potential sources of danger and a menace to non-infected individuals, particularly infants and adolescents. ... To me the great danger that we are facing in tuberculosis is the creation of a non-infected younger generation amidst an infectious older one. We should be warned by the rise in the incidence of the disease in the older age groups, particularly in males, and the simultaneous increase in notification of primary infection in young adults, particularly females. I would not venture to suggest that the tuberculosis problem reduces itself to the control of old men and young maidens, but I do suggest that we should be sure that every means is used to build up the resistance of susceptible age groups, so that they will not develop active disease from their first infection with virulent tubercle bacilli.—Prof. F. R. G. HEAF, *Brit. J. Tuberc.* 1951, 45, 41.

the danger of cerebral œdema from excess of sodium Excess fluid may also precipitate œdema of the lungs Repeated intravenous injections of glucose are advocated with a view to cerebral decongestion

Whether or not to institute nasal feeding has always been debatable In the milder cases of pharyngeal dysfunction, particularly where there is no glottic leak, nasal feeds may be very useful, or even necessary, where dehydration may otherwise be expected The feed must in every case be given with the greatest caution and only by those whose technique is known to be above suspicion In the presence of inadequacy of glottic closure, or fear by the patient, and particularly when vomiting or nausea might be caused, nasal feeds are a very real danger I have seen many cases where sudden collapse has followed during or shortly after the feed that I fear them except in the most suitable type of case In postdiphtheritic paralysis nasal feeds are extremely useful and only rarely dangerous In bulbar poliomyelitis it is another matter, especially if the patient is being treated in a respirator Regurgitation of the feed from the œsophagus may be a factor in many of the cases where a sudden vomit is supposed to be the cause of collapse Such a possibility is, of course, accepted in the dysfunction due to a lesion of the 10th nerve

The prominence recently given to anoxia and its dangers has drawn attention to its correction The administration of oxygen has to be considered It is a rational procedure, particularly where it can be given without disturbing the patient Tents are often advocated, and we have found them of value in selected cases, but it must be borne in mind that extra oxygen is unlikely to help where the airway is obstructed or is not frequently cleared

We now reach the crux of the whole problem in the physical correction of the results of pharyngeal defects in bulbar poliomyelitis How is the airway to be kept clear? There is hardly a medical problem today which is more debatable, at least as regards some aspects of its suggested correction However, certain remedial approaches are acceptable and necessary The first of these is postural drainage, by which fluid secretions must be kept away from the lower pharynx

Apart from the danger of asphyxia, or aspiration pneumonia and/or atelectasis, there is also a firmly held theory that œdema of the lungs may be precipitated by obstruction The mechanics of this complication are explained by the high negative intratracheal and intrabronchiolar pressure caused by obstruction in the face of strong inspiratory efforts As a result there is a cuffing effect on the pulmonary capillaries, with consequent transudation of fluid, plasma, and even red cells into the alveoli It is suggested, as a corrective, that 60% oxygen be given, preferably with a positive mask pressure of 2–6 cm of water (Minnesota Poliomyelitis Research Commission 1947) Obviously, prevention is better than cure of this complication, but unfortunately too many patients are admitted at a late stage with obstruction already established The frothy bloodstained fluid from the alveoli will then be added to the buccal secretions to be dealt with, and a vicious circle is established

Early postural drainage, assisted by aspiration, should be the aim Aspiration may be intermittent, from the pharynx, or continuous via a nasal catheter A warning must be uttered against indiscriminate interference with, or roughness in handling, the introduced suction cannula

Cardon (1950) believes in intermittent laryngeal aspiration through a urethral catheter passed through the nose and guided into the larynx during inspiration, when the vocal cords are separated

For postural drainage of the pharyngo laryngeal area to be effective in the supine position there should be a tilt of at least 20°, and preferably more, from the horizontal In the prone position it may be less. A lateral position may help by directing the accumulated secretions to an area inside the cheek where they are more readily accessible It is obvious from a study of the angle of the terminal bronchioles at the bases that an angle of tilt of 45° or more may be necessary in the supine patient to clear these tubes where secretions have caused atelectasis With the patient prone this angle may be much reduced

I must confess to being puzzled about the different clinical behaviour of the pharyngeal paralysis cases seen in poliomyelitis and that in postdiphtheritic paralysis In diphtheria, so long as the heart held out and respiratory paralyses did not supervene, I have been confident that, provided efficient postural drainage was maintained, the patient's recovery was reasonably certain The question of anoxia, hypoxia, and pulmonary œdema did not seem to arise, certainly it was never thought that tracheotomy might be necessary to clear the airway Even in the absence of defect of the respiratory muscles the poliomyelitis pharynx presents a very different picture to me Perhaps it lies in the mechanism of lung œdema, possibly activated by disturbances of the vasomotor pressor centre in the medulla, causing high blood pressure and associated with right-sided dilatation of the heart Hypopiesia is the invariable accompaniment of toxic diphtheria

Tracheotomy in Bulbar Poliomyelitis

This is a thorny subject, and I cannot speak from experience, for so far tracheotomy has not been done in bulbar poliomyelitis in this hospital Although there are strong and vociferous advocates for this measure in the U S.A, there are also the rebels there, who, though grudgingly admitting its use in certain selected cases, are cautious in expressing favour towards it

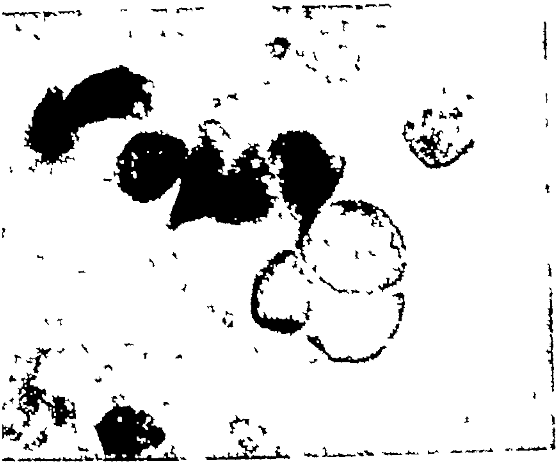
The advocates of tracheotomy press for its adoption at even a very early stage in bulbar poliomyelitis—i e, before hypoxia is present and certainly long before lung œdema is manifest Their views must be respected, for their experience is undoubtedly vast A claim for the recovery of at least 25% of patients who would otherwise have been lost is confidently made by them

Bower (1949) speaks of an experience of 233 tracheotomies in 284 bulbar cases since 1946, and claims increasingly good results where prevention rather than correction of anoxia was adopted

Galloway and Seifert (1949) are among the most enthusiastic advocates of tracheotomy They cite the following indications for operation

(1) Progressive anoxia, with secretions in the upper airway
(2) Unconsciousness or pronounced restlessness in a patient who does not respond to other treatment in a few minutes
(3) Pronounced restlessness or stupor in a patient in a respirator, even if the paralysis is apparently of a spinal type
(4) Accumulation of fluid, not otherwise certainly taken care of, in a patient who requires a respirator
(5) Bilateral spasm or paralysis of vocal cords
(6) Rapidly progressive bulbar symptoms
(7) Grave signs of vasomotor failure
(8) Untrained or inefficient attendants, inadequate equipment, or poor coöperation of the patient, with doubt that the airway will be constantly kept free from secretions

These workers emphasise that tracheotomy should be carefully planned and deliberate, rather than a rushed emergency, and that it should be performed preferably over a bronchoscope or endotracheal tube, the airway being kept clear thereby and pressures equalised It also kept the airway clear postoperatively In this way



(case 2)—Bone-marrow Group of large rounded cells largest in diameter and one of irregular shape with double nucleus

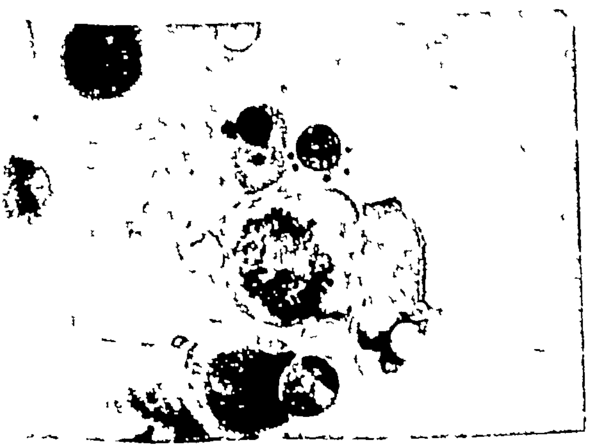
lood-count showed severe anæmia red cells 2,660 000 mm , Hb 6 2 g per 100 ml , white cells 6400 per c mm rential count normal)

ne marrow biopsy showed that nearly all the cells were primitive cells, with large fairly patterned nuclei and y dark blue or light-blue cytoplasm, often vacuolated 2) the cells were arranged in groups for the most part, a few were very large, with irregularly shaped nuclei r cells were few

ogress —The condition progressed only slowly at first weeks later a biopsy of the skull tumour showed a picture was thought to be neuroblastoma or reticulosarcoma iography at this time showed widespread lesions in the bones and the skull The case was regarded as unsuitable X ray therapy Blood transfusions were given, but the ent became steadily more anæmic Four days before th some of the primitive reticulum cells appeared in the od No necropsy was permitted

ase 3 —A man, aged 41, was admitted to a medical ward ause he had had a severe epistaxis and was seriously emic. Increasing pallor had been present for four months, l for the past six weeks he had had an undiagnosed pyrexial ess

n admission his temperature was 100 2°F He was pale but icteric There were no skin lesions There was no enlarge nt of the liver spleen or lymph glands The urine was rmal, and no abnormal signs were found elsewhere The cells were reduced to 1,340,000 per c mm and Hb to g per 100 ml , white cells were 3500 per c mm (differential int normal) , platelets were reduced to 10 000 per c mm



ig 3 (case 3)—Bone-marrow Very large abnormal reticulum cell, 23 μ in diameter in mitosis ; below it a smaller cell of the same type above to the left a normal reticulum cell and to the right a normoblast.

The nose was plugged and blood transfusion given, but improvement was only temporary

The *sternal bone marrow* was very unusual (fig 3), it contained many very large cells, the smallest being about 15 μ in diameter, these cells had large rounded or oval nuclei filling most of the cell and having a finely stippled chromatin pattern the cytoplasm varied from moderately dark to deep blue and was vacuolated Many of these large cells were multinucleated, and some exceptionally large forms resembled a syncytium Mitotic figures were relatively common Reticulum and plasma cells of normal aspect were common Erythroblasts were relatively few and normoblastic in type, some of them showed nuclear abnormalities as well

Progress —No treatment had any effect, the hæmorrhages continued, and the anæmia worsened On the day before death a few cells like myeloblasts appeared in the peripheral blood The patient died eleven days after admission

Post mortem Findings —Histological sections from necropsy material showed extensive infiltration of lymph glands and spleen with cells similar to those seen in the bone marrow, numerous giant cells were present In the liver there was a diffuse infiltration with little destruction of liver cells, giant cells were present here also

Case 4 —A doctor, aged 45, had had pain in the chest, especially near the lower scapular region, for six months Radiography had shown no abnormality About two weeks before he was first seen he had noticed blurring of vision that soon progressed to diplopia He was examined by a neuro surgeon, who found a complete left sixth nerve palsy There was flattening above both scapular spines and tenderness over the right supraspinatus muscle, there was pain and tenderness in the fifth and sixth right intercostal spaces No obvious cause for this condition was found, and the patient was admitted to hospital fifteen days later In that time his general condition had deteriorated gravely

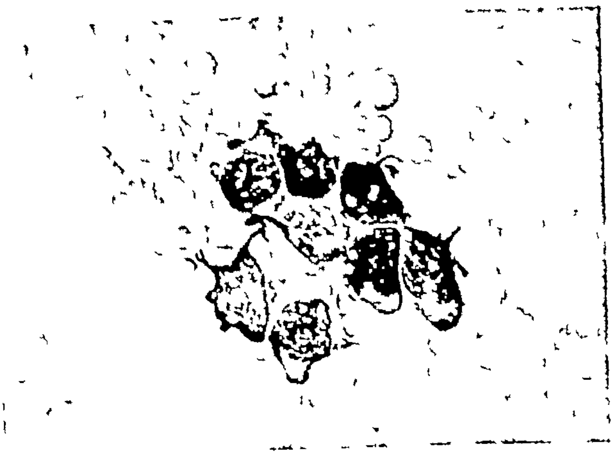


Fig 4 (case 4)—Bone-marrow Group of abnormal reticulum cells, some rounded and some irregular showing relatively coarse chromatin pattern of nucleus and very scanty cytoplasm ; largest cell in the group is 17 μ in diameter

On admission the right infraspinatus muscle was now grossly wasted and the left showed early wasting The sixth nerve palsy was unchanged The head and neck movements were stiff there were no other abnormal signs Radiography of the chest showed notably enlarged mediastinal lymph-glands and the appearance of three dorsal vertebræ suggested metastatic destruction of bone

A *blood count* showed red cells 4,870,000 per c mm , Hb 13 6 g per 100 ml , white cells 6900 per c mm (70% polymorphs and 1% classed as "abnormal reticulum cells")

Sternal marrow was packed with masses of large irregularly shaped cells with large nuclei occupying most of the cell and scanty dark blue cytoplasm that was sometimes vacuolated These cells were sometimes enormous, they occurred mostly in groups, and some of the groups looked more like syncytial masses than separate cells (fig 4) Mitotic figures were quite common Few normal granulocytes and erythroblasts remained The whole clinical and pathological picture suggested a rapidly extending reticulosarcoma

MYELOID RETICULOSIS
ITS DIAGNOSIS AND COURSE

M C G Israëls
M Sc , M D Manc , F R C P
LECTURER IN HÆMATOLOGY IN THE UNIVERSITY OF MANCHESTER

It has become common practice to classify as " acute reticuloses " those syndromes which run a relatively short course, have features resembling the leukæmias and Hodgkin's disease, but have neither the blood picture of the former nor the typical histological changes of the latter Other terms have been " reticulo endotheliosis," or " aleukæmic stem cell leukæmia," and it is quite likely that some of the cases in the Continental literature described as " paramyeloblastic leukæmia " were of this type In this confused field retrospective diagnosis is particularly unrewarding, and those interested in the historical arguments about these conditions will find them adequately set out by Downey (1938) It is not unfair to say that the diagnosis has most often been made after histological examination of post mortem material For instance, the acute histiocytic medullary reticulosis described by Bodley Scott and Robb Smith (1939) presented a recognisable clinical syndrome of pyrexia, splenomegaly, moderate enlargement of lymph glands and sometimes liver, anæmia, and leucopenia The bone marrow was not examined during life, but foci of histiocytic cells were reported in the sections of bone marrow obtained at necropsy, and the diagnosis was made by histological examination of tissues from the post mortem examination In Hodgkin's disease the bone marrow commonly shows a normal hyperplasia and it is extremely unusual to find Reed Sternberg cells either by the usual smear technique or by aspirating fragments and preparing sections (Limarzi and Paul 1949)

The cases described here were all diagnosed during life by the peculiar cells found in the bone marrow, and involvement of the bone marrow was the constant clinical finding The clinical picture varied but was fairly characteristic Very few such cases have been published Evans et al. (1949) described one in a girl, aged $14^1/_2$, who developed firm tumour like nodules over the left scapula and in both breasts , she had anæmia but, at first, no hæmorrhagic symptoms In the bone marrow smears many odd looking very large cells with nuclei up to 50 μ in diameter were found , the cells had a light blue cytoplasm, the nuclei were delicately reticulated and vesiculated , only a few were seen in mitosis Sections from a biopsy of one of the nodes were reported as " reticulosarcoma " The patient was given X ray treatment, but it was ineffective , the anæmia increased, a hæmorrhagic syndrome with a low blood platelet count developed, and she died in a few weeks Necropsy showed infiltration of all lymph nodes and spleen , the pancreas was almost replaced by tumour tissue , only minute groups of cells were seen, however, in the liver and kidneys The final diagnosis was " possibly stem cell lymphosarcoma " Custer (1949) reproduces pictures from bone marrow biopsy smears and post mortem sections from a patient who presented with anæmia, leucopenia, and thrombocytopenia The marrow smear shows large cells with bizarre multiform nuclei, blue grey cytoplasm, and well defined borders , some cells appeared to form a syncytium , the marrow sections showed that the normal tissue was displaced by these polymorphic giant cells, and similar cells were found in the lymph nodes, liver, and spleen Orchard (1950) reports a case of Letterer Siwe's syndrome, in a child of $3^1/_2$ years, in which abnormal cells that he calls " hæmohistiocytes " were found in the peripheral blood and the bone marrow biopsy smears

CASE RECORDS

Case 1 —A housewife, aged 51, was admitted to hospital with five weeks' history of chill, general malaise, aching pains, and loss of weight No hæmorrhages had occurred

On admission she looked ill and had pyrexia up to 102°F There were numerous soft palpable lymph glands, not much enlarged, at the base of the neck and in the axillæ The spleen was palpable and soft, the liver was not enlarged The cardio vascular, respiratory, and central nervous systems presented no exceptional features , the urine was normal

A *blood count* showed no anæmia red cells 4,660,000 per c mm , Hb 13 6 g per 100 ml , white cells 14,100 per c.mm. (polymorphs 53 5%, lymphocytes 27%, monocytes 1 5%, plasma cells 0 5%, and 27% were large cells of irregular, often elongated, shape, with large irregular nuclei occupying most of the cell)

A *sternal marrow smear* showed large numbers of these unusual cells , they varied in shape from an irregularly circular to an irregularly elongated outline , the cytoplasm was pale or moderately deep blue, and sometimes a few azure granules were seen , a typical cell is seen in fig 1 Some of the cells had a vacuolated cytoplasm, and some appeared to have phagocyted fat globules Mitoses were seen but were few Granulocytes appeared normal and there was an average number of normal erythroblasts present

Post mortem Findings —The patient's condition deteriorated rapidly, and she died seven days after admission At necropsy the abdominal lymph glands were notably enlarged and soft , the spleen weighed 1100 g and the liver 2050 g , the cut surface of the liver was mottled with small grey and hæmorrhagic areas Histological sections showed that the liver tissue was widely infiltrated with large round cells and large irregular cells resembling those seen in the marrow , in many areas the liver cells were entirely replaced by masses of these cells The spleen, lymph glands, and femoral bone marrow also showed extensive infiltration, like that seen in leukæmia

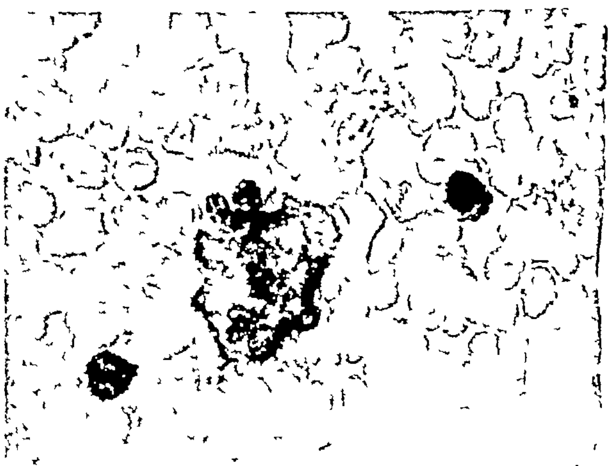

Fig 1 (case 1)—Bone-marrow smear Very large abnormal reticulum cell 30 μ × 22 μ with dark-staining irregular nucleus and dark vacuolated cytoplasm , polymorph next to it.
The smears shown in this and subsequent figures were all stained with Jenner-Giemsa and are reproduced at the same magnification (× 750)

Case 2 —A girl, aged 3 years 3 months, was admitted to hospital with the history that, six weeks before, she had fallen downstairs and bruised her eyes Three weeks later she had complained of headache, and proptosis was noted , her skull had been radiographed, but no fracture was found.

On admission both eyes were severely proptosed, the left more than the right, and there were subcutaneous hæmorrhages in the eyelids Firm tumours, about 2 cm across were present at the outer edge of the right supraorbital ridge and below the inner end of the left ridge The skull appeared widened between the parietal eminences , radiography showed widening of the sutures, and radiating spicules of bone in the supraorbital areas Lymph glands were slightly enlarged in the neck, but not elsewhere In the abdomen the liver was palpable 4 cm below the costal margin , the spleen was not palpable There was no rash and no hæmorrhage except in the eyelids odd cells were characteristically gathered into small s. Mitotic figures were seen in some of the large cells al granulocytes and erythroblasts were present but r

atment and Progress—Blood transfusion and nitrogen rd were given, but the effects were disappointing he patient died four weeks after admission

t mortem Findings—The liver and spleen were enormous, larged lymph glands were found The microscopical es were most striking in the liver, which was grossly ited with large round cells and multinucleated giant imilar to those in the marrow smears, in the spleen the ghian bodies were no longer visible and the pulp was ellular, though giant cells were less prominent than in er

DISCUSSION

e clinical histories of these patients show a remark variety of syndromes, these syndromes resemble in those that have been recorded in leukæmias, but has always been some unusual feature that caused ition about the diagnosis The cases vary from to relatively chronic

e 1 presented as an acute leukæmia, but, although there ardly any anæmia, the patient was gravely ill and died six weeks after the onset, the necropsy showed wide l infiltration of abnormal cells like that seen in acute mia

e 2, when first seen, might have fitted the diagnosis of ma, anæmia was present from the beginning, but no mal cells were seen in the peripheral blood until just death, the course was about two months

e 3 presented the clinical picture usually associated with aplastic anæmia rather than acute leukæmia, there severe hæmorrhage and pyrexia, but no enlargement of spleen, or lymph glands, and, again, abnormal cells red in the blood only just before death, the course was eight weeks

case 4 the neurological signs drew attention to involve of the dorsal vertebræ and mediastinal glands, there was table anæmia, and there were few abnormal cells in the , the course was a little longer, being about three hs.

e 5 presented with thrombycytopenic purpura and gross omegaly, and the blood picture reflected only the loss of , the purpura was oddly distributed, being almost letely limited to the upper half of the body, again no rmal cells appeared in the peripheral blood until the last progress of the disease was much less rapid in this case, otal course being about six months

e 6 was almost chronic, the disease lasting some nine hs, and the presentation was that of a chronic leukæmia anæmia, and gross hepatomegaly and splenomegaly, iagnosis from chronic myeloid leukæmia was only made the bone marrow was examined.

e sole unifying feature in all these cases has been infiltration of the bone marrow with the grossly rmal cells, whose appearances in the biopsy smears llustrated in figs 1–6 A few workers have described ar cells in biopsy material Custer's (1949) case already been mentioned Tsevrenis (1947), in his iption of "leucoses with malignant cytology," shows with large atypical nuclei and vacuolated cytoplasm he names "leucoblastic cells of sarcomatous type" some less bizarre cells occurring in "reticulo sis" Moeschlin (1947) shows large cells of the type r discussion that he obtained from splenic puncture case of primary reticulosis of the liver and spleen, alls them "pathological reticulum cells" Bessis) describes these cells as cells of "histiosarcoma" reticulosarcoma" He describes the changes that can egarded as characteristic of sarcomatous change in cells These can be summarised as follows

The cells tend to be all similar in any one case

The cells are very variable in size, usually larger than l often enormous

The ratio of nucleus to cytoplasm is much larger than

4 The nucleus is very anomalous, often very large, with an inflated appearance, sometimes multiple, with more or less complete amitotic division, and vacuolar degeneration of the nucleus is common

5 The nucleoli are almost always abnormal—numerous, large, oddly shaped, and showing odd staining reactions

6 Abnormal mitosis is common.

7 The cytoplasm is often pale, almost always vacuolated

Bessis obtained these cells by puncture of an enlarged spleen or an actual tumour The bone marrow in his patients was normal, but there is little doubt that the description fits very well the cells found in the bone marrow of the patients described in this present paper

Whether or not we agree that the cells are in fact malignant, it is clear that the presence of such cells in the marrow indicates a disease that has usually a much more rapid course than the clinical state suggests, is notably resistant to any of the forms of treatment at present available, and has so far proved inevitably fatal The condition is here named "myeloid reticulosis" because this emphasises the one constant feature of the disease—involvement of the bone marrow—that can certainly be used for diagnosis during life The term reticulosis, rather than reticulosarcoma, is used because, although the cells fit the criteria given by Bessis (1948), histologically the changes are those that Robb Smith (1938) regards as characteristic of reticulosis—i e, there is proliferation of cells arising at many points, producing an apparent infiltration, but the destruction of stroma and the dissemination of cells by embolism that typify reticulosarcoma are not seen

If these patients present with a "blood" disease, the bone marrow biopsy that should be undertaken as part of the investigation will make the diagnosis clear But some of the patients do not present in this way at first, and the value of bone marrow biopsy in the investigation of obscure splenomegaly or infiltration of bones should be remembered

SUMMARY

Six cases are described characterised by infiltration of the bone marrow with abnormal types of reticulum cells

The clinical picture was variable, and the cases presented with an acute blood disease, an unexplained splenomegaly, or infiltration of bone marrow

The condition was often much more severe than the clinical state suggested, and the course was unexpectedly short

None of the cases responded to treatment, and all ended fatally

The condition has been named "myeloid reticulosis" because involvement of the bone marrow by abnormal reticulum cells was the only common feature

Case 2 was referred by Prof W F Gaisford and Dr H. B Marsden at the Royal Manchester Children's Hospital, case 3 by Dr J T Lewis, of Belfast City Hospital, and case 4 by Mr R A Bailey and Dr J Davson at Crumpsall Hospital, Manchester, to all those I am indebted for material and information. Cases 1, 5, and 6 were seen at Manchester Royal Infirmary under the care of Dr J F Wilkinson, director of the department of hæmatology

Progress —Radiotherapy was tried for relief of pain, but it had little effect on the general condition, and the patient died six weeks later

Case 5 —A girl, aged 14, had been vaguely unwell for about twelve months, and nothing definite had been found by her doctor A month before admission to hospital she had developed a pyrexial illness with stiffness of the neck and some temporary œdema of the neck , shortly afterwards a purpuric rash had appeared over the shoulders, upper arms, and breasts She had then been admitted to a local hospital, where she was found to have a very large spleen and some anæmia, with red cells 3,600,000 per c mm , Hb 11 8 g per 100 ml , and white cells 5200 per c mm (normal differential count) , platelets were also normal—200,000 per c mm There was intermittent pyrexia up to 102°F, and radiography of lungs, bones, and abdomen showed no abnormality , sternal marrow showed erythroblastic hyperplasia but no abnormal cells In view of these indefinite findings, she was transferred to Manchester Royal Infirmary three weeks later

On admission the purpuric rash was present as before , the spleen reached to within 3 cm of the iliac crest , the liver was not enlarged , and no enlarged lymph glands were found No other hæmorrhages were present , her first menstrual period had occurred nine weeks before without incident She was somewhat more anæmic, Hb being now 8 8 g per 100 ml , and the platelet count had fallen to 145,000 per c mm Radiography still showed no abnormality No evidence of tuberculous infection was found Marrow from a vertebral spine showed erythroblastic hyperplasia , in addition there were numerous plasma and reticulum cells, mostly normal types, but some of the reticulum cells appeared to contain some lipid material, rather like Gaucher's cells It was considered that this might be a type of lipoidosis, and arrangements were made for splenectomy In the meantime the purpura had faded but the platelet count remained between 70,000 and 100,000 per c mm

Operation (Mr H T Simmons) —The spleen, though very large, was removed without difficulty, and several small spleniculi also were removed , the liver appeared normal

Histological sections of the spleen showed none of the changes associated with lipoidoses , instead the pulp was infiltrated, not grossly, with curious and rather large cells with large vesicular nuclei and deeply staining cytoplasm , they were not myelocytes or lymphocytes and were unlike myeloblasts , there was some fibrosis of the spleen, and the malpighian bodies had pale hyperplastic centres The picture resembled Hodgkin's disease or some form of reticulosis more than anything else A section of the liver showed normal structure, but here and there were small collections of the curious cells seen in the spleen

Progress —The patient recovered well from the operation, and when she went home two weeks later she had no anæmia and the platelets were 628,000 per c mm She remained well for only four weeks Then the pyrexia recurred and the petechial rash appeared again She was readmitted to hospital two weeks later

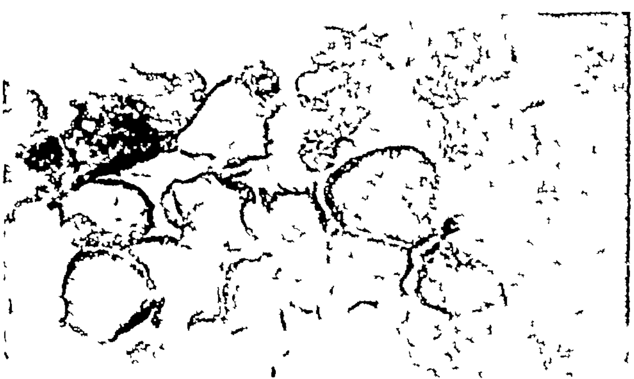

Fig 5 (case 5)—Bone-marrow Abnormal reticulum cells showing characteristic formation of groups or 'nests' of cells , the rounded irregular nuclei have a notably coarse chromatin pattern and the vacuolated cytoplasm is dark blue.

On readmission her temperature was 102°F, and she had an extensive petechial rash all over the trunk and breasts. The liver was now grossly enlarged to 10 cm below the costal margin Hb was 14 g per 100 ml , but leucocytes were now 27,400 per c mm (6% were immature granulocytes, 7% plasma cells, and 6% large unusual cells possibly monocytic, almost 50% of the nucleated cells counted were normoblasts), platelets were 115,000 per c mm In the bone marrow smears there were now many primitive reticulum cells arranged in clumps , most of the cells were about the size of the usual "blast" cell, but some were much larger (fig 5), normal granulocytes and erythroblasts were active as well The diagnosis was now clearly acute reticulosis

Treatment and Progress —Small doses of nitrogen mustard were given. The purpuric rash faded, but the liver remained enlarged, and the blood picture continued leuco-erythroblastic in type Later, primitive reticulum cells, like those in the marrow, appeared in the peripheral blood and accounted for 27 5% of the leucocytes present The patient was transfused and allowed to go home after three weeks Three weeks later she was much worse, with severe anæmia and extensive purpura , the liver was as large as before , lymph glands were not enlarged In spite of transfusion she died a week later No necropsy was allowed

Case 6 —A married woman, aged 56, was sent by her doctor to a local hospital because he had found an abdominal tumour The patient had noted gradually increasing abdominal distension for about nine months, and a month before had taken to her bed She had lost a lot of weight No hæmorrhages had occurred At the hospital the tumour was found to be an enlarged spleen, and, since the blood picture suggested a myeloid leukæmia, she was transferred to Manchester Royal Infirmary for treatment

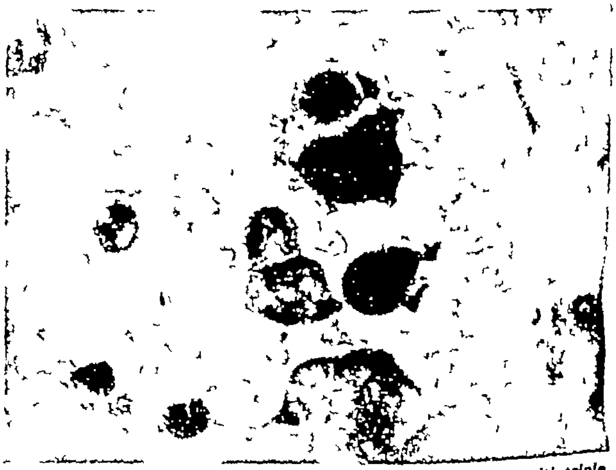

Fig 6 (case 6)—Bone-marrow Note syncytial type of cell with triple nucleus at top of field ; below there is a large irregular cell 22 μ in diameter, with much vacuolated cytoplasm , cytoplasm of cells is dark blue.

On admission she appeared thin and wasted There was no pyrexia No hæmorrhages were seen A few moderately enlarged lymph glands were present in the right axilla, but none elsewhere There were signs of pleural effusion at the base of the right lung The abdomen was greatly distended , the spleen was firm and enlarged, reaching almost to the pelvis , the liver was almost equally enlarged , no free peritoneal fluid was detected The urine was normal Radiography of the chest showed the right-sided pleural effusion but nothing else, and X ray films of long bones and the pelvis were normal

A *blood count* showed red cells 3,530,000 per c mm , Hb 7 6 g per 100 ml , white cells 13,200 per c mm (polymorphs 58%, lymphocytes 27%, monocytes 2%, eosinophils 8%, metamyelocytes 10%, ? myeloblasts 9 5%) , normoblasts were 3 per 200 white cells, and platelets were 240,000 per c.mm

The *bone marrow* (fig 6) contained many bizarre cells, large cells with large finely patterned nuclei and well marked nucleoli and deep blue, often vacuolated, cytoplasm , many of these cells contained 2–4 nuclei and some very large forms with several nuclei appeared more like syncytial masses

TABLE II—COMPLICATIONS ENCOUNTERED IN EACH 24 HOUR PERIOD, AND OCCASIONS ON WHICH CASEIN HYDROLYSATE WAS GIVEN (IN PARENTHESES)

Result	Duration of infusion			
	0–24 hours	24–48 hours	48–72 hours	More than 72 hours
No complications	246 (7)	160 (57)	78 (34)	51 (21)
Local sepsis	20 (8)	25 (19)	22 (15)	16 (11)
Generalised septicæmia	0	4 (3)	3 (2)	1 (1)
Venous thrombosis	10 (2)	12 (4)	12 (9)	4 (1)
Total complications	30 (10)	41 (26)	37 (26)	21 (13)

any other solution In a $2^1/_2\%$ solution this was given during the course of 194 infusions, and complications—either thrombosis or infection—followed in 75 of these

Table II records the number of intravenous infusions given in each twenty four hour period, the complications encountered, and the number of occasions on which casein hydrolysate was given The numbers in some of these groups are small, but, when they are grouped together, it is seen that the percentage incidence of complications was definitely greater among those treated with casein hydrolysate

Duration of therapy	*0–24 hr*	*24–48 hr*	*48–72 hr*	*More than 72 hr*
Treated with casein hydrolysate	59	31	43	38
Not treated with casein hydrolysate	8	13	20	21

The values of χ^2 are 38, 9 3, 6 1, 1 8, and all of these on 1 degree of freedom are significant, except the last Thus the treated cases develop at least double the percentage of complications in each period

As regards duration of treatment, the percentage distribution of cases treated with casein hydrolysate and cases not receiving casein hydrolysate was as follows

Duration of therapy	*0–24 hr*	*24–48 hr*	*48–72 hr*	*More than 72 hr*
Treated with casein hydrolysate	9	43	31	18
Not treated with casein hydrolysate	55	25	12	8

Comparison of the distribution of these two groups of cases gives a very large value of χ^2, the cases given casein hydrolysate being associated with greater duration of therapy

In assessing these results account should be taken of at least two factors First, casein hydrolysate was given to patients in whom vomiting persisted, and who were considered to be more ill than those accepting oral feeds Secondly, in over 90% of the cases it was given after the first twenty-four hours, and it is reasonable to assume that the longer the duration of the intravenous infusion the more likely is the vein to become thrombosed

The *pH of the solutions* used was also investigated as a possible cause of thrombosis by damage to the endothelium of the vein, and on one occasion a considerable variation of the pH of the stock solutions (prepared in the hospital dispensary) was found The actual pH was as follows

Solution	*pH*
N/5 saline solution and 5% dextrose	4 67
Half-strength Hartmann's solution	5 86
Darrow's solution	9 37

Solutions with well marked acidity or alkalinity may well contribute to the onset of thrombosis Hence the pH of the solutions used for intravenous therapy should be estimated regularly

The *sterility* of the solutions used was investigated several times, but no evidence of bacterial contamination was found Casein hydrolysate is known to be an excellent medium for bacterial growth, and care is always taken to use it fresh from the container If only part of the solution is required, the remainder is discarded

2 *Method*

In most cases a Bateman needle or a Keith needle was used, but for a few patients 'Polythene' tubing was employed The Regional Blood Transfusion Service infusion sets were used, and the limb was kept in a suitable position with a padded wooden splint to which the limb was fixed by bandage or strapping Our impression was that the skill of the operator, particularly his ability to set up the intravenous infusion within a few minutes, had a considerable influence on the complication rate When the vein was exposed for long periods or was found with difficulty—circumstances likely to cause local trauma and venous spasm—the complication rate was increased Subsequent interference with the infusion apparatus, either by "milking" the tubing or by "adjusting" the needle in the vein, similarly predisposed to complications

3 *Introduction of Infection*

As stated above, the solutions used were sterile, and the apparatus used was likewise found to be free from infection A number of complications followed the setting up of infusions by a particular operator, from whose hands a profuse growth of pathogenic bacteria was cultured To eliminate local infection at the infusion site, the setting up of an intravenous infusion should be regarded as a surgical procedure requiring the same technique as that used in the operating theatre No one with local sepsis of the hands should be allowed to put up an intravenous infusion unless wearing rubber gloves, and masks should be worn to prevent the spread of infection from the nasopharynx Similarly, any adjustment of the needle that may be required should be undertaken only with full surgical aseptic technique

TABLE III—RELATIONSHIP OF SITE OF INTRAVENOUS INFUSION TO COMPLICATION

Site of intravenous infusion	No of infusions	Local infection	Generalised spread	Thrombosis of vein without infection
Right ankle	163	25	3	10
„ knee	2			
wrist	36	2		4
elbow	119	12	1	3
Left ankle	164	23	3	15
knee	2	1		
wrist	32	2		1
elbow	105	16	1	5
Jugular veins	9			
Tibia	3	2		
Site not stated	40			
Total	664	83	8	38

Some workers have suggested that infusion sites in the lower limbs are more liable to infection because of possible contamination with excreta Table III sets out the site of the intravenous infusion in relation to the complications encountered The frequencies in some of the classes being small, the data were condensed into table IV, where (in the 624 infusions in which the site was recorded) "lower body" includes ankle, knee, and tibia, and "upper" body includes wrist, elbow, and jugular vein The expected frequencies in each class, calculated on the assumption that the site of intravenous infusion has no effect on the type of infection, are shown in parentheses after the observed frequencies The value of χ^2 is 7 421 on 3 degrees of freedom, and the 5% level of χ^2 is 7 815 hence the observed result is below significance but sufficiently near to make a relation between site and infection fairly likely Examination of the data indicates that the infection rate was higher when the infusions

COMPLICATIONS OF INTRAVENOUS FLUID THERAPY IN CHILDREN

R. McLaren Todd
M.A., M.D. Camb., M.R.C.P., D.C.H.

SENIOR LECTURER IN CHILD HEALTH, UNIVERSITY OF LIVERPOOL; PÆDIATRICIAN, ALDER HEY CHILDREN'S HOSPITAL, LIVERPOOL

The occurrence of fatal generalised septicæmia in three infants who had had intravenous infusions prompted this investigation, which covers all patients who received intravenous fluid replacement therapy at Alder Hey Children's Hospital, Liverpool, in 1949. Alder Hey is a general children's hospital to which children up to the age of fifteen with any type of medical or surgical condition, acute or chronic, are admitted. During 1949 the average number of beds and cots occupied was 586, and 8160 patients were admitted. Of the 332 (4%) children who received parenteral fluid therapy, 253 (76%) were infants in the first year of life. There were 192 males, of whom 39 (20%) died, and 140 females, of whom 28 (20%) died. The mortality rates of each age group were:

Age		*No. of cases*	*No. of deaths*	*Age*		*No. of cases*	*No. of deaths*

The conditions for which the children received intravenous therapy were diarrhœa and vomiting (211), pyloric stenosis (15), and miscellaneous medical (42) and surgical (64), most of the last-named being peritonitis resulting from appendicitis. The age groups and diagnoses are listed in table I.

METHOD

The total number of intravenous infusions given was 664, some patients receiving up to 7 infusions. A standard régime of fluid replacement was followed in almost all the patients with diarrhœa and vomiting, and in a majority of patients with other conditions; but this plan of treatment was occasionally altered to meet particular problems. The details of this basic régime are as follow:

1. During the first six hours' treatment, shock and hæmoconcentration are relieved by giving 20 ml. of plasma per lb. of expected body weight, mixed with 20 ml. of half-strength Hartmann's solution per lb. of expected body weight.
2. During the following twelve hours Darrow's solution (40 ml. per lb.) is given, followed by
3. $N/5$ saline solution and 5% dextrose (20 ml. per lb.) in the next six hours, making the total fluid intake in the first twenty-four hours 100 ml. per lb. of expected body weight.
4. When vomiting persists or diarrhœa is severe and the child is very reluctant to take oral feeds, 75 ml. of fluid per lb. is given intravenously during the second twenty-four hours. This fluid consists of $2^1/_2$% casein hydrolysate (60 ml. per lb.) and $N/5$ saline solution with 5% dextrose (15 ml. per lb.). Alternatively, if the patient accepts fluids by mouth, no casein hydrolysate is given, but the intravenous infusion is continued so that the total fluid intake (oral and parenteral) is 75 ml. per lb. The fluid offered by mouth is $N/5$ saline solution and 5% glucose in amounts increasing at each feed by a seventh of the calculated daily fluid requirement, so that the volume of the seventh feed offered in the form of glucose saline is 75 ml. per lb. of expected body weight. When the full fluid requirement is being taken, a seventh of the calculated milk requirement is offered during the following twenty-four hours, and this is increased by a seventh each day, so that the full calorie requirement (50 calories per lb.) is being offered on the seventh day.

INCIDENCE OF COMPLICATIONS

The number of complications encountered in 664 infusions was 132:

Complication	*No. of cases*
Local infection at the infusion site	83
Generalised infection (septicæmia)	8
Venous thrombosis without infection	38
Hepatitis	1
Circulatory overloading	1
Wrist drop	1

"Local infection at the infusion site" connotes the presence of pus and does not include slight erythema of the wound. "Venous thrombosis without infection" does not include minor degrees of œdema at the infusion site but implies more extensive œdema, often associated with a palpable thrombosed vein.

THROMBOSIS AND INFECTION

The possible factors contributing to the onset of venous thrombosis and local or generalised infection can be considered under five main headings: (1) the fluids used for intravenous therapy, (2) the method used, (3) the introduction of infection into the wound either during or after the infusion, (4) the nature and severity of the primary illness, and (5) the resistance of the infecting organisms to antibiotics.

1. *Fluids Used*

The number of occasions on which the various fluids were used was:

Plasma	211
Blood	90
Darrow's solution	304
N/5 saline solution and 5% glucose	427
Casydrol ($2^1/_2$%)	104
Hartmann's solution (half strength)	295

The complications encountered are set out in table II.

Our clinical impression was that complications were more often associated with casein hydrolysate than with

given, the respirations became rapid and laboured, slight cyanosis was present, the heart-rate was rapid, there was œdema of the chest wall, and the liver was enlarged. The intravenous infusion was immediately discontinued, and within a few hours the symptoms disappeared

To avoid circulatory overloading it is our practice to record the volume of fluid given intravenously at hourly intervals, and in this case the hourly volume of fluid given was not in excess of the calculated amount A possible explanation is the big difference between the expected weight (9 lb) and the actual weight (6 lb 5 oz) and the calculation of the fluid requirement from the expected weight It seems reasonable, where the actual and expected weights differ widely, to calculate the fluid requirements on a figure between these two weights

WRIST DROP

Case 3 —A boy aged eight months was given intravenous fluids to combat dehydration due to diarrhœa and vomiting The intravenous infusion was set up at the right elbow, and thirty six hours later the flow became slow and œdema of the arm and hand was noted The infusion was therefore discontinued, although there was no evidence of venous thrombosis or sepsis, and there was no œdema elsewhere The œdema of the arm and hand persisted for ten days, wrist-drop was present, and early contraction of the fingers developed. Œdema of the muscles of the arm with pressure upon the radial nerve caused by tight bandaging of the limb during the intravenous infusion was considered the most probable explanation. No special treatment was given, the œdema gradually subsided, and full movements of the wrist and fingers returned within three weeks

CONCLUSIONS

After 664 intravenous infusions 132 complications were encountered. About 1 patient in 5 developed venous thrombosis or sepsis Though the mortality directly attributable to these complications was small, efforts should be made to avoid them either by improving technique or by using alternative procedures Some workers regard subcutaneous infusions as a satisfactory alternative to intravenous therapy, especially when given with hyaluronidase (Gaisford and Evans 1949) In our experience the rate of absorption of subcutaneous fluids, even with hyaluronidase, is too slow to restore the blood volume sufficiently rapidly in severely " shocked " infants In these patients intravenous therapy is essential, and the alternative procedure of giving fluids intravenously, whether into scalp veins, jugular veins, or peripheral limb veins, by needle and syringe during the initial period of " shock " is reasonable in practised hands Personally, I consider this technique far more difficult to acquire than that of setting up an infusion by the " cut down " method , and, unless all patients requiring intravenous therapy are treated in a special unit by expert operators, it is impracticable In the " cut down " technique fewer complications will arise if strict asepsis is practised.

Intramedullary tibial infusions are sometimes given to children, but in our experience they are dangerous and are apt to cause even more serious complications than intravenous infusions

In patients who refuse oral feeds for any length of time, particularly infants under the age of six months, it is essential to supply proteins in some form intravenously to prevent serious liver disease—a condition not encountered in this series Undoubtedly casein hydrolysate, even in a $2^{1}/_{2}\%$ solution, contributes materially to the onset of venous thrombosis, but if this substance prevents liver damage its use is nevertheless justified

Because infection of the intravenous infusion wounds is so prevalent, workers in some centres give penicillin as a routine to all patients receiving intravenous therapy Penicillin resistant organisms were present in most of our cases, and if any antibiotic is to be used as a routine it seems more reasonable to give streptomycin

I wish to thank Prof. Norman B Capon for his help and advice, Dr E G Hall, for the bacteriological reports, and Mr R L Plackett, M.A , of the department of applied mathematics in the University of Liverpool, for the statistical analyses

GUY'S HOSPITAL, LONDON

Irregular clonic spasm of the diaphragm, or hiccup, is a common disorder in health, and its significance in disease is well recognised Tonic spasm of the diaphragm is seen in chronic form in the emphysematous and occasionally in hysteria, and may occur in rabies, tetanus, and strychnine poisoning The abnormality of the diaphragm here described differs from hiccup and tonic spasm in that rapid and rhythmic contractions occur in attacks To describe the striking movements observed in our patient the term diaphragmatic flutter immediately seemed most apt, and it was interesting to find that the term had been similarly used by other workers That an uncommon or rarely recognised condition in medicine has few pseudonyms is a tribute to its characteristic appearance Diaphragmatic flutter is easy to recognise if the possibility is kept in mind, but otherwise it may be mistaken for paroxysmal tachycardia, valvular disease, or ischæmic heart disease The following case illustrates the main features of this uncommon and benign abnormality

CASE RECORD

A married woman, aged 42, was referred to Guy's Hospital in April, 1950, by Dr M. Cowan, of Catford, who had treated her over the previous nine months for attacks diagnosed as paroxysmal tachycardia There had been no improvement with sedatives and digitalis, either in the frequency or the severity of the attacks On examining her in one of her bouts of ' palpitation ' Dr Cowan heard a to and fro murmur over the heart and provisionally diagnosed aortic regurgitation In the absence of a history of rheumatic fever, Wassermann and Kahn tests were done but proved negative , it was at this stage that the patient came to Guy s and was seen by one of us (C G B) as an outpatient

The Attacks —She described her attacks clearly They started suddenly and occurred during the day or night, though they did not wake her She was aware when they ended, though the end was not so abrupt as the onset At first, nine months before, they lasted 2 or 3 minutes and happened about once a week, but recently she had been having five or six a day, each lasting up to 10 minutes Exertion or emotion might precipitate an attack, but not constantly The attacks were accompanied by shortness of breath, precordial discomfort and rapid palpitation in the chest She would sit down when at home, or stand still in the street, until the palpitation stopped

On the history alone it is difficult to see how a diagnosis of paroxysmal tachycardia could be avoided An attack occurred, however, at this first attendance It was then noticed that there was a rhythmic movement of the abdominal wall which was faster than the pulse rate, though this was about 120 per min. Synchronous with the abdominal movement but not with the pulse or apex beat, was a to and fro type of murmur heard all over the præcordium and lower chest, maximal in the mid axillary line on both sides The heart was

TABLE IV—PERCENTAGE FREQUENCIES OF COMPLICATIONS IN UPPER AND LOWER PARTS OF THE BODY

Type of infection	Site of drip		Total
	Lower body	Upper body	
Local infection	51 (44 29)	32 (38 71)	83
Generalised spread	6 (4 27)	2 (3 73)	8
Thrombosis of vein	25 (20 28)	13 (17 72)	38
No infection	251 (264 16)	244 (230 84)	495
Total	333	291	624

were administered in the lower body This conclusion, however, should be treated with reserve, for the cases treated were very heterogenous

4 *Severity of Illness*

253 (76%) of the patients were twelve months of age or less, and 204 (80%) of these 253 had diarrhœa and vomiting An attempt has been made to assess the severity of the illness in relation to the complication rate following intravenous therapy The difficulties to be met in doing this are well known, but it was felt that those cases requiring intravenous therapy within twelve hours of admission should be considered severe cases

The data, classified according to the complications encountered and whether the intravenous infusion was administered before or after twelve hours, appear in table V The expected frequencies, calculated on the assumption that the complication rate was not affected by the time of administration of the intravenous infusion, are shown in parentheses after the observed frequencies The value of χ^2 is 11 109 on 3 degrees of freedom, and the 5% level of χ^2 is 7 815 Examination of the data indicates that the infection rate in the under twelve hours group is lower than in the over twelve hours group because of the much lower local infection rate But the nature of the cases treated, and the other possible factors involved, make such conclusions very unreliable

5 *Resistance of Infecting Organisms*

The infecting organisms in the 83 cases of local infection of the infusion wound and in the 8 cases of generalised septicæmia were as follows

A *Local Infection*		
Staph. aureus coagulase positive		
Penicillin sensitive	16	30
Penicillin insensitive streptomycin sensitive	6	
Penicillin insensitive streptomycin insensitive	8	
Mixed *Staph aureus* infections:		
Staph aureus and *Strep fæcalis*	1	8
Staph aureus and *B proteus*	3	
Staph aureus and *Bact coli*	4	
Bact. coli		7
Bact coli and *B proteus*		1
B proteus		1
Ps pyocyanea		1
Strep fæcalis		1
Pus sterile on culture		24
No swab taken		10
	Total	83
B *Generalised Infection*		
Staph aureus coagulase positive		
Penicillin sensitive	1	6
Penicillin insensitive, streptomycin sensitive	3	
Penicillin insensitive streptomycin insensitive	2	
Bact coli		2
	Total	8

In the local infection group the pus was sterile in 24 cases and no swab was taken in 10 cases From the remaining 49 cases a pure growth of coagulase positive *Staphylococcus aureus* was obtained in 30, and in almost half of these the organisms were insensitive to penicillin though some were sensitive to streptomycin From the 8 cases of generalised infection coagulase positive *Staph aureus* was isolated in 6, and in 5 of these the organism was penicillin insensitive

HEPATITIS

Lehane et al (1949) found 1 case of homologous serum jaundice in a series of 214 patients under the age of ten years who had been given blood or plasma transfusions Apley and Wallis (1948) reported 2 fatal cases of homologous serum jaundice in infancy, and concluded from a study of the literature that in infancy this complication is extremely rare Only 1 case of hepatitis following a transfusion of plasma or of blood occurred in the present series of 332 cases The jaundice appeared seventy days after plasma had been given, there was no history of contact with a case of infective hepatitis, and necropsy did not reveal any other cause for the jaundice

Case 1 —A girl, born on Nov 13, 1948, was admitted to hospital on March 28, 1949, with four days' history of diarrhœa and vomiting She was much dehydrated on admission, and intravenous fluids were given. The routine régime of fluid replacement was used and consisted of 560 ml of half strength plasma and Hartmann's solution in the first six hours, 560 ml of Darrow's solution in the following twelve hours, and 280 ml of *N*/5 saline solution and 5% glucose in the following six hours Oral feeding was begun after the first twenty four hours, but dehydration recurred, and the same amount of plasma, Darrow's solution, and *N*/5 saline solution as before were given during the subsequent twenty four hours. Graduated feeding was then started again, and the child made an uninterrupted recovery She was discharged twenty-one days after admission

TABLE V—COMPLICATIONS ENCOUNTERED (EXPECTED FREQUENCIES IN PARENTHESES) IN PATIENTS RECEIVING INTRAVENOUS THERAPY WITHIN OR AFTER 12 HOURS OF ADMISSION

Type of infection	Intravenous therapy		Total
	Within 12 hours	After 12 hours	
Local infection	17 (28 98)	48 (36 02)	65
Generalised spread	4 (3 57)	4 (4 43)	8
Thrombosis of vein	17 (15 60)	18 (19·40)	35
No infection	110 (99 86)	114 (124 14)	224
Total	148	184	332

On June 6, 1949 (49 days after discharge) she was readmitted with two days' history of vomiting Jaundice was present, but no other abnormal physical signs were noted Within forty eight hours she became drowsy, and tonic convulsions supervened Death took place on June 8 At necropsy the liver was normal in size, its surface was speckled bright red and yellow, and its consistence was normal on section Throughout the liver the pattern showed peripheral fatty change, with bright red areas in the centres of the lobules On microscopical section there was zonal necrosis which had left only a few surviving cells at the periphery of the lobule there was marked fat infiltration of the outer half of the lobule, and periportal infiltration of polymorphs, plasma cells, and round cells

CIRCULATORY OVERLOADING

Case 2 —A boy, born on March 10, 1949, was admitted on May 14, 1949, with a history of bronchopneumonia two weeks previously which had responded to penicillin, and diarrhœa and vomiting starting twenty four hours before admission He was dehydrated, and an intravenous infusion was given for the initial forty eight hours His condition improved, but a relapse occurred on May 22, and further intravenous therapy was given The fluid requirements were based upon the expected weight, which for the birth weight of 4 lb 13 oz was 9 lb The actual weight was 6 lb 5 oz. The fluids ordered were 360 ml of plasma in six hours 360 ml of Darrow's solution in twelve hours, and 180 ml of *N*/5 saline solution and 5% glucose in the following six hours The full volumes of plasma and Darrow's solution were given, but because the infusion was running slowly, only 80 ml of *N*/5 saline solution and 5% glucose was given In the following twenty four hours 675 ml of *N*/5 saline solution and 5% glucose was prescribed, but, when about 600 ml had been as happened with the peripatetic flutterer in America (Porter 1936 and others) Awareness of the diaphragmatic movement is surprisingly rare, and palpitation as a presenting symptom has only been reported in one case (Dowman 1927) apart from the present patient

Signs

The common sign is epigastric pulsation at a rate of 70–200 a minute, either regular or with slight variations in rate and amplitude, in the unilateral movement with tetany one upper quadrant alone moves Thoracic expansion is diminished or absent, but it can be produced voluntarily without influencing the flutter, as in our patient The thorax may show pulsation, in the patient described by Handron (1941) the excursions of the diaphragm were 6 in and shook the whole body

Bruits may be heard on auscultation of the chest, particularly the lower part, due either to the diaphragmatic movement or, more probably, to secondary effects in the lungs. They may be mistaken for heart sounds with a tic tac rhythm or, when irregular, with auricular fibrillation (Cain and Ware 1946), for the to-and-fro murmur of aortic disease (Levine and Harvey 1949), or for a pericardial friction rub (Porter 1936, Goodman 1941) The description (Porter 1936) of the noise as “shuffling” was particularly apt in our case When the common symptoms of breathlessness and pain are present, it is easy to see how heart disease may be diagnosed, until the diaphragmatic origin of the sounds is recognised by their low site, their lack of timing with the pulse or heart sounds, or obvious abdominal pulsation. Fluoroscopy clinches the diagnosis. Though other workers had failed to show any abnormalities in the electrocardiogram during an attack, Söderström (1950) demonstrated small rapid oscillations on both standard and unipolar leads which he thought were due to the diaphragmatic movements. Similar waves were seen in our case but were shown to be due to changes in pressure of the electrode. The only abnormality found in many investigations of these cases is an occasional fall in the alkali reserve due to protracted hyperventilation (Gamble et al. 1925, Handron 1941)

TREATMENT

When due to tetany, diaphragmatic flutter will respond to treatment of that condition. When it is the result of encephalitis lethargica, treatment can only be symptomatic. When it is a nervous tic it may disappear spontaneously, or may respond to explanation, reassurance, and re-education in the use of the diaphragm Sedatives are clearly useful in such treatment Harris and Scherf (1945) used quinidine in their case in an attempt to prolong the refractory period of the diaphragmatic muscle with apparent effect. Gamble et al. (1925) found that freezing the exposed phrenic nerves with ethyl chloride temporarily arrested the flutter, and “cures” are reported (Dowman 1927, Speirs 1929, Skillern 1931 Greene 1932 Handron 1941) by phrenic avulsion or division, surprisingly little disability results even when this is done on both sides In the itinerant patient in America both phrenic nerves were crushed or divided on several occasions. A satisfactory paralysis was achieved on the left side, but the right half of the diaphragm could still flutter when the case was last recorded—by Senter et al. (1950), who therefore suggested that an accessory phrenic nerve was present In a condition which is essentially benign and which may be temporary, such radical treatment is only indicated when very severe symptoms have not responded to simpler measures after a period of observation It would then seem reasonable first to do a phrenic crush, which could later be followed by a division of the nerve if disabling attacks of flutter returned

PARALYTIC POLIOMYELITIS FOLLOWING INJURY

A. Blair Harrington
M.D Aberd.
PRINCIPAL MEDICAL OFFICER, MINISTRY OF PENSIONS

In the last few years it has been established that in children recently submitted to tonsillectomy, poliomyelitis is especially likely to take the bulbar form, and it has been suggested that not only the site but also the incidence and severity of paralysis may be affected by prophylactic inoculations Geffen (1950) mentions a case in which appendicectomy was followed by abdominal paralysis

Horstmann (1950) states that, in her recent series, which included 248 cases of paralytic poliomyelitis, several of the patients had muscle weakness in limbs which had sustained trauma Otherwise, however, apart from the experimental work of Levinson et al. (1945), little has been written about the effect of direct local injury in poliomyelitis I have therefore taken an opportunity to review the records of 100 unselected cases of poliomyelitis acquired during service in the Armed Forces In 5 of these it was evident that trauma had preceded the paralysis The five case records are set out below

CASE RECORDS

Case 1 —On June 20, 1945, a soldier fell on his back while playing football. After a short rest he continued playing and finished the game His back was stiff and sore for a few days, but he did not go off duty On July 1 he had pains in the back, legs, and head. On July 3 he began to drag his left foot, and that evening his right leg felt weak.

When he was admitted to hospital on July 4 his neck was stiff, his left leg was tender and completely paralysed, and his right leg was very weak. He had retention of urine, which lasted ten days. Lumbar puncture produced cerebrospinal fluid (C.S.F.) under slightly increased pressure; clear, colourless, and containing 8 cells per c.mm. and 100 mg of protein per 100 ml. Culture proved sterile His temperature, which had risen to 101°F, reached normal on July 7 Radiography of the lumbosacral area and sacro-iliac joints on July 26 showed only a lumbosacral angle larger than normal.

Testing later confirmed the presence of slight weakness of the recti abdominis and erectores spinæ muscles. Paralysis of the obliqui externi abdominis muscles, however, remains The left leg too, is completely paralysed, but there has been a slight return of power in the right leg

not enlarged clinically, the sounds were normal, with no murmurs of intrinsic heart disease, and the blood pressure was 140/85 mm. Hg There were no signs of venous congestion, and the patient's distress was nervous rather than cardiac

Behind the X ray screen her heart was seen to be normal in shape and contour, but it was bouncing on the top of the diaphragm, both leaves of which were contracting rhythmically and violently at the rate of about 160 times a minute The term "flutter" seemed most apt to describe this odd behaviour of the diaphragm, and we found later that it had been thus described by others

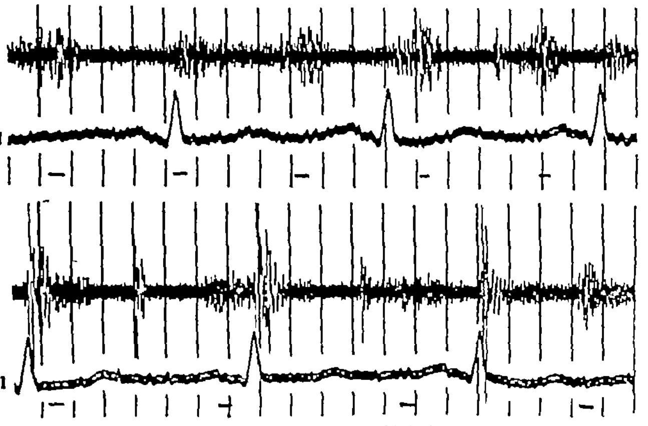
That this diaphragmatic flutter, and not heart-disease, was responsible for the patient's dramatic symptoms and signs was even more obvious on a second visit a few days later, when she was no longer nervous and her heart rate was only 70 per min In a further attack the dissociation between her pulse and her abdominal pulsation was very striking She was admitted for observation in July, 1950

Past History —The patient had had no serious illnesses, and she came of healthy stock She worked as a ward maid until her marriage at the age of 28 In 1942 she was "bombed out" three times, and she had been nervous ever since, she was easily upset and did not sleep well In 1946 she returned to part time work as a ward maid in addition to her own house work. She had no children There were no clear or unusual causes for worry or anxiety in her life

On examination no evidence of disease was found Her physique and weight were satisfactory She was slightly anæmic Hb 80%, red cells 4,200,000 and white cells 6500 per c mm (differential count normal) X ray examinations barium meal showed no diaphragmatic hernia or abnormality of stomach or duodenum, cholecystogram normal, lungs normal, no cardiac enlargement Serum calcium 10 8 mg and serum cholesterol 256 mg per 100 ml Alkali reserve 62 vols of CO_2 per 100 ml, with no reduction at the end of an attack

Electrocardiography showed a vertical heart with no abnormality in standard or unipolar leads During an attack an exploring electrode was placed in many positions, but abnormal tracings were obtained only at the mid point between the xiphisternum and umbilicus, this showed additional waves, irregular in shape and size, varying in rate from 190 to 320 per min similar waves could be produced by intermittent pressure on the electrode when the patient was not in an attack, showing that the abnormal waves did not result from the diaphragmatic flutter

When she was first in hospital, her attacks were as frequent as 6–8 a day but never occurred while she was asleep, they started insidiously or suddenly, and came on readily when she was examined During the attack she would lie flat on her back in bed and the pulsation of her abdominal wall could then be easily seen The rate of the pulsation in attacks was 160–240 per min, the rhythm was usually regular but occasional irregularities in rate and amplitude were seen (see figure) There was no thoracic movement, but she could take a deep breath or speak without altering the pulsation. There was no cyanosis during an attack but she was dyspnœic on walking or talking She felt some precordial discomfort, rather than pain, in the midline, but without the characteristic radiation of angina



Logarithmic sound tracings (Dr B G Wells): upper from right 5th interspace in mid-clavicular line lower from apex, both upper and lower with lead II of electrocardiograph Diaphragmatic flutter sounds are indicated by dashes and show alteration in rate 150 a minute in upper tracing with heart rate of 86 In tracing from apex the softer flutter sounds are overwhelmed by first and second heart sounds

The murmur could be heard all over her heart and lower thorax but was loudest in the mid axillary line, especially on the right, it had a to and fro rhythm, in time with the epigastric pulsation, it was medium pitched, roughish, and rustling, the term "shuffling" (Porter 1936) described it well. Dr B G Wells, who kindly came from St. Bartholomew's Hospital to take a phonocardiogram, demonstrated it graphically (see figure)

No trick movements would stop or abort the attacks, which lasted 4–10 minutes, and though they occasionally stopped suddenly they more often subsided gradually, particularly if the patient's attention was distracted by conversation or other interest

Progress —She was assured that she had no organic disease and was treated by simple explanation of the nervous mechanism, a routine sedative, and breathing exercises, with instruction in the full and proper use of her diaphragm On this regime her obvious nervousness decreased and the attacks diminished to about 3 short ones a day She has since attended as an outpatient, and though she still has attacks they bother her little, and she is leading a full and seemingly happy life

DISCUSSION

Flutter of the diaphragm is not a new observation, for it was described in 1722 by Leeuwenhoek Simonin and Chevigny (1916) give references in the French literature of the nineteenth century, when it was described as chorea of the diaphragm, Fox (1898) described the disorder in England, and since the first world war there have been scattered references to it on the Continent and in America

Ætiology

Diaphragmatic flutter has been reported equally in each sex and between the ages of 16 and 84 It may result from encephalitis lethargica (Gamble et al 1925, Kulenkamp 1926, Dowman 1927, Speirs 1929, Skillern 1931, Smith 1932) and is one of the central disorders of respiratory function reviewed by Marie et al. (1922) In 3 cases of tetany left sided contractions of the diaphragm synchronous with the heart-beat have been observed (Karelitz 1932, Widström 1944, Soderstrom 1945) during the actual disease, these were thought to result from irritability of the diaphragm Harris and Scherf (1945) noted similar movements of the diaphragm in operations on dogs, but they ceased when the left phrenic nerve was removed from contact with the heart or was severed Mr R C Brock tells us that he has not observed such movements during thoracic operations in man

The remaining cases reported, like our own, seem to be a form of tic Two cases have followed repeated abdominal operations, which are as likely to indicate an unstable personality of the patient as to support the suggestion that diaphragmatic adhesions are the cause of the flutter (Handron 1941, Smith 1932) Nervous and psychopathic features are common, and are well shown in an American patient who was the cause of no fewer than six separate reports (Porter 1936, Whitehead et al 1939, Goodman 1941, Cain and Ware 1946, Moore and Schoff 1947, Senter et al 1950)

Symptoms

Diaphragmatic flutter may be symptomless, particularly if it is one of several postencephalitic disturbances Breathlessness is the commonest complaint, occurring in attacks of sudden onset which may last from minutes to as long as seventeen days (Harris and Scherf 1945) Pain in the chest, felt at the site of diaphragmatic attachment of the ribs, in the epigastrium, or more often in the præcordium is common, it may radiate to the left shoulder or arm It is easy to see how this may give rise to a wrong diagnosis of myocardial ischæmia or infarction,

ENERALISED SCLERODERMA WITH INTESTINAL INVOLVEMENT

C BARRINGTON PROWSE
M.B Camb, M.R C.P
SICIAN, ROYAL SUSSEX COUNTY HOSPITAL, BRIGHTON

1945 Goetz, writing on the pathology of generalised oderma, concluded that "we are dealing with a emic disease neither solely nor primarily involving skin scleroderma' is only the obvious and striking ptom of a generalised disease and the most serious ptoms actually arise in the viscera." He suggested the term scleroderma should be abandoned "progressive systemic sclerosis" substituted it

here is ample justification for such a change, as a ly of the literature relating to the visceral lesions in roderma and acrosclerosis will show Various writers e dealt with the clinical, radiological, and pathological ects of its effects on the gastro intestinal tract, heart, gs, kidneys, bones, and muscles, and the vasomotor endocrine systems Hitherto, however, these reports e only attracted the attention of workers with a cial interest in such diseases, and too little importance s been attached to the responsibility of the general ysician for recognising their widespread nature

Dysphagia, Raynaud's phenomenon, calcinosis, and erodactyly are familiar "complications," but the fact at scleroderma and acrosclerosis may cause fatal, lminating disease of the bowel, heart, or lungs is less ell known, and it is the purpose of this communication set on record a further case in which death was clearly ue to sclerodermatous infiltration of the gastro intestinal act

Only 2 cases of intestinal involvement were recorded efore 1942 (Kraus 1925, Rake 1931) Hale and Schatzki 1944) described the radiological appearances of the gastro intestinal tract in 22 cases, in 4 of which the small ntestine was involved, and Goetz (1945) reported 6 cases in which an intestinal lesion was proved radio- logically or pathologically, in 1 of which paralytic ileus developed. Pugh, Kvale, and Margulies (1945) recorded a case with involvement of the small intestine demonstrated by radiography, and Lushbaugh Rubin, and Rothman (1948) described another in which scleroderma of the intestine proved fatal by causing gangrene of a segment of the colon. Bevans (1945), in a full account of the histological appearances in 2 fatal cases, described diffuse lymphocytic infiltration in the jejunum there were dense collagen fibrils in the submucosa, and atrophy of both muscle layers with fibrous tissue replacement She also commented on the thickness and whiteness of both layers of the peritoneum, and the presence of numerous adhesions between the viscera She concluded that muscle atrophy throughout the gastro intestinal tract is an integral part of the disease and is responsible for some of the symptoms and signs observed in life.

Gastro-intestinal features were prominent in the case recorded here There was a complaint of dysphagia, achalasia of the cardia slight dilatation of the œsophagus, and distension with air (as noted by Bourne 1949) were demonstrated radiologically and at necropsy characteristic changes were found at the lower end of the œsophagus Paralytic ileus developed in the terminal stages, plastic peritonitis was demonstrated post mortem, and histological examination of the small intestine showed extensive round-cell infiltration of the submucosa, and atrophy of all layers with an increase in collagenous tissue

"Scleroderma heart disease" was described by Weiss et al. (1943) in a review of 9 cases, all had signs and symptoms of heart-disease, cardiac enlargement, and electrocardiographic abnormalities, and 6 died in congestive failure Heine (1926), Brock (1934), Mathisen and Palmer (1947), and East and Oram (1947) have each described 1 patient with scleroderma who died as the result of cardiac involvement In the present case, breathlessness was a prominent symptom, the heart was enlarged and the electrocardiogram abnormal, and, though these signs and symptoms could not be attributed solely to sclerodermatous infiltration of the heart muscle, there can be no doubt that it played a part

It is more difficult to attribute pulmonary fibrosis with certainty to a sclerodermatous process But fibrosis of the lower lobes was observed by Goetz (1945), who described specific histological changes in and around the alveoli and in the blood-vessels, Jackman (1943) mentioned basal pulmonary fibrosis in his account of the radiological features of scleroderma and acrosclerosis, and Murphy et al. (1941) described a young negress with similar radiographic pulmonary changes, and noted particularly that this patient had no previous history of chest disease More recently Lloyd and Tonkin (1948) reviewed the literature relating to pulmonary fibrosis in generalised scleroderma and reported 4 cases of their own; and Church and Ellis (1950) reported 2 cases with cystic pulmonary fibrosis, and referred to 3 others described by Dostrovsky (1947)

The case to be described here first came under medical care with a pulmonary illness, but though it is tempting, in the light of the subsequent course, to postulate that sclerodermatous fibrosis of the lungs predisposed to the acute infection, this cannot be proved. Signs and symptoms of pulmonary fibrosis were present when I examined the patient two years later, and an X-ray picture showed dense basal shadows on both sides Histological sections revealed changes similar to those described by Goetz (1945) and Bevans (1945)

Asthenia, pigmentation, progressive loss of weight, hypotension, and personality change were other features of the case, and when crises of vomiting occurred the clinical picture suggested Addison's disease Osler first discussed the differential diagnosis between scleroderma and Addison's disease, it would seem that Simmonds's disease might present the same clinical features However, biochemical tests showed no disturbance of sodium metabolism and the pathologist noted no abnormality of the endocrine glands apart from the very small size of the pituitary body

CASE RECORD

A man of 66 was referred to me on April 2, 1948, by his doctor, who had only recently taken charge of him. He complained of lassitude palpitations breathlessness, pains all over his body, and numbness of his fingers and of the left side of his face He stated that in May, 1946 he had a febrile illness, diagnosed as right-sided 'pneumonia and pleurisy,' which was treated for six weeks in a cottage hospital. Two weeks later he fell ill again and returned to hospital for another three weeks with left-sided 'pneumonia and pleurisy' X ray examination at that time revealed emphysema and chronic bronchitis, and later a small collection of fluid at the right base

After these episodes he failed to regain his normal health, and though never acutely ill he felt vaguely unwell. He noticed that his fingers tended to grow numb, and frequently turned bluish black for long periods, particularly during cold weather he also found that the skin over his hands was becoming tight Accordingly, in May 1947, he sought medical advice and was admitted to a 'clinic' for investigation. It is not known what diagnosis was made, but colonic lavage and fasting were advised This treatment he refused at first, but submitted to in the following November while undergoing it he lost 2 st in weight but he recovered some of this after returning home The symptoms for which he had sought advice remained unchanged, and in addition he noticed increasing tightness of the skin of his face with impairment of sensation over the left cheek and gums.

The past, personal, and family histories were negative.

Case 2 —A lance bombardier injured the lower part of his spine on Aug 1, 1945, and developed very severe pain in the region of his coccyx He had several uncomfortable nights before it subsided On Aug 5 the pain returned and was worse in certain positions There was also a throbbing temporal headache Next day, while walking, he found that his left leg was weak and he could not control it On examination all the leg reflexes were absent, and the patient's temperature was 99 8°F Next day his temperature rose to 101 4°F, his neck was rigid, the lower part of his abdomen was weak, and both lower abdominal reflexes and knee jerks were absent There was no power in the left quadriceps, adductors, or hamstrings, and these muscles were also very weak on the right There was little power below the knee on either side No sensory loss was recorded Lumbar puncture on Aug 7 produced clear C S F not under increased pressure There were 30 cells per c mm , but there is no record of any test for protein Retention of urine began on Aug 10 and required catheterisation. Dysuria continued for the next ten days

Examination in 1947 showed a complete flaccid paralysis of the left leg, which was thin, cold, and blue There was some improvement in all muscle groups in the right leg, and the abdominal muscles had recovered

Case 3 —While playing hockey on Nov 5, 1943, an aircraftman collided with another player and fell on the right side of his head At the same moment he was struck a heavy blow on the right shoulder by his opponent s stick He felt slightly dazed for a moment but got up and remembers finishing the game

On the evening of Nov 7 he developed a severe headache, and next day he had sweating, malaise, anorexia, and constipation He vomited several times and had a temperature of 101 8°F and pulse rate 106 His neck was stiff and ached, and he then found that he could hardly move his right arm His left arm was slightly weaker than normal , next day the weakness had spread to his right leg Lumbar puncture on Nov 8 showed clear C S.F under normal pressure and containing an excess of small lymphocytes By Aug 19 the left arm and right leg had almost recovered, but flaccid palsy of the right arm persisted

Early the next year the arm showed only some power in the finger flexors and flexor carpi radialis and ulnaris muscles All other muscles tested, including those of the shoulder girdle, were paralysed The other limbs and trunk were normal

Case 4 —On July 26, 1943, an aircraftman jumped off a lorry and landed on his heels and his back He felt a sudden pain " stabbing upwards " in his thighs After a day in bed because of headache he felt quite well On July 31 he had an aching pain in the back and thighs, stiffness of the neck, and general malaise He thought he had a cold and stayed in bed for the day On Aug 2, on attempting to get up, he found there was no power in his legs

On examination two days later his lower limbs were flaccid and tender, and all tendon reflexes were absent There was no sensory loss He was constipated, and on Aug 5 he developed retention of urine and had to be catheterised until Aug 7 On Aug 9 the C S.F was clear and showed 8 cells per c mm and 30 mg of protein per 100 ml It was sterile on culture, and Lange's curve and the Wassermann reaction were negative Radiography of the dorsolumbar spine on that date showed no abnormality

He was febrile and developed oliguria between Aug 9 and 14 , this may have been related to his poor fluid intake, for urinary flow was established again by Aug 16 after a glucose saline drip had been set up Examination then showed that in addition he had weakness of the lower abdominal and lower intercostal muscles On further lumbar puncture on Aug 30 the C S.F contained 250 mg of protein per 100 ml and only 2 lymphocytes per c.mm

When examined in February, 1944, he had flaccid paralysis of the right rectus abdominis, lower intercostals, and lower fibres of the erectores spinæ muscles There was moderate weakness of these muscles on the left side but both legs were completely paralysed All tendon and shin reflexes were absent below the costal margins There was no sensory loss or difficulty of control of urine or fæces

Case 5 —A driver was admitted to hospital on Nov 7, 1944 He had a perianal abscess, and this was opened shortly after admission, but a sinus formed Smears and culture of the discharge showed *Staphylococcus albus* only (*Corynebacterium diphtheriæ* was never found by direct smears or on culture) Pains in the back appeared on Nov 11 when the abscess had been incised, and on Nov 13 weakness suddenly developed in the legs , the left rapidly became completely paralysed, and only flexion and extension at the right knee remained Lumbar puncture then showed 380 red cells and 10 lymphocytes per c mm , 35 mg of protein per 100 ml., 690 mg of chloride per 100 ml , and no growth on culture The temperature rose to 100°F next day

There has been slight improvement in his condition since When examined recently his left leg was paralysed except for weak flexion movements at his left knee and hip Knee and hip movements of the right leg were fairly strong, but there was complete flaccid palsy below the knee, with clawing of the toes Bladder control was normal At no time was there any sensory loss

DISCUSSION

Horstmann and Paul (1947) emphasise the variation in the interval between the apparent exposure to the virus and the onset of symptoms , they cite extremes of three days and five weeks Clearly there is a latent period after infection, and they mention a case in which polio myelitis virus was detected in the stools nineteen days before the patient developed paralysis

In 4 of the 5 cases described above, the disease appeared within five days of the injury Apparently trauma upsets the balance between the virus and the host and precipitates the disease The effect seems similar to that of fatigue, which, as Ritchie Russell (1947, 1949) has shown, provokes paralysis, which may select the muscles most used

Since neither the time nor the route of virus invasion of the central nervous system is yet properly known, attempts to explain the effect of local trauma can only be speculative There do, however, seem to be two chief possibilities either the local injury opens up some pathways of infection to the spinal cord, or else the effect of local trauma is to alter the spinal-cord cell physiology in such a way as to reduce resistance to the virus, which may be already established in the cord

SUMMARY

Of 100 unselected cases of paralytic poliomyelitis 5 had a history of trauma which preceded by a few days the appearance of paralytic poliomyelitis

In each of these cases paralysis appeared in muscles closely related to the site of the trauma

Possible factors in the production of this paralysis are briefly discussed

I should like to thank Dr W Ritchie Russell for his helpful criticism, and the Director General, Medical Services, Ministry of Pensions, for permission to publish.

"... we find ourselves forced to the conclusion that we must have better and more mature individuals filling the positions of responsibility in every country if our vaunted civilization is to advance and not be swamped by all the primitive urges of hate, aggression, domination and the other unlovely characteristics It is, therefore, a matter of great urgency that we should have everywhere, in local communities, on civic councils and in the various societies which affect us, men and women who are better balanced and more in tune with their fellows Every one of us has something to contribute, not merely to our immediate entourage, but through them to the wider councils of the community and ultimately to the affairs of state"—Dr J R Rees in his foreword to the *Health of the Mind* (3rd ed , London, 1951)

Some widening of the distal 4 in of the œsophagus and a white opacity of the mucosal lining in the distal half Plastic peritonitis, with coils of bowel adherent to one another and to parietal peritoneum by fine adhesions Lymphatics visible leaving the small intestine and entering the mesentery Liver not enlarged but excess fat present Adrenals normal, apart from post-mortem changes Pancreas, kidneys, gall bladder, bladder, prostate, and spleen normal

Microscopical Appearances

Skin—The epidermis is thinned The dermis consists of relatively acellular collagenous tissue, and there is a little round cell infiltration.

Lungs (fig 3)—The original pathology is obscured by bronchopneumonia, but there is marked interstitial fibrosis with thickening of the alveolar walls Some of the vessels show intimal thickening with diminution in the size of the lumen.

Intestine (fig 4)—The wall of the small intestine shows extensive round cell infiltration of the submucosa There is some atrophy of all the layers and an increase of collagenous tissue

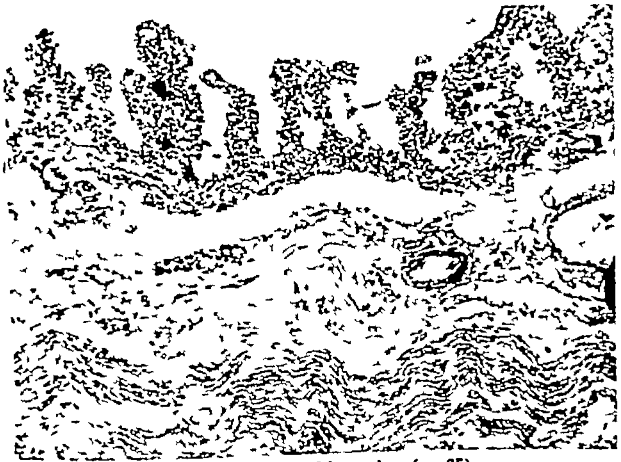

Fig 4—Section of intestine (× 85)

Heart—The pericardium is infiltrated with polymorphs and round cells The myocardium shows some perivascular fibrosis

SUMMARY

A case of scleroderma is described with widespread visceral lesions, all of which produced signs or symptoms and contributed to the fatal result Particular stress is laid on the intestinal features of the case—firstly because death eventually resulted from paralytic ileus, and secondly because the effects of scleroderma on the intestine have seldom been reported

My thanks are due to Dr L R Janes for the necropsy report, to Dr R W P Johnson for the histological notes, and to Dr S A Belshaw for his careful records of the case

EXPERIMENTS ON FAT ABSORPTION IN A CASE OF CHYLOTHORAX

W H R Auld
M B Aberd
ASSISTANT, DEPARTMENT OF CLINICAL CHEMISTRY, UNIVERSITY OF ABERDEEN

C D Needham
M D Lond, M R C P
ASSISTANT PHYSICIAN, ROYAL INFIRMARY, ABERDEEN

After about seventy years' intermittent research, the mechanism of the intestinal absorption of fat still remains unknown The work of Frazer (1943, 1946, 1947) and his colleagues has added considerable information, but their conclusions are not yet everywhere accepted They have studied fat absorption in all phases—intraluminar, intramural, and distributive (Frazer 1946)—in a large number of experiments and have advanced their partition hypothesis This postulates that not only fatty acids but also unhydrolysed triglyceride fat can be absorbed as such from the small intestine, and that they follow different paths, fatty acids being mainly absorbed into the portal circulation for transport to the liver, whereas neutral fat travels via the lacteals and thoracic duct to the systemic circulation and thence to the storage depots In support of this they have described experiments (Frazer 1943) in which they fed rats with fats stained with Sudan IV They found that in the animals consuming a neutral fat the dye accumulated in the fat storage depots throughout the body, whereas in those consuming the equivalent fat in the form of the products of hydrolysis—i e, fatty acid and glycerol—the dye was deposited mainly in the liver

Much of the work on this subject has been done on laboratory animals In man investigations have been confined mainly to fat-excretion and fat balance studies, to qualitative intraluminar changes while absorption is taking place, and to changes in the fat content of venous blood, usually systemic In the one case in which portal blood was examined (Sherlock and Walshe 1946) no increase in fat content could be demonstrated after feeding butter with and without added lipase, but their patient had hepatic cirrhosis, a fat balance test suggested that fat absorption was defective, and the systemic blood fat level did not rise

PRESENT STUDY

A male patient, aged 32, came under observation because of a non traumatic chylothorax of unknown origin There seemed to be a communication between a lymphatic channel and the left thoracic cavity, and chyle accumulated there at a constant rate of about 600 ml a day The clinical details and the management of the patient will be published elsewhere An opportunity was taken of using this case to test Frazer's hypothesis and to supplement his work with stained fats in a rather different fashion Although the ingestion of neutral fat stained with Sudan III has been used for many years as a diagnostic test to differentiate chylous effusions in the thorax or peritoneal cavity from pseudo chylous effusions where no communication exists with the lymphatic channels, we have not been able to find any report on the effect of giving split fat under the same conditions

The investigation lasted 14 days, during which we made three experiments In each the patient was fed a split or unsplit fat stained with a known quantity of Sudan III, and the dye recovered from the pleural cavity was estimated quantitatively Maximal recovery was achieved by paracentesis under fluoroscopic control to remove all but the last ounce of fluid During the investigation the patient received an ordinary ward

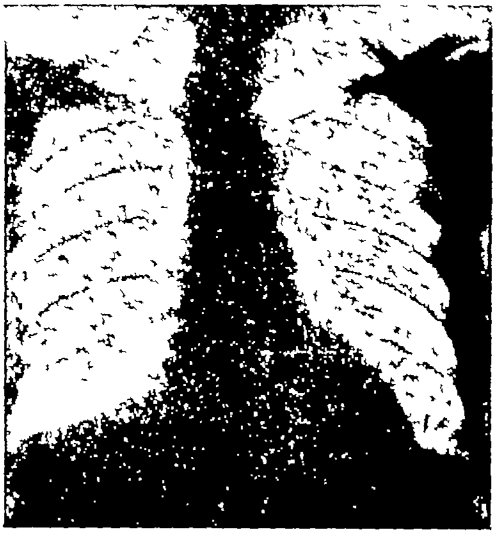

Fig 1 (March 19, 1948)—Heavy abnormal shadowing at both lung bases, right more than left. Slight general enlargement of left and right ventricles, aorta unfolded

His appearance was consistent with his stated age He was slightly built, and his thinness was accentuated by the tightness with which the shiny and pigmented skin was drawn over the malar bones, around the mouth, across the chest, and about the hands and forearms, he did not like smiling because it hurt him Second degree clubbing of the fingers and toes was present, and some fingers of each hand were white or blue Pulmonary ventilation was limited by emphysema and fixity of the thoracic cage, the skin, and the subcutaneous tissues, movement, air-entry, and resonance were impaired at the left base, and fine râles were heard in both lower lobes The heart was a little enlarged, its sounds were normal, and there were no murmurs, but extrasystoles were noted, the blood pressure was 112/80 mm Hg The tongue was furred but otherwise normal, there was no pigmentation of the buccal mucous membrane Abdominal examination was negative, and the testes normal

A provisional diagnosis of scleroderma was made, and this was later confirmed by skin biopsy Investigation showed

Blood-count —Red cells 5 000 000, Hb 86% colour index 0 86 white cells 12 500 polymorphs 68% eosinophils 1%, monocytes 2% lymphocytes 28%, basophils 1%

Erythrocyte sedimentation rate —27 mm in first hour

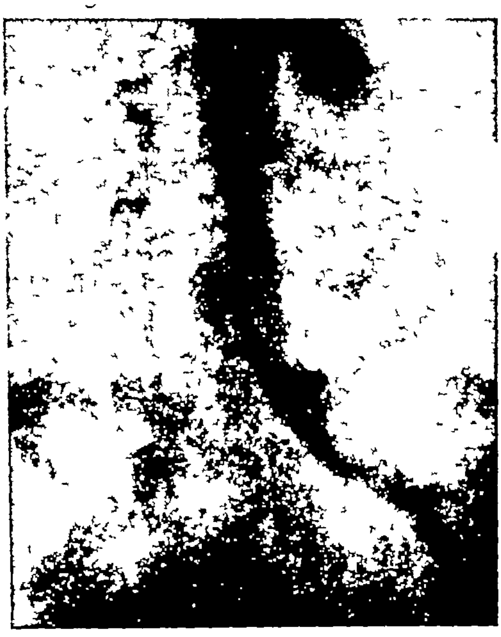

Fig 2 (April 9, 1948)—Barium swallow Achalasia of cardia. Slight general dilatation of œsophagus which is distended with air

Plasma proteins —Total 7 5 g per 100 ml Albumin 4 4 globulin 3 1 Albumin globulin ratio 1 4 1 0

Blood cholesterol —128 mg per 100 ml

Plasma chlorides —590 mg NaCl per 100 ml

Blood urea —26 mg per 100 ml

Radiography of the chest (fig 1) showed emphysema and chronic bronchitis with dense shadows at both bases, particularly the right Slight general enlargement of both ventricles was evident, the aorta was unfolded and atheromatous A barium swallow (fig 2) showed achalasia of the cardia and slight general enlargement of the œsophagus the appearances suggested chronic œsophagitis Radiography of the hands revealed nothing abnormal Electrocardiography showed sinus rhythm, rate 60, ventricular extrasystoles, left axis deviation, and some splintering but no widening of initial deflections, with T waves flat in all leads, inverted in lead III

On April 11 the patient developed a mild pyrexia, and two days later he complained of cough and abdominal pain with vomiting signs of basal bronchitis appeared, but resolved on penicillin therapy He became better in himself during the next few days, but on April 23 vomiting recommenced, and was accompanied by abdominal distension and absolute constipation paralytic ileus was diagnosed A course of acetylcholine and enemata relieved the obstructive symptoms, and general improvement followed again For almost a month he remained fairly well, having a good appetite and normal bowel actions, the only untoward incidents were bouts of dyspnœa and palpitation, almost certainly of emotional origin, and a further fall in blood pressure to 80/60 During this month an attempt was made to treat the scleroderma by massage and local applications to the hands, forearms, and chest, and with thyroid extract, gr $^{1}/_{3}$ b d, and dihydrotachysterol min 5 t d s He noticed an improvement in the resilience of the skin over his forearms and hands, but no objective changes were observed Moreover, in spite of symptomatic improvement, he continued to lose weight, for this reason thyroid medication was discontinued after two weeks

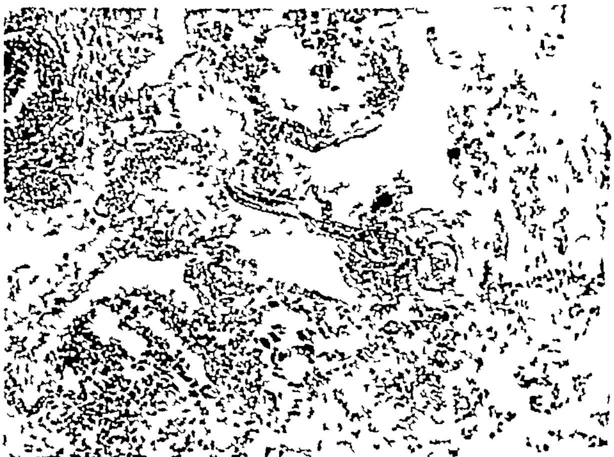

Fig 3—Section of lung (× 120) The vermiform object in the centre is a cotton fibre in the mounting medium

On June 27 the bowels again ceased to work, and two days later vomiting and hiccup with abdominal pain and distension returned Acetylcholine was given again but with little effect, he became progressively weaker, developed hypostatic pneumonia, and died on July 13

POST MORTEM FINDINGS

Macroscopic Appearances

Extreme emaciation Considerable pigmentation of skin Scleroderma of skin of fingers, hands, and lips Clubbing of toes and fingers

Brain normal Pituitary body very small Tongue, mouth, and neck normal Thyroid small but normal in appearance

Fine adhesions obliterated both pleural cavities Bilateral bronchiectasis of both lower lobes with confluent bronchopneumonia Heart weighed 9 oz Pericardial sac obliterated by fine adhesions Muscle wasted, yellowish in colour Valves normal save for some atheroma at base of mitral cusps, and small ulcerated areas on tricuspid valve Chordæ not thickened or shortened Aorta atheromatous, especially abdominal portion.

What factors determine the different courses taken are not clear The physical state of the material being absorbed may play a part, for, according to Frazer (1947), the neutral fat is absorbed in particulate form of 0 5 µ or less in diameter, whereas fatty acid is in the molecular state as a water soluble complex One might not be surprised that the neutral fat droplets should find their way into the readily permeable lymphatics, but it is difficult to see what prevents the appearance of the more freely diffusible fatty acids there Bloom et al. (1950) feeding C^{14} labelled fats to rats have recovered from thoracic duct fistulæ 58–85% of the isotope when given in neutral fat, and 70–92% when given in fatty acid. Further work is needed to clarify the relation of these findings to those of Frazer and to our observations

The Chylous Fluid

The fluid was odourless, milky white, and formed a delicate clot on standing A cream rose to the surface, especially in the specimens with a high content of fat Samples kept at room temperature without any preservatives showed no signs of bacterial growth even after several weeks The fluid contained polymorphs and lymphocytes but no red cells The total content of protein was 2 2–4 2 g per 100 ml, representing a loss of about 20 g a day from the body It is thus not surprising that signs of protein depletion with loss of weight and œdema sometimes appear as a result of chylothorax, especially if the leak is more complete than in the present case and if no steps are taken to supplement the diet

A chemical analysis of the lipid constituents of two specimens of fluid is given in the accompanying table

LIPID CONSTITUENTS OF CHYLE RECOVERED

Specimen	Free fatty acid titrated against standard alcoholic NaOH (factor 26 8) (mg per 100 ml)	Phospholipid (Hack 1947) (mg per 100 ml.)			Cholesterol (Bloor 1916) (mg per 100 ml)	Neutral fat (by difference) (g per 100 ml)	Total lipid (ether soluble fraction purified with petroleum ether) (g per 100 ml)
		Lecithins and cephalins	Sphingomyelin	Total			
1	214	233	32	265	120	2 12	2 72
2	100	206 5	35 5	242	155	1 35	1 85

The greater part of this is in the form of neutral fat and may vary within wide limits according to the consumption of fat by the individual On a greatly restricted intake of fat it may be reduced to 0 3 g % (Reiser 1937) Of interest is the unexpected concentration of fatty acid in the free titratable form Possibly this is an artefact derived from lipolysis of neutral fat on standing, although sampling and initial treatment took place in a very short time after the specimens were obtained An even higher concentration, 730 mg per 100 ml, has been found by other workers (Dittebrandt et al 1943) The remarkable resistance of chyle to infection is probably related to this high content of fatty acid The total amount of phospholipid falls within the normal concentration for plasma, as does the concentration of sphingomyelin Attempts to estimate the choline containing fraction by the reineckate method (Hack 1947) were abandoned owing to inconstant recoveries of choline reineckate from the same sample and from a standard solution of choline Although Swift and Neuhof (1946) have found the total cholesterol level low in comparison with normal plasma, this was no so in the specimens examined from this patient

SUMMARY

The effects of feeding fats stained with Sudan III were observed in a patient with non traumatic chylothorax

When stained neutral fat was given, a substantial amount of dye was recovered from the chylothorax, whereas, when the equivalent amounts of stained fatty acid and glycerol were given, no dye was recovered in one instance, and only a small amount in another

The findings support Frazer's hypothesis on the absorption of fat

An analysis of some of the lipid constituents of chyle was made

We wish to thank Dr John Green for his valuable assistance

COLONIC REPLACEMENT OF THE STOMACH

JAMES MORONEY
M.B Lpool, F.R C.S
SURGEON BROADGREEN HOSPITAL LIVERPOOL, AND
CLATTERBRIDGE GENERAL HOSPITAL, CHESHIRE

THIS is a preliminary account of a method of surgical treatment which I have devised for peptic ulcer and persistent post gastrectomy symptoms My objects in this paper are to set forth the principles on which it is based, and to give a short account of the evidence in support of the use of a tissue so far not employed in gastric surgery Of 22 patients (20 with peptic ulcer and 2 with post gastrectomy symptoms) submitted to operation, all have made satisfactory recoveries and all are very well The history of the treatment of peptic ulcer is strewn with similar accounts of such immediate success, and this optimism seems to be as characteristic as spontaneous remission of symptoms is characteristic of the disease For the final assessment of the value of treatment, careful follow up and the passage of time are necessary

EFFECTS OF SUBTOTAL GASTRECTOMY

Subtotal gastrectomy with removal of the pylorus is probably the most widely practised surgical measure for the relief of gastric and duodenal ulcer It gives the lowest proportion of recurrent or stomal ulceration, but this is none the less probably about 4% (*Lancet* 1950) Careful postoperative observation reveals such symptoms as failure to gain weight, fullness after a moderate sized meal and bilious vomiting, " dumping symptoms," and steatorrhœa, and various forms of malnutrition Post gastrectomy disabilities have been reported by Muir (1949) at some time in 75% of patients, and 34% were considerably handicapped Some patients (not many) are worse, others have exchanged ulcer symptoms for different symptoms Important, too, is the fact that after so radical an operation there can be no restoration of the *status quo ante*, and the field of surgical choice is limited, difficult, and uncertain

In addition to the secretion of an acid juice the stomach has other functions, among the most obvious of which are those of retaining a meal for some hours after eating, macerating it, and then passing it gradually to the duodenum After subtotal gastrectomy the gastric stump is usually anastomosed to the jejunum and the duodenal stump is closed The result is

1 The duodenum (10 in) and the greater portion of the first foot of jejunum are excluded from the food canal It is an established fact that there is a gradient of resistance in

diet except for the 14 hours before, and 24 hours after, the start of each test, when fat was withheld. Each experiment began in the morning 2 hours after a light fat-free breakfast. The pleural cavity was partially emptied before each experiment. A large collection might have exerted some back pressure on the ruptured vessel and reduced the flow of chyle, whereas complete evacuation would have rendered subsequent aspirations in the next few hours difficult. Each test dose was prepared by dissolving Sudan III 50 mg in the fat and, after having made certain that no particles remained in suspension, administering this through a Ryle's tube.

Estimation of Sudan III

Solutions of 0·1, 0·2, 0·3, and 0·4 mg per 100 ml of Sudan III in chyle were prepared by adding 0·5, 1·0, 1·5, and 2·0 ml of a 10 mg per 100 ml solution of Sudan III in ethyl alcohol to 50 ml samples from a large collection of chyle removed before any dye had been given. These were evaporated to dryness at 60°C and the residues extracted for 6 hours in a Soxhlet apparatus with ether. The ether residues dissolved in 20 ml of benzene served as standards.

Each collection of fluid was estimated separately for its dye content, a 50 ml aliquot being taken within a short time of withdrawal, for, on standing, the stained fat separated to the top like cream, and after this had occurred it was difficult to re-establish a homogeneous mixture. After drying and ether extraction the ether residue was dissolved in 20 ml of benzene and compared with the nearest standard in a visual colorimeter, an Ilford spectrum yellow-green (no. 605) filter being used.

EXPERIMENTS

Experiment 1. Oleic Acid and Glycerol

Specimens of chylous fluid were withdrawn from the thoracic cavity before, and 1, 2, 4, and 48 hours after, the administration of the mixture of 20 ml of stained oleic acid (*B.P.*) and 5 ml of glycerol. No staining took place in any of the specimens, so far as could be judged by direct inspection and by ether extraction, and it was concluded that little or no dye had reached the chylothorax.

Experiment 2. Neutral Fat

Immediately after the removal of the last unstained specimen in experiment 1, 20 ml of stained olive oil was given. Staining of the chylous fluid was apparent 3 hours later, and 5 hours after the fat had been given 2·70 litres of pink chyle had been aspirated. After 3 days a further aspiration was done under fluoroscopic control to empty the pleural cavity completely of 3·54 litres of pink chyle. In all, 10·40 mg of Sudan III was recovered.

Experiment 3. Oleic Acid and Glycerol (Repeat)

Experiment 1 was repeated in view of the persistent absence of dye from the chyle. This was done 6 days after the start of experiment 2. Since the original dose of fatty acid had produced some nausea, the 50 mg of Sudan III was given dissolved in 10 ml of oleic acid with 2·5 ml of glycerol. On this occasion a preliminary specimen and specimens removed 2 and 4 hours afterwards were again unstained. At $6^{1}/_{3}$ hours the pleural cavity was emptied of 2·64 litres of unstained fluid under fluoroscopic control. At 8 hours the patient inadvertently received a quantity of neutral fat in the form of butter and an egg for his tea. Next morning only 390 ml of fluid could be aspirated, but fluoroscopy was not used. The chyle was then definitely pink. After another 5 days the chest was emptied of a further 3 litres, which showed only the barest discernible trace of dye. The total amount of dye recovered during this period was 2·55 mg.

Any further experiment was rendered impossible by a change in the fluid. It had hitherto been typically chylous, but it had now become thin, slightly milky, and yellowish tinged with red owing to numerous red blood cells. A pleural reaction due to numerous paracenteses seemed to have developed. The fluid was, and remained, sterile on culture.

A week later thoracotomy was done, and a fatty fibrous layer covering the visceral and diaphragmatic pleural surfaces was removed. Subsequently the patient made a good recovery without any recurrence of chylothorax.

DISCUSSION

The hourly flow of lymph from the abdomen and lower extremities has been estimated at 60 to 190 ml. in man (Yater 1935), but there is no certainty that in any of the cases the total amount had been recovered. The volume collecting in our patient's pleural cavity averaged 600 ml per 24 hours—i.e., considerably less than the smallest estimate for the total flow through the thoracic duct. It is well recognised that the thoracic duct passing upwards from the cisterna chyli may consist not of a single structure but of a ramification of several vessels which may, moreover, enter the venous system at different points. It seems likely that the anatomical arrangement was such in this case, and that the ruptured vessel transported only part of the chyle from the abdomen. If we take the recovery of dye in experiment 2 (21%) as an indication of the percentage of the neutral fat which passed through the affected vessel, the absorption and distribution of triglyceride fat seem mainly, though not necessarily wholly, to take place by the chylolymphatic route. Any not thus accounted for would, according to Frazer, constitute the hydrolysed fraction absorbed by the portal system.

Of greater significance perhaps are the results of the other two experiments. In experiment 1, when the patient received the approximate equivalent of the neutral fat given in experiment 2, in the form of the products of hydrolysis, no dye whatsoever reached the pleural cavity during the subsequent 48 hours, although chyle was accumulating there as usual. In experiment 3 a smaller dose of fatty acid was given. On this occasion a small quantity of Sudan III, considerably less than in experiment 2, was recovered from the chylothorax, but it arrived there later, somewhere between $6^{1}/_{3}$ and 24 hours after the ingestion of the stained fatty acid, whereas there was visible staining at 3 hours, and heavy staining at 5 hours in the experiment with neutral fat. Probably the neutral fat which the patient unfortunately ate for his tea 8 hours after the ingestion of the stained oleic acid dissolved some dye from the heavily stained oleic acid still remaining in the intestine, Sudan III being soluble in both types of fat. This would explain the presence of a small quantity of Sudan III in the effusion next morning, and the discrepancy between the first and the third experiments.

These findings could be criticised on the grounds that the leakage of chyle through the fistula may have been intermittent. However, during the 36 days' observation in hospital until the sudden change in type of effusion, aspirations were done on 18, and throughout this period the recovery remained constant at about 600 ml a day. On no occasion was there a failure to obtain a substantial volume of fluid, such as might have been expected had the fistula been leaking intermittently.

If, as has for so long been generally accepted, complete hydrolysis were an essential preliminary to the absorption of any fat, one would expect about the same degree of staining of the chylous effusion to follow the ingestion of split as of unsplit fat. But the well-marked difference in staining of the chyle in the present experiments is in agreement with Frazer's work on feeding sudanised fats to rats, and supports his theory that the two kinds of fat are treated differently in the intestine and absorbed by different routes—the fatty acids via the portal circulation, and the neutral fat via the lymphatics.

ulcerative or inflammatory effects of gastric juice Pfeiffer (1939) has shown that the diarrhœa in gastro jejunocolic fistula is due not to "gastric" irritation but to a small bowel enteritis from the passage of fæcal material into the jejunum

Lastly, the pH of the colon is mildly to the acid side (6 5), suggesting that it might be more resistant than the jejunum

There is very little experimental evidence of the effect of gastric juice on the colon, but what there is suggests that it is not unduly susceptible In 1900 Reerink (Ivy et al 1950) found that patch implants of the colon into the stomachs of dogs did not ulcerate Dragstedt and Vaughan (1924) took a loop of a dog's colon (12 cm long) with its blood supply intact, and opened it out as a flap The flap was sewn into a large window in the stomach 1 in. from the pylorus. At the end of a year the colon was entirely normal macroscopically and microscopically

MUCUS PROTECTION THEORY

One theory of the cause of peptic ulceration is that of diminished protection by mucus Florey and Harding (1934) suggested as a result of experiments in five different species of animals that malfunctioning of Brunner's glands, which secrete mucus profusely in the duodenum, may be responsible for duodenal ulcer They showed, too, that the duodenum is the most resistant portion of the small intestine because of the mucous secretion of Brunner's glands The vagus is the secretory nerve to Brunner's glands as well as to the stomach, but nervous secretion is, of course, only one phase in their secretory activities

Florey et al (1941) state that the colonic mucosa can maintain a layer of mucus on its surface and can vary its thickness by secretion or reabsorption according to the needs of the moment The alkali content of colonic secretion is considerable, and probably has the function of neutralising acids produced by bacterial action Wright et al. (1938) have shown that the interior of fæcal masses from the cat's colon has a pH as low as 4 8, but at the surface the pH is 7

Ivy et al. (1950), summarising the evidence of the protective action of mucus in the prevention of auto digestion of the stomach, state

> ' the difference in resistance of the epithelium of the stomach to HCl pepsin is undoubtedly chiefly due to the continuous layer of mucus secreting epithelium possessed by the stomach and not by the duodenum and jejunum The greater resistance of the duodenum compared to the jejunum is due to the scarcity of mucous glands in the latter '

OPERATIVE PROCEDURE

The following anatomical and physiological findings are relevant to the operation described below

1 The pylorus admits the tip of the little finger, but beyond the pylorus the duodenum is the widest portion

TABLE I—RECORDS OF 20 CASES OF GASTRIC RECONSTRUCTION FOR PEPTIC ULCERATION

Case no	Sex and age	Duration of symptoms (years)	Previous medical treatment	Complications of ulcer	Lesion at operation	Remarks
1	M 40	4	3 years	Nil	G U	Healed tuberculosis chest right nephrectomy for tuberc. 4 years ago Gained 1 st. in 2 mths very well and gaining weight 3 mths later
2	M 49	10	Never strict	Nil	Anterior and posterior D U	5 lb above preop weight at 3 mths
3	M 63	4	Some	Nil	Two ulcers on lesser curvature	Preop weight gained at 3 mths
4	F 51	20	Strict 2 years	Nil	Chronic posterior D U penetrating pancreas	Long loop Stomach slow at first but much better at 2 mths Gaining weight rapidly at 3 mths
5	M 54	8–10			Posterior D U penetrating pancreas	
6	M 45	15	10 years	Perforation 9 years ago admitted with hæmatemesis	Chronic D U pyloric stenosis	Long loop Enormous appetite rapid gain in weight
7	M 37	10	10 years	Ulcer leak	G U	Rapid gain in weight
8	M 40	22	For years		Anterior and posterior D U penetrating pancreas	
9	F 66	2	2 years	Hæmatemesis	G U	
10	M 52	30	Several years	Nil	Anterior D U penetrating liver	
11	M 24	13	5 years	Nil	Chronic D U	Orphan living in lodgings. Gross loss of weight preoperatively
12	M 50	30	9 years since gastrojejunostomy	Jejunal ulcer	Large jejunal ulcer D U	
13	M 34	7	5 years		Chronic D U and G U	
14	M 48	2	Some months	Nil	Anterior and posterior D U	
15	F 64	2	Nil	Hæmatemesis	Anterior D U and posterior G U	Admitted with hæmatemesis
16	F 60	4	4 years	Hæmatemesis and melæna 2 years ago		Admitted with severe hæmatemesis
17	M 29	6	4 years	Perforation 3 years ago followed by subphrenic abscess	Anterior D U penetrating liver posterior D U penetrating pancreas pyloric stenosis	Gunshot wound of liver 1943 F B still present Only single layer of sutures possible at coloduodenal anastomosis posteriorly Gaining weight condition excellent 6 weeks later
18	M 45	10–15	10 years	Perforated while under medical treatment immediately preoperatively	Prepyloric ulcer and D U penetrating pancreas	
19	M 39	6	Never kept to diet	Ulcer leak	Posterior D U	
20	M 52	11	4 years diet	Perforation 4 years ago	Large prepyloric ulcer	

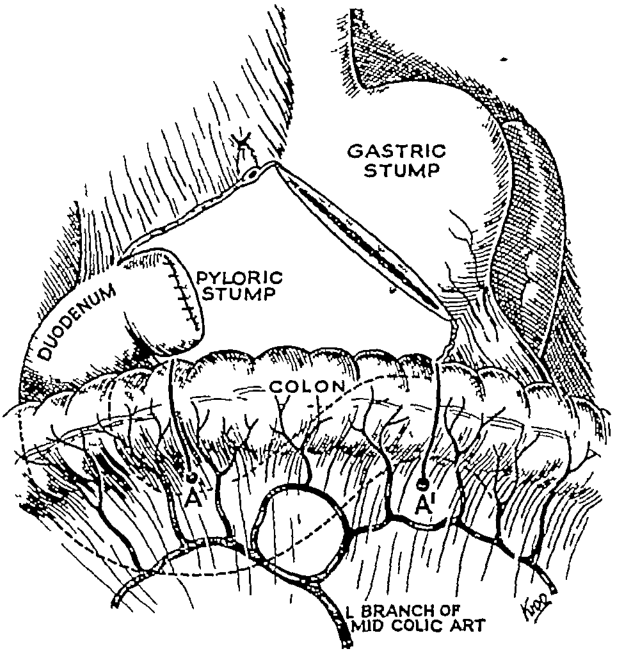

Fig 1—Extent of gastric resection The pylorus is removed separately after insertion of the posterior seromuscular coloduodenal suture A, A^{1}: sites of division of colon and transverse mesocolon

the small intestine to acid chyme, and that this is highest in the duodenum and lowest in the terminal ileum The upper jejunum is chosen as the point of anastomosis, not because it is the most resistant but because gastroduodenal anastomosis is usually not possible without (*a*) limiting the amount of stomach resected, (*b*) difficult and dangerous mobilisation of the duodenum

2 Masticated food untreated and unmixed with pancreatic juice, bile, and high intestinal juice, is passed directly into the second foot of the jejunum Rapid emptying of the small intestine is common after gastrectomy Iron is absorbed in the duodenum and higher jejunum, so it is not surprising that microcytic anæmia is not uncommon, particularly as rapid emptying of the stomach is almost the rule

3 Fatal leakage of the blind duodenal stump may occur in the immediate postoperative period if there is distension of the duodenum from obstruction at the anastomosis The most experienced gastrectomists confess to this mishap as an occasional cause of fatality

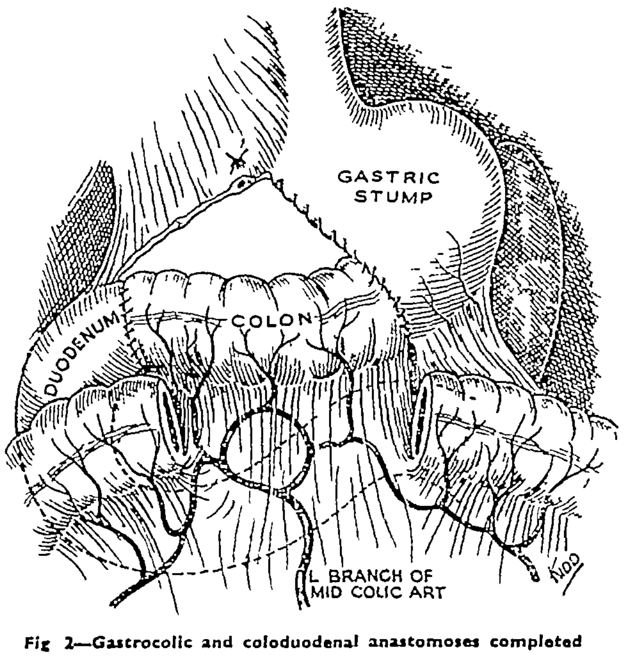

Fig 2—Gastrocolic and coloduodenal anastomoses completed

The perfect operation is one which reduces acidity sufficiently to prevent recurrent or stomal ulceration, and interferes little or not at all with the functions of the stomach and duodenum Subtotal gastrectomy satisfies the first of these criteria but ignores the latter

PROPERTIES OF COLONIC MUCOSA

For some years I have been interested in finding a method by which the acid reducing effect of subtotal gastrectomy could be achieved without unduly reducing the stomach's capacity, while retaining the normal process of the stomach emptying by the duodenum This is technically possible in some degree at least, if the colon is as resistant to gastric juice as I have reason to believe it is If it is only as resistant as the jejunum, the operation would still be justifiable having regard to other considerations

Nearly five years have passed since I operated on a man with a gastrojejunocolic fistula, too ill to be treated by any method but division of the transverse colon on either side of the fistula and invagination of the colonic ends into the stomach The continuity of the colon was restored by end to end suture (Moroney 1948)

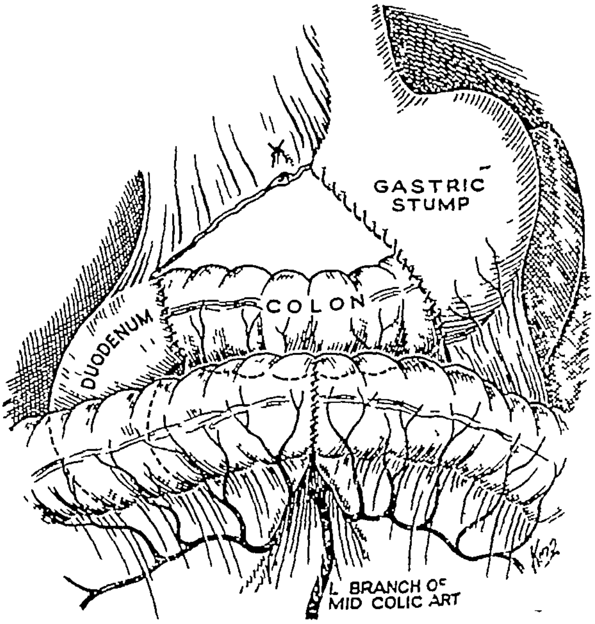

Fig 3—Operation completed

This patient has since remained well, and the two colonic loops in his stomach have not ulcerated, although they have been exposed to a juice which had "caused" a duodenal ulcer, and subsequently a jejunal ulcer sufficiently severe to perforate the colon The jejunal ulcer, too, has healed, and the original duodenal ulcer has not been reactivated It would appear that the colonic implants have had a beneficial effect, probably because of their profuse mucous secretion, which is an excellent buffer of acid

Wilkie (1934) first practised colonic exclusion in a case of gastrocolic fistula from a gastric ulcer At a second operation eleven weeks later he noted that the colonic loops in the stomach were practically empty and pale, they certainly were not inflamed or ulcerated. The only other case similar to my own was described by Eggers (1939) His patient remained quite well for some years, but had a recurrence at the site of his original lesion in the duodenum with acute perforation, later carcinoma of the ascending colon was successfully resected, and there were no further ulcer symptoms

I have previously observed—and have since confirmed this in 2 cases of gastrojejunocolic fistula—that the colonic mucosa in these patients is singularly free from ulcerative or inflammatory effects of gastric juice Pfeiffer (1939) has shown that the diarrhœa in gastro jejunocolic fistula is due not to "gastric" irritation but to a small bowel enteritis from the passage of fæcal material into the jejunum

Lastly, the pH of the colon is mildly to the acid side (6 5), suggesting that it might be more resistant than the jejunum

There is very little experimental evidence of the effect of gastric juice on the colon, but what there is suggests that it is not unduly susceptible In 1900 Reerink (Ivy et al 1950) found that patch implants of the colon into the stomachs of dogs did not ulcerate Dragstedt and Vaughan (1924) took a loop of a dog's colon (12 cm long) with its blood supply intact, and opened it out as a flap The flap was sewn into a large window in the stomach 1 in. from the pylorus At the end of a year the colon was entirely normal macroscopically and microscopically

THE NATURE OF AUTO-AGGLUTININS

G W G Bird
M.B Madras
LIEUT COLONEL, ARMY MEDICAL CORPS, OFFICER IN CHARGE, BLOOD TRANSFUSION DEPARTMENT, ARMED FORCES MEDICAL COLLEGE, POONA, INDIA

SERUM obtained from a woman with acquired hæmolytic anæmia of unknown ætiology, and belonging to group AB (as determined by testing fresh cells thoroughly washed with isotonic saline solution at 56°C) contained non specific "cold" agglutinins (Landsteiner and Levine 1926) active at room temperature against groups O, A, and B, and the patient's own cells

The patient had never been transfused but had been pregnant twice Her first child had died at the age of 5 days, no intelligent description of its illness could be obtained The second child (group AB) is now aged 9 months and has always been in good health The patient's husband is group B No Rh antibodies were present in her serum

The non specific agglutinins were completely absorbed by the patient's own cells and ceased to agglutinate O, A, and B cells as well

Another sample of the patient's serum was absorbed with O cells till they were no longer agglutinated Activity against A, B, and the patient's own cells persisted The serum was next absorbed with A cells till they were no longer agglutinated Activity against B and the patient's own cells persisted, Finally, the serum was absorbed with B cells till they were no longer agglutinated The activity against the patient's own cells persisted, though the reaction was weak

The "non specific" agglutinins present in the serum seem to be a combination of agglutinins consisting of anti O, anti A, anti B, and anti own cell components The patient's cell antigens therefore seem to consist of A, B (the patient was group AB), O, and at least a fourth component This would explain why all agglutinin components were absorbed by the patient's cells but were removed specifically by O, A, and B cells

The titre and thermal amplitude of the various antibody components detected are shown in the accompanying table

Antibody component	Titre at 4 C	Highest temperature at which active (up to 37 C)
Anti O	128	37 C
Anti A	128	37 C
Anti B	16	30 C
Anti-own cell	8	30 C

It was found that A and B group specific substance could also absorb the anti A and anti B components respectively

Attempts to split off the absorbed agglutinins by the method of Landsteiner, as described by Schiff and Boyd (1942), were unsuccessful However, Schiff and Boyd state that failure is common and should not be considered a contradiction of a successful absorption experiment

Owing to the lack of a sufficiently large panel of typed cells it was impossible to determine whether the anti O component of the serum was true anti O or the anti H of Morgan and Watkins (1948), or to identify the antibody remaining after absorption with O A, and B cells

Seven sera of group AB containing auto agglutinins acting only in the cold were examined Absorptions were done in the cold, and the separation of serum effected with a refrigerated centrifuge In all seven sera anti O, anti A and anti B components were detected, though the anti own cell component was not demonstrable

DISCUSSION

The suggestion of Dockeray and Sachs (1941) that in anti O agglutinin present in certain sera may be responsible for auto agglutination seems to be correct, though not wholly so

Stratton (1943) could attribute auto agglutination to anti O activity in three cases but not in two others in one of the latter all cells were agglutinated with almost equal intensity, whereas the other showed slightly greater activity against O cells Multiple specific anti bodies may explain his findings

Possibly the non specific and specific cold agglutinins encountered together in two sera by Boorman et al (1946) and in a case previously examined by me represent incompletely investigated examples of similar cases

The thermal amplitude of an auto agglutinin in respect of O cells, "compatible" A or B cells from the iso-agglutinin point of view, and the individual's own cells, has been observed often to be different in each case Multiple specific antibodies would explain this fact The suggestion of Bialosuknia and Hirszfeld (1923), that different cold agglutinins come into action, at different temperatures, seems to be justified However, these workers have not defined the exact nature of these agglutinins

Auto agglutinins belong to the γ globulin fraction of the serum (Stats et al 1943), a different fraction from that to which the iso agglutinins belong (Cohn 1947) They are probably of immune origin, their production being stimulated by the broken down stromata of red cells, or by various diseases—e g, virus pneumonia

The fact that auto agglutinins may have specific action against ABO antigens is possibly definite proof that there are two types of ABO antibodies Two types of Rh antibodies are known to exist (Wiener 1948), but the possible presence of two kinds of ABO antibodies has so far only been inferred or demonstrated indirectly (Wiener et al 1949)

I am grateful to Dr A E Mourant for his perusal of the original draft and for many helpful suggestions, to Mr K K Gopal Pillai for technical assistance, to the National Chemical Laboratory, Poona, for use of their refrigerated centrifuge, and to the Director General, Armed Forces Medical Services, India, for permission to publish

PADDINGTON GREEN CHILDREN'S HOSPITAL, LONDON

BACILLÆMIA due to *Shigella shigæ* or to *Sh flexneri* is well recognised though rare, but we have been unable to find any record of bacillæmia due to *Sh sonnei* since 1914, when this organism was first isolated

Felsen (1945) reviewing published reports from 1900, found 34 cases of bacillæmia in Shigella infections, but not one of them was due to *Sh sonnei*

High fever is unusual in Sonne dysentery, and the clinical state of the patient seldom indicates any need for of the small intestine The diameter is in most cases equal to that of the transverse colon

2 Movements in the transverse colon are almost negligible apart from "mass movement," so that if it is utilised in a way that seems to be anatomically antiperistaltic this is not a serious matter, within limits, and this is proved by satisfactory emptying in my cases

3 That the colon is very distensible is well known, but so is the duodenum I operated on a man three years ago who had had a peculiarly low gastrectomy performed two months earlier, the duodenum was closed and an anastomosis with a very long loop to the jejunum had been made Three hours after a high intestinal obstruction from volvulus of the stomal loops, he had a mass in the right hypochondrium almost the size of a fœtal head, and this, I confirmed at operation, was the distended duodenum

4 A free loop of transverse colon can be cut without endangering its blood supply

A preliminary course of medical treatment makes resection easier and safer The colon is treated with succinylsulphathiazole, and the final colonic washout two hours before operation ensures an empty colon A slow blood transfusion, begun at the start of the operation, prevents shock, and the patient returns to bed with a pulse of good volume and a rate of about 80–90 per min A Ryle's tube is passed preoperatively

A midline incision is usually satisfactory, but for reconstruction of a previous gastrectomy a double Kocher is the incision of choice The stomach and pylorus are widely resected with excision of the ulcer The insertion of the posterior coloduodenal seromuscular suture is easier if the stomach is divided to the left of the pylorus and closed as shown in fig 1 After the insertion of this suture the pylorus and pyloric antrum are resected A free loop of transverse colon with its blood supply intact is taken One end is sutured to the duodenum with two layers of catgut, the other to the gastric stump (fig 2) The optimum amount of colon to use, and the best method of anastomosis to the gastric stump, are still uncertain; in end to end anastomosis I have used between $2^1/_2$ in and 5 in In 4 cases a lateral anastomosis of the colon to the stomach was made and 7 in was used

The colonic continuity is restored by end to end anastomosis (fig 3), and in the majority of cases no clamps are used on the colon or duodenum It is usually unnecessary to tie any vessels in the transverse mesocolon The abdomen is closed with a small corrugated rubber drain in the right hypochondrium, and 1 g of streptomycin is injected down the Ryle's tube before the patient returns to bed

Penicillin and streptomycin parenterally are begun on the day of operation and continued for five days In only 3 out of 22 cases was the wound infected, and the infection was slight

In all cases there is still the opportunity of excising the loop and performing a gastrojejunal anastomosis, or of making a short circuit from the "stomach mechanism" to the jejunum, should time show this to be necessary or desirable

The records of 20 cases submitted to this operation are summarised in table I A further 2 cases were operated on by this technique because of post gastrectomy bilious vomiting

Case 21 —Woman aged 48 Indigestion, 30 years Subtotal gastrectomy for gastric ulcer 18 months ago, followed almost at once by bilious vomiting and loss of weight, 6 months later jejunal loops reversed with no improvement Weight loss in 18 months, 3 st Bilious vomiting, eating only bread and butter Persistent hypochromic anæmia

Colonic restoration of stomach At 6 weeks able to eat anything for the first time in 30 years Gaining weight No vomiting

Case 22 —Woman, aged 61 Perforation 4 years ago Gastrectomy for duodenal ulcer 1 year ago, jaundice 6 months later Weight loss in 1 year, 3 st Bilious vomiting

Colonic restoration of stomach, gall bladder normal Very comfortable at 1 month Able to eat anything Gaining weight No vomiting

Data on the 3 cases in which gastric reconstruction was not undertaken are given in table II

TABLE II—DATA ON CASES IN WHICH GASTRIC RECONSTRUCTION WAS NOT UNDERTAKEN

Case no	Age (yr)	Lesion	Contra indication	Operation
1	52	Duodenal ulcer	Diverticulitis of pelvic colon	Gastrectomy with gastrojejunal anastomosis
2	17	Acute hæmatemesis, gastric ulcer	Colon not prepared	As in case 1
3	65	Pyloric stenosis cholelithiasis, myocarditis	Unnecessary	Gastrojejunostomy cholecystectomy

All patients have had radiological examination with barium meals a month after operation, and some at three months In the majority the "stomach mechanism" empties in 1–5 hours, though with longer loops emptying is slower, in some emptying is more rapid, but at three months the rate seems to be settling down to about $2^1/_2$–4 hours The anastomoses are completely healed, and the mucosal pattern of the small intestine is "feathery", emptying of the small bowel is not unduly quick In 4 cases I have seen the colonic loop fill with barium, the loop contract with refilling of the stomach, and at the same time a trickle down the duodenum This suggests that some maceration of food takes place as in the normal stomach

Fractional test meal (more likely to be of value in this type of anastomosis than others) shows complete achlorhydria, or very little acid, and excess of mucus The glucose tolerance curves are normal, and there is no evidence of steatorrhœa

Clinically all patients have had complete relief of symptoms, and can eat larger meals than those who have had subtotal gastrectomy The gain in weight has been steady The earliest case is only in the fifth postoperative month

CONCLUSION

This procedure is surgically a little more extensive, but physiologically much less destructive, than subtotal gastrectomy It shows early promise that the function of the normal stomach may be largely preserved with consequently little or no interference with the function of the small intestine At this early stage the value of this function cannot be assessed

SUMMARY

After gastric resection there are advantages in restoring the food canal in continuity, and in providing a "stomach storage" mechanism

A method of achieving this in man, using a free loop of transverse colon, is described The colon is comparatively resistant to gastric juice

Of 22 patients submitted to this operation all have survived 20 were operated on because of peptic ulcer, and 2 because of post gastrectomy bilious vomiting

The longest postoperative follow up is 5 months Longer observation and further research are necessary for the evaluation of this technique

THE NATURE OF AUTO-AGGLUTININS

G W G Bird
M.B Madras
LIEUT COLONEL, ARMY MEDICAL CORPS, OFFICER IN CHARGE, BLOOD TRANSFUSION DEPARTMENT, ARMED FORCES MEDICAL COLLEGE, POONA, INDIA

Serum obtained from a woman with acquired hæmolytic anæmia of unknown ætiology, and belonging to group AB (as determined by testing fresh cells thoroughly washed with isotonic saline solution at 56°C) contained non specific "cold" agglutinins (Landsteiner and Levine 1926) active at room temperature against groups O, A, and B, and the patient's own cells

The patient had never been transfused but had been pregnant twice Her first child had died at the age of 5 days, no intelligent description of its illness could be obtained The second child (group AB) is now aged 9 months and has always been in good health The patient's husband is group B No Rh antibodies were present in her serum

The non specific agglutinins were completely absorbed by the patient's own cells and ceased to agglutinate O, A, and B cells as well

Another sample of the patient's serum was absorbed with O cells till they were no longer agglutinated Activity against A, B, and the patient's own cells persisted The serum was next absorbed with A cells till they were no longer agglutinated Activity against B and the patient's own cells persisted, Finally, the serum was absorbed with B cells till they were no longer agglutinated The activity against the patient's own cells persisted, though the reaction was weak

The "non specific" agglutinins present in the serum seem to be a combination of agglutinins consisting of anti O, anti A, anti-B, and anti own cell components The patient's cell antigens therefore seem to consist of A, B (the patient was group AB), O, and at least a fourth component This would explain why all agglutinin components were absorbed by the patient's cells but were removed specifically by O, A, and B cells

The titre and thermal amplitude of the various antibody components detected are shown in the accompanying table

Antibody component	Titre at 4 C	Highest temperature at which active (up to 37 C)
Anti O	128	37 C
Anti A	128	37 C
Anti B	16	30°C
Anti-own cell	8	30°C

It was found that A and B group specific substance could also absorb the anti A and anti B components respectively

Attempts to split off the absorbed agglutinins by the method of Landsteiner, as described by Schiff and Boyd (1942), were unsuccessful However, Schiff and Boyd state that failure is common and should not be considered a contradiction of a successful absorption experiment

Owing to the lack of a sufficiently large panel of typed cells it was impossible to determine whether the anti O component of the serum was true anti O or the anti H of Morgan and Watkins (1948), or to identify the antibody remaining after absorption with O, A, and B cells

Seven sera of group AB containing auto agglutinins acting only in the cold were examined Absorptions were done in the cold, and the separation of serum effected with a refrigerated centrifuge In all seven sera anti O, anti A and anti B components were detected, though the anti own cell component was not demonstrable

DISCUSSION

The suggestion of Dockeray and Sachs (1941) that an anti O agglutinin present in certain sera may be responsible for auto agglutination seems to be correct, though not wholly so

Stratton (1943) could attribute auto-agglutination to anti O activity in three cases but not in two others in one of the latter all cells were agglutinated with almost equal intensity, whereas the other showed slightly greater activity against O cells Multiple specific antibodies may explain his findings

Possibly the non specific and specific cold agglutinins encountered together in two sera by Boorman et al (1946) and in a case previously examined by me represent incompletely investigated examples of similar cases

The thermal amplitude of an auto agglutinin in respect of O cells, "compatible" A or B cells from the iso agglutinin point of view, and the individual's own cells, has been observed often to be different in each case Multiple specific antibodies would explain this fact The suggestion of Bialosuknia and Hirszfeld (1923), that different cold agglutinins come into action, at different temperatures, seems to be justified However, these workers have not defined the exact nature of these agglutinins

Auto agglutinins belong to the γ globulin fraction of the serum (Stats et al 1943), a different fraction from that to which the iso agglutinins belong (Cohn 1947) They are probably of immune origin, their production being stimulated by the broken down stromata of red cells, or by various diseases—e g, virus pneumonia

The fact that auto agglutinins may have specific action against ABO antigens is possibly definite proof that there are two types of ABO antibodies Two types of Rh antibodies are known to exist (Wiener 1948), but the possible presence of two kinds of ABO antibodies has so far only been inferred or demonstrated indirectly (Wiener et al 1949)

I am grateful to Dr A E Mourant for his perusal of the original draft and for many helpful suggestions, to Mr K K Gopal Pillai for technical assistance, to the National Chemical Laboratory, Poona, for use of their refrigerated centrifuge, and to the Director General, Armed Forces Medical Services, India, for permission to publish.

PATHOLOGIST

PADDINGTON GREEN CHILDREN'S HOSPITAL, LONDON

Bacillæmia due to *Shigella shigæ* or to *Sh flexneri* is well recognised though rare, but we have been unable to find any record of bacillæmia due to *Sh sonnei* since 1914, when this organism was first isolated

Felsen (1945), reviewing published reports from 1900, found 34 cases of bacillæmia in Shigella infections, but not one of them was due to *Sh sonnei*

High fever is unusual in Sonne dysentery, and the clinical state of the patient seldom indicates any need for blood culture in diagnosis We have made blood cultures from seven children with Sonne dysentery and have had one positive result In four of these cases the temperature was 102–104°F

CASE RECORD

A boy aged 2 years, was admitted on Dec 17, 1950 Unwell during that morning, he had had a rigor in the afternoon and passed four unformed yellow stools He was then admitted to hospital and shortly after passed an unformed stool, lost consciousness, and became cyanosed, rallying after a short interval His temperature was 104°F and pulse rate 140 He was not obviously dehydrated A subcuticular whitlow was present on the right index finger There were no other abnormal findings Septicæmia was provisionally diagnosed and a blood culture made During the next twenty four hours the boy passed seven stools, each containing blood and mucopus Thereafter he had one bowel movement daily His temperature fell to normal next day, and his general condition improved gradually No other member of the family of six was similarly ill

Treatment —The patient was given phthalyl sulphathiazole followed by chloramphenicol The stools remained positive for *Sh sonnei* Succinyl sulphathiazole was then given, after which a negative rectal swab was obtained

Investigations —A non motile gram negative organism was isolated from the blood, fæces, and urine This organism produced acid without gas in glucose and mannite with weak acidity in lactose and saccharose after forty eight hours No indole was produced Saline suspensions of living and of heat killed organisms from each of the three sources were agglutinated in a few hours at 55°C to a titre of 1 250 by standard *Sh sonnei* antiserum The patient's serum, a week after onset of the illness, agglutinated suspensions of standard *Sh sonnei* and his own strain of the organism to titres of 1 250 and 1 200 respectively Two successive periods of an hour's incubation at 37°C of mixed standard *Sh sonnei* suspension (concentrated) and the patient's serum removed the agglutinins from the latter for the patient's organism Reciprocal absorption (patient's organism with standard antiserum) removed the agglutinins against the standard suspension

There can be little doubt that infection with *Sh sonnei* produced in this child an unusually severe though brief illness due to invasion of the blood by the organism at the onset

We are grateful to Mr E McHenry for technical assistance

Medical Societies

RENAL ASSOCIATION

THIS association met in London on April 26, under the chairmanship of Dr A A OSMAN

KIDNEY AND CIRCULATORY SYSTEM

Prof K J **FRANKLIN** suggested that, although he was confining his remarks to the blood circulatory system, the large size of the renal lymphatics should stimulate research workers to investigate more fully the physiological significance of these structures He pointed out that the circulatory system and kidney function are closely inter related The kidney requires a sufficient and normally distributed blood supply in order to function efficiently, while the circulatory system is profoundly influenced by renin and "vaso excitor material" (V E M), which are produced by ischæmic renal cortical tissue We are ignorant, he said, of the possible effects of the modern so called "hypotensive anæsthesia" on renal function during and after operation

Turning to the influence of nervous impulses on the kidney, Professor Franklin said that until the work carried out at the Nuffield Institute for Medical Research during the period 1945–47 there was no indication that nervous impulses reaching the kidney did other than produce a generalised vasoconstriction throughout the kidney, although the morbid anatomical findings in symmetrical renal cortical necrosis, and Claude Bernard's mention of arterial streamlines in the renal veins, might have given an earlier clue to the true state of affairs

Direct visual observation of events within the mammalian kidney is not possible Hence indirect methods must be used The inherent limitations of such techniques must be realised, and a rigorous appraisal made of the effect of operative procedures and of the validity of assumptions and mathematical calculations Renal vasoconstriction in response to acute hypoxia is nervously mediated, and in Professor Franklin's view the interlobular arteries and their offshoots can constrict completely in response to stimulation which results in only partial occlusion of the main renal artery Cineradiographic, radiological, and histological evidence supports the view that renal ischæmia involves the progressive occlusion of the interlobular arteries and their glomerular branches The evidence suggests that this vasoconstriction affects the most peripherally situated vessels first and spreads through the renal cortex centrically, from without inwards, as far as the basal glomeruli During renal cortical ischæmia blood is diverted through the juxtamedullary (or "basal") glomeruli and the vasa recta system Whether the medulla is congested or not depends on the balance between reduction in total renal inflow and reduction in cortical flow, and perhaps also on renal venous constriction

Professor Franklin held that such terms as "greater circulation" and "lesser circulation" in connection with the renal vascular system are best avoided He strongly deprecated the use of the terms "renal shunt" and "Oxford shunt" unless these are precisely defined

In conclusion, he reviewed some experimental and clinical evidence suggesting that a diversion of blood from the renal cortex, similar to that observed experimentally, takes place in man under certain conditions—with exercise or dioxan poisoning, and as the ætiological factor in the symmetrical renal cortical necrosis associated with concealed accidental hæmorrhage

RENAL CHANGES IN OBSTETRIC SHOCK

Dr A **TELFORD GOVAN**, who discussed renal changes in obstetric shock, divided his cases into four groups (1) non toxæmic cases with shock caused by such conditions as postpartum hæmorrhage, placenta prævia, or uterine rupture, (2) toxæmic cases, mostly with accidental hæmorrhage, (3) 10 cases of symmetrical cortical necrosis, and (4) 10 cases of "lower nephron nephrosis" From a study of the renal pathology in 120 fatal cases in the first group, he has found that where death takes place within the first two hours both cortex and medulla are pale and the vessels spastic, between two and three hours there is relative congestion of the medulla and deep glomeruli, and the cortical veins are full of blood, thereafter the cortical vessels appear to reopen patchily, polymorphs are numerous, and intertubular œdema sometimes develops In 1 case with well marked necrosis of the proximal convoluted tubule posterior pituitary extract was given repeatedly during the stage of shock

In the second group the early renal changes are identical, but all stages are prolonged After about ten hours vascular dilatation occurs, and this persists for up to forty hours The cortex is swollen and the glomeruli grossly congested, their capsules being ballooned out by plasma Some glomerular degeneration may take place After twenty four hours tubular necrosis is well marked, blood or hæmoglobin casts are common, and thrombi are found in the small arteries and glomeruli These changes indicate that damage may be caused by the vascular dilatation as well as the preceding spasm

With "lower nephron nephrosis" the early changes are similar After four days casts may be found in almost every tubule, but their number then diminishes, and the tubules show evidence of rapid repair Ballooning of the glomerular capsule is pronounced, and there are varying degrees of glomerular thrombosis and damage These lesions differ only in degree from those found in cortical necrosis, and Dr Govan feels that both syndromes have the same ætiology In addition, the earlier phases of both "lower nephron nephrosis" and symmetrical cortical necrosis can be seen in toxæmic cases of shock

Dr IAN MACGILLIVRAY spoke on the clinical aspects of renal dysfunction in obstetric shock In all cases of shock there is an immediate rise of blood urea Where this is not great there is usually only transient renal dysfunction, but the group in which there is a greater rise and a persistently low urine urea are almost all cases with a combination of concealed accidental hæmorrhage and toxæmia, and the shock lasts longer and oliguria persists even after recovery from the shocked state. Oliguria of more than three days' duration is of grave prognosis

Dr MacGillivray went on to discuss the clinical aspects of Dr Govan's cases of "lower nephron nephrosis" and cortical necrosis He suggested that the stimuli conducive to renal cortical necrosis in pregnancy are pre eclamptic toxæmia or sepsis, associated with shock The same factors occurred in the cases of "lower nephron nephrosis", but toxæmia alone can induce this condition, and those cases in which toxæmia and shock were present did not have both factors to a severe extent Of 4 non toxæmic cases with "lower nephron nephrosis," 3 had sepsis and shock, and the 4th had had an intra uterine injection of posterior-pituitary extract while in the shocked state All the cases of cortical necrosis had a well marked rise of temperature on the second or third day, unassociated with sepsis This fever was not present in the "lower nephron nephrosis' cases, except for 1 in which some degree of thrombosis of the renal cortical arterioles was found post mortem Dr MacGillivray suggested that the rise of temperature may be associated with massive thrombosis in the renal cortex He did not think hæmaturia reliable as a diagnostic criterion of cortical necrosis, because this was present also in his cases of "lower nephron nephrosis" He advised four hourly temperature charting, since the fever of cortical necrosis may be transient

Any shocked patient, especially with associated pre eclampsia, may develop a severe renal lesion and the blood urea is a better prognostic guide than the amount of urine passed Fatal renal lesions may be avoided by preventing shock, or treating it early, and oliguria persisting for more than three days is probably best treated with limitation of fluids and a protein free diet

SPINAL ANÆSTHESIA AND THE KIDNEY

Dr A H GALLEY recalled that chloroform lowers the systemic blood pressure and reduces the glomerular filtration rate, and that ether stimulates the neuro hypophysis Soda lime, as used in closed circuit anæsthesia, is not a completely efficient carbon dioxide absorbent In the presence of reduced pulmonary ventilation during closed circuit anæsthesia, enough carbon dioxide might accumulate to cause diversion of blood from the periphery of the renal cortex This danger can be overcome by intermittently squeezing the anæsthetic bag

In view of some recent work by Professor Franklin and his colleagues Dr Galley felt that spinal anæsthesia might influence renal function by abolishing the effects of stimulation of the chemoreceptor centres in the spinal cord which are responsible for the renal circulatory responses to hypoxia and hypercapnia In addition, the hypotension and hypoventilation which result from spinal anæsthesia are disadvantageous from the point of view of their possibly adverse effects on renal function

Therapeutically, spinal analgesia is a supplementary measure in the treatment of a number of conditions, including hypertensive encephalopathy in pregnancy Dr Galley concluded with a plea for its application as soon as possible after the decision has been made to enlist the help of the anæsthetist

Reviews of Books

Insects and Hygiene

JAMES R BUSVINE, PH.D, D SC, Department of Entomology, London School of Hygiene and Tropical Medicine London Methuen 1951 Pp 482 30s

INSECTS do not play the overwhelming part in public health in this country which they do in tropical lands, nor is the visible destruction in the home as spectacular as that achieved by termites, for instance, in warmer climates But the fact remains that we have a very large number of insect pests of greater or less importance to medicine, commerce, and domestic life At one time or another they force themselves upon the notice of the medical officer of health, the sanitary inspector, and every applied entomologist who has to do with warehouses or private homes or the many trade processes vulnerable to insects Dr Busvine sets out to provide a complete compendium of the information required to cope with these pests, starting with a straightforward account of the structure and classification of insects, their anatomy and physiology, and the general principles of their ecology Chapters follow dealing with the general principles of insect control and its organisation, and the theory and uses of insecticides The insects themselves are dealt with on a practical ecological basis house-flies and blowflies, the blood-sucking flies, the arthropod parasites of the human body, pests of foodstuffs, refuse and sewage, clothes moths and carpet beetles, wood-boring beetles, stinging and biting insects, and various nuisances Technical appendices include keys to most of the insects, and information about the more important insecticides, and references and a good index complete a book that is both comprehensive and practical

James Lind Founder of Nautical Medicine

LOUIS H RODDIS, captain, Medical Corps, U S Navy New York. Henry Schuman. 1950 Pp 177 $3

THE reading of biographies of certain naval heroes —admirals all—tends to become a weariness of the flesh It is a pleasant change, therefore, to turn to the biography of a naval surgeon and to find there a better balanced picture of old-time sea life, where battles were only occasional and sickness unfortunately occurred every day of the week The battle against disease at sea in the 18th century was particularly hard, and since people are always ready to read of a good fight, Captain Roddis has told again the story of James Lind, M D, of Edinburgh, who took such a prominent part in it

Lind went to sea in 1739, remaining there until 1748 when he returned to Edinburgh In 1753 he published his *Treatise on the Scurvy* and four years afterwards *An Essay on Preserving the Health of Seamen in the Royal Navy* These two books helped him to the appointment of physician in charge of the new Royal Naval Hospital Haslar in 1758 Here he wrote his third book, *Essay on Diseases Incidental to Europeans in Hot Climates* His *Treatise on the Scurvy* added to the long record of the experiences of seamen and earlier surgeons a note of his experiments in the *Salisbury* 50 guns in 1745, which led him to conclude that lemon or orange juice was a rapid, sure and simple cure for the disease and a preventive Captain Cook, as we all know put Lind's ideas into practice with splendid results

It is perhaps worth noting that though Henry VIII did much for the Navy, he did not build its first ship in 1488 (his acces sion was in 1509), and that though Charles I built some fine ships, he was absent minded about their crews more than half starved, they mostly died of scurvy The book is a graceful tribute by a naval surgeon of today to a naval surgeon of long ago who was always honest both with himself and others

The Order of the Court

J DUDLEY PANK London Hodder & Stoughton 1951 Pp 191 8s 6d

Mr Pank has a long experience of approved schools, and his thesis is that the delinquent boys in such schools "could be the salt of the earth if the iron hand were substituted for the kid glove" In spite of this rather forbidding manifesto, the author appears as a likeable and sensible person, whom the psychologist would be very willing to admit as a good influence in his own right and regardless of his theoretical approach Mr Pank's contact with his charges seems on his own showing to have been intuitively sound, and it is unfortunate that he seems to limit his theoretical deductions to his own experience, and even there to document them thinly in demanding the restoration of the birch he adduces no evidence whatever to rebut the very large body of contrary evidence, while his call to the "cranks who are in favour of abolishing punishment" to "themselves try to control over a hundred youths such as ours with no other methods than persuasion" could be met very fully from the records of work such as the Hawkspur Experiment alone It is unfortunate to see a born teacher with an obvious sympathy and understanding for his charges so poorly informed of the work and methods which others advocate, and of the successes they have obtained

Steroid Hormones and Tumors

A LIPSCHUTZ, M D, director of the department of experimental medicine, National Health Service of Chile Baltimore Williams & Wilkins London Baillière, Tindall, & Cox 1950 Pp 309 46s 6d

THIS monograph presents in condensed form and logical sequence the results of 15 years of experimental work by the author and his numerous associates Much of the work is already well known from previous publications on the subject of tumorigenesis and antitumorigenesis with steroid hormones It deals with the induction of those curious fibromatous and fibromyomatous tumours of the abdominal cavity of the domestic guineapig by continuous dosage with œstrogens, their prevention by combined dosage with luteinising hormone, and their disappearance on withdrawal of the originating stimulus Some unpublished data are included The quantitative, timing aspects, and general implications of the experiments are discussed as also are the precise origin and classification of these atypical yet reversible growths The latter discussion is highly valuable

Experimental work dealing with the induction of tumours directly or indirectly by œstrogenic hormone both in his own and in other laboratories is described with a full bibliography The author is always careful to make a distinction between evidence that provides proof of autonomous growth (metastasis, transplantability) and that which does not, at the same time stressing the gradations in response from reversible hyperplasia to full autonomy Contributions and opinions of others are accorded impartial consideration and there is a list of 900 references The whole monograph is illustrated lavishly and well

The Esophagus and Pharynx in Action

A Study of Structure in Relation to Function WILLIAM LERCHE, M D, F A C S, Associate Professor of Surgery, University of Minnesota, Minneapolis, Minnesota Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications 1950 Pp 229 40s

SURGICAL literature badly needs a book about the œsophagus and pharynx in action As soon as surgical technique loses touch with the knowledge of function and the causes of dysfunction patients suffer in vain It therefore seems a pity that a book with so attractive a title should consist of anatomical description of the not only dead but embalmed œsophagus served up with much conjecture

Under the title "rumination" Dr Lerche will [illegible] a detailed dissection of an œsophagus, and then say "Since no clinical history was available my belief that the condition was due to rumination could not be confirmed" He seems to have lost sight of the normal action of the œsophagus in passing food down to the stomach, and he concentrates on how it behaves with fluid and wind coming upwards From the arrangement of a few muscle fibres examined months after death, he deduces that the body was in the process of belching as the spirit fled, he can even assert that half the belch reached the lower segment of the œsophagus while some of the wind frittered away in the upper segments

The author may have spent much time in microscopic dissection of muscle bundles, but, if so, it is all the more disappointing that he has obscured his anatomical work by untenable hypotheses, poor illustrations, and a somewhat misleading title

---

Poisons Guide Volume I (London *Chemist and Druggist* 1951 Pp 89 20s) —This work, the previous edition of which appeared in 1944, has been revised by Mr W A. Whatmough in the light of changes in the poisons regulations, and is now set out in a more easily read form Together with volume II which is being prepared the book is claimed to form an "encyclopædia of poisons law"

Zoogeography of the Land and Inland Waters (London Sidgwick & Jackson 1951 Pp 208 30s) —The world is divided into eight natural geographical regions, and the fauna of each is described here both as it is now and as it was previously according to the geological record Prof L F de Beaufort has successfully compressed his vast material into a small book with a good bibliography and index The account is clear and concise, and the tracking of the fauna that colonised the British Isles is as enthralling as a good detective story

Dible and Davie's Pathology (3rd ed London J & A Churchill 1950 Pp 963 54s) —Dible and Davie's *Pathology* first appeared in 1939 and proved its worth as a standard textbook This edition is brought up to date by Prof J Henry Dible, the senior author, whose wide experience and outlook, both in pathology and bacteriology, have allowed him to introduce much recent work without asking too much of his readers Indeed, the book is a pleasure to read from the introductory homily to the final page The more important and dramatic historical facts are well presented, and the whole subject of pathology is made lucid and stimulating

Emergencies of Childhood (London James Nisbet 1950 Pp 64 6s) —This good short book on first aid, by Dr R Gamlin, is marred by inflated language "Synopsis of general procedure in hæmorrhage control" is not a better, but a much worse, way of saying "what to do for bleeding" The advice is in the main sound, but though it is true that the burned child should be conveyed to hospital as rapidly as possible," it is a pity that Dr Gamlin recommends his readers to apply 'strips of gauze soaked in sodium bicarbonate' It is now generally agreed that only a clean towel or dry dressing should be put on burns Moreover it would be wise to mention that tannic acid or gentian violet should never be applied to burns or scalds which entirely or partly encircle the finger The illustrations are helpful, and it was a good idea to include Dr Breen's pictures of fever rashes

Freud Dictionary of Psychoanalysis (New York Philosophical Library 1950 Pp 208 $3 7) —This is a glossary, edited by Nandor Fodor and Frank Gaynor, of the more important psycho analytical terms, arranged in alphabetical order, illustrated by brief extracts from the writings of Sigmund Freud himself Reference is made, alongside each extract to the work in which it occurs, and there is a key at the beginning of the book to the various writings A chapter and page reference might usefully have been included with each extract for those interested in tracing each definition to its source and studying it in its relevant context There are some surprising omissions, such as the terms abreaction, anaclitic, economic, metapsychology, omnipotence, organ pleasure and reaction formation, space for which might well be found in a further edition by pruning some of the terms which Freud does not use in any but the ordinarily accepted sense—such as beauty phantasy, and intoxication

THE LANCET

LONDON SATURDAY, MAY 5, 1951

Priorities

PARLIAMENT is likely, it seems, to agree to the proposed charge on dentures and spectacles though not without misgivings, for this departure from the cherished principle of a comprehensive health service open to all, without individual payment, may open the way to further and more hurtful impositions. Last week, when the Bill empowering the Minister to make these charges came before the House of Commons for its second reading, the Minister of Health was at least able to dispel concern that this move had been dictated by the Treasury. The Chancellor, he said, had raised by £7 million last year's ceiling for expenditure on the National Health Service, but the Minister and the Secretary of State for Scotland had found that, even with the new aggregate allotment of £400 million from the taxpayer, they would still have a deficit of £23 million. This they reduced to £13 million by curtailing the original hospital estimates, and the remainder was to come from the new charges, which this year would yield the necessary £13 million but in a full year would yield £25 million. Mr MARQUAND declared that in deciding on these charges he had had four aims in mind: (1) to maintain the essential parts of the service, (2) to spare the seriously ill, (3) to avoid a high cost of collection, and (4) to deter abuse. The prescription charge, previously proposed but never enforced, satisfied the fourth criterion, but none of the others, and he had decided against a "hotel" charge in hospitals because most patients had lost their wages and received only sickness benefit, which anyhow was reduced after eight weeks' stay. But what if a further retrenchment proves necessary in the future? Each year since the service started its cost has risen, with the upward adjustment of salaries and wages and inflationary pressure, and the extra £12 million from dentures and spectacles in a full year will not go far to meet rising prices, let alone finance new developments. No such moderately acceptable solution as has been found this year is likely to come to hand again.

Saving on one or other part of the service—either by cutting expenditure or imposing charges—may be sought for one of two reasons: first to curb extravagance, or secondly to maintain the essentials of the service as the value of the pound falls, by diverting expenditure from one heading to another. It is well to distinguish between these two grounds even though they both happen to underlie the proposals now before Parliament. At the start of the National Health Service—as at the inception of most large ventures—there was a good deal of needless spending, but gradually the loose ends were trimmed, and the trimming process has been hastened in the last twelve months since Sir STAFFORD CRIPPS explained that no further large increase could be countenanced. Undoubtedly some further saving is still possible without detriment to the public or any part of the service, and in last week's debate Dr JEGER suggested that alternative means of economy might be found in encouraging opticians to use the patient's old spectacle frames instead of always supplying new ones, in asking the patient to provide his own containers for medicines, in obtaining dental supplies at a lower cost, and in modifying dental and other fees. But such extravagance as remains is now mainly in the wasteful use of expensive supplies rather than in the scope of their provision, and the effort will have to be directed towards showing those engaged in the service how waste can still be avoided.

The other type of saving—whether it is exercised by reducing expenditure or by introducing a charge—involves altering the balance of the service, because it will reduce either certain facilities or the demand for them. Here improvisation is out of place, and in the debate Dr CHARLES HILL complained with some reason that when charges are imposed, "they should not be slapped on" as these ones were. Who then is to make sure that the service is not thrown out of balance? Perhaps the Minister. But the Ministry is the apex of a tripartite service, and individual experts who might be the Minister's most helpful advisers would be more than human if they did not favour the division they serve. Like health itself, a health service is really indivisible, and the thoughts of many are turning towards better integration both centrally and peripherally. Why, it is asked, should we not have regional councils who would receive block grants enabling them to secure a balanced service for each area? Objections are that no one has yet devised a method by which such councils could be kept within reasonable size while representing every aspect of the service, and that the upheaval would arrest the development of the service at a moment when it is just beginning to take root. Fortunately there already exists another means of achieving the same end. In the Central Health Services Council the Minister has an expert body which is in a position to review the whole service, indeed in the Commons debate the Minister quoted to good effect a committee of the council in support of the charge on dentures. The council's first task would be to examine the apportionment of resources between each of the three branches (the need for such a review declared itself as soon as the Chancellor insisted last year that the service must operate within a more or less fixed upper limit), and its second task would be to list priorities in economy and development. Such a survey should be continuous, and the findings should be published. In this way those who work in the service would have some assurance—which they are now denied—that the balance is sound, and the public would be better able to judge the fairness of any future step to dock expenditure. One factor that may yet bedevil the health service is uninformed public opinion. This danger is described by Professor MCKEOWN[1] when he says:

> "Medical services developed entirely or mainly in response to popular pressure are likely to prove very unsatisfactory. Popular opinion will certainly urge a proliferation of the curative services."

In the final count the major decisions on health-service finance must be political, just as decisions on

[illegible]

pensions or sickness benefits or education are political, but public—and thus political—opinion can properly be shaped by expert and impartial advice Last week's debate underlined the need

Absorption and Distribution of Fat

AFTER seventy years' research physiologists are still not quite certain how fat is absorbed FRAZER,[1] of Birmingham, has lately brought forward evidence suggesting that both free fatty acids and unhydrolysed fat (i e, "split" and "unsplit" fat) can be absorbed as such from the small intestine, though by different pathways According to FRAZER, free fatty acids are absorbed mainly into the portal circulation and are transported to the liver, while neutral unhydrolysed fat is absorbed by the lacteals and travels via the thoracic duct into the venous system and finally to the storage depots of the body These views are based on observations on rats fed with fats stained with Sudan III When stained neutral fat was fed the dye accumulated in the fat storage depots, whereas when stained fatty acid and glycerol (hydrolysed fat) were given the dye was found mainly in the liver

Clinical investigations have hitherto been confined largely to studies on the excretion of fat and on fat balance SHERLOCK and WALSHE [2] found that in the portal blood of a patient the fat content was not increased after a meal containing butter, but this patient had hepatic cirrhosis, and a fat balance test suggested that fat absorption was abnormal FRAZER's results are reinforced by the clinical observations of Dr AULD and Dr NEEDHAM, reported on p 991 of this issue They administered fats stained with a known quantity of Sudan III to a patient with nontraumatic chylothorax and estimated quantitatively the dye in the fat recovered from the chyle in the pleural cavity Each test was made two hours after a light fat free breakfast and after emptying the pleural cavity of most of the chyle When stained neutral fat was administered about 21% of the Sudan III was recovered from the chylothorax, whereas when the equivalent amounts of stained fatty acid and glycerol were given no dye was recovered in one instance and only a small quantity in another This last result was attributed to the patient inadvertently receiving some neutral fat in the form of butter and an egg It would thus seem that neutral fat was absorbed and distributed, although not wholly, via the chylolymphatic route and that hydrolysed fat travelled in some other manner, since no Sudan III reached the pleural cavity although chyle accumulated as well These observations support FRAZER's view that the two kinds of fat, neutral and hydrolysed, are absorbed by different routes—neutral fat via the lymphatics and fatty acids via the portal system Why two different routes should exist is not quite clear The division may depend on particle size, fatty acids and their salts being of molecular size, and neutral fat particles 0 5 μ or less in diameter

Emulsified fat can be absorbed direct from the blood stream SHAFIROFF and MULHOLLAND,[3] of the New York College of Medicine, and STARE and his co-workers,[4] at Harvard, have shown that fat emulsions can be given intravenously to ill and emaciated patients with perfect safety, and that such fat can be utilised just as easily as fat taken by mouth The New York workers obtained the best results with a preparation containing a 10% protein hydrolysate, 6% gelatin, and 50% glucose, and provided enough was infused a positive nitrogen balance was maintained Administration of the preparation over long periods produced pyrexial reactions in some patients, but no other untoward effects Liver and kidney function were not impaired, lipoid pneumonitis was not observed, and liver biopsy on some of the patients showed the presence of stored fat, but no infiltrative or parenchymal degenerative lesion The oxygen uptake rose just after the infusion, indicating that the fat was being oxidised, but a mild acetonuria and transient ketonæmia showed that oxidation was incomplete The Harvard workers report similar results, and they have traced the pyrexial reactions to the presence of pyrogens in the commercial oils Using tracer elements, SHAFIROFF et al [5] have shown that a considerable amount of the infused fat is utilised They followed the fate of the fat by infusing an emulsion of linoleic acid hydrogenated with deuterium, an isotope of hydrogen The oxygen uptake rose sharply after the infusion, and some 50% of the fat was excreted within twenty four hours via the lungs as water vapour and carbon dioxide Similar tests by others on animals have shown that the remainder of the fat is converted into phospholipids and deposited in the fat depots [6]

Further observations with tracer elements incorporated in fat molecules may soon complete our knowledge of fat absorption

Modifications in Gastrectomy

THERE are healthy signs that surgeons do not regard with unqualified satisfaction the results of the popular Billroth II type of gastrectomy It is surprising that an operation which converts the duodenum into a diverticulum and re establishes the continuity of the food channel by joining a loop of jejunum to the stump of stomach should work satisfactorily in three quarters of the cases such extensive modifications of normal physiology seldom turn out so well But in 25% of patients the operation substitutes new symptoms for old, and it is this which has set surgeons looking for modifications of old procedures, or new operations, to alleviate peptic ulcers The cardinal difficulty in dealing surgically with peptic ulcers is that the most reliable way of decreasing the flow of gastric juice (which is the immediate cause of the ulcers) is to ablate the cells which produce it The ablation creates two new problems The first is the shortage or absence of gastric juice in the digestive processes, which may lead to nutritional deficiencies [7] The second is mechanical The gastric reservoir after operation, unguarded by an exit sphincter, is so decreased in size that food, prepared only by the teeth and the saliva, is tipped in considerable quantity straight into the jejunum The small intestine, which is particularly trouble-free if treated properly, may “kick” when given jobs for which it was not designed, and “dumping” symptoms are the result

Nutritional deficiencies are probably inherent in any effective operation for peptic ulcer, but these can be remedied by appropriate therapy Mechanical troubles cannot be so easily overcome, and the search for more satisfactory alternative techniques has been very active in the past few years Vagus resection was one attempt to surmount the disadvantage of extensive gastric resection In its pure form it has been found wanting, and judgment must be reserved on its merits when it is added to other modifications of the stomach, such as pyloroplasty it was years before plain gastro enterostomy was discovered to be unsatisfactory A return to the Billroth I operation, in which the stump of the stomach is anastomosed to the duodenum, has been made in some clinics The operation is more difficult to do than the Billroth II procedure, and it may be impossible if the duodenum is extensively scarred by ulceration, but the results are claimed by those experienced in the technique to be excellent and to show a very low incidence of dumping Time and further results will show whether the Billroth I operation is staging a serious “come back”, but, though it preserves duodenal function, it must still suffer from the disadvantage of leaving a small stomach which lacks a pyloric sphincter AYLETT[8] has recently described an operation in which the pylorus is transected and the duodenal end closed The jejunum is divided a few inches below the duodenojejunal flexure and its distal end anastomosed to the pylorus, its proximal end is then put end to side into the body of the stomach, and bile and pancreatic juice thus run directly into a normal sized stomach and neutralise its acidity

The latest attempt to decrease the peptic activity of the stomach while retaining its function as a reservoir is described in this issue by Mr MORONEY He has made use of a segment of transverse colon, isolated except for its mesentery and blood supply, and has swung it upwards to bridge the gap between the stomach and duodenum which is left by an ordinary gastric resection The size of the “stomach” is thus preserved, it has motility, and most of its new lining secretes quantities of protective mucus but no peptic juice The function of the duodenum is preserved, and restoration of the continuity of the colon presents no difficulty The 22 cases which MORONEY reports, though all the patients are well, are too slender a basis for a considered judgment of the operation's merits, but the idea is interesting and the early results seem exceedingly satisfactory The idea of colon replacement of the stomach has also been put forward by LEE[9] (whose report reached this country after we had accepted Mr MORONEY's article) LEE, impressed by the deplorable nutritional state of some patients after total gastrectomy for carcinoma, has proposed using the ascending colon to replace the stomach His technique is to divide the ileum just proximal to the ileocæcal valve and the colon in the region of the hepatic flexure, and to swing the isolated right colon into the place left by a total gastrectomy The stump of ileum is anastomosed to the œsophagus, and the colon end of the isolated loop to the duodenum, and continuity of bowel is restored by an ileo-transverse colon anastomosis This operation has been done 3 times by LEE without mortality, but it is clearly much more formidable than MORONEY's technique, and thus it could never be more than occasionally suitable in cases of peptic ulcer

Meanwhile a Billroth II type of operation must remain the standard treatment for peptic ulcers requiring surgery It is known to give a high proportion of satisfactory results and to carry a low mortality Progress is only possible if new ideas and operations are tried, but the essentials in such trials are that they should be made only by highly competent people, well versed in accepted techniques and assisted by proper follow up facilities The gastro intestinal tract in man is unfortunately very different from that of animals, and the results of a new operation for gastric disease cannot be predicted from operations on dogs As, however, it is necessary to make the final experiment on man, let the experimenters make sure that no lesson escapes them, and let the rest of us wait till the results of the experiments are known before repeating them ourselves

Annotations

HYALURONIDASE IN LOCAL ANALGESIA

FOR nearly twenty years[1] it has been known that certain tissue extracts and bacterial products contain a mucolytic enzyme, now known as hyaluronidase, which causes the rapid spreading and disappearance of fluids injected into the subcutaneous tissues Hyaluronidase hydrolyses hyaluronic acid, a viscous polysaccharide present in the interstitial spaces making it less viscous so that aqueous solutions penetrate the tissues more easily The effect of the enzyme lasts for about 24 hours after injection

At the moment hyaluronidase is of most clinical value when used for subcutaneous infusions in infants,[2] and it is widely employed for this purpose However, the first clinical report on hyaluronidase[3] dealt with its use as an aid to local analgesia, and two years ago Kirby *et al.*[4] reported that by mixing hyaluronidase with a local analgesic it was possible to anæsthetise a larger area of skin Then last year Moore[5] studied the effect of injecting hyaluronidase and amethocaine in a series of over 500 nerve blocks, and found that the mixture had a more rapid analgesic effect than amethocaine alone but that the effect lasted for a shorter time unless vasoconstrictors were used as well Hyaluronidase enabled fluids to pass through areolar tissue but not through fascial barriers The method was most successful when used for nerve blocks for hernia operations, and in splanchnic block A disadvantage was that the rapid absorption of the analgesic made toxic reactions more likely Thorpe[6] has lately described how he manipulated a fracture painlessly after the surrounding hæmatoma had been injected with a mixture of procaine and hyaluronidase Analgesia was rapid and complete, and the effect lasted for more than an hour It is always difficult to insert the needle accurately when injecting deeply placed nerves, as in splanchnic and paravertebral blocks, and also where bony landmarks are indistinct, as in inguinal hernia blocks In such cases hyaluronidase is likely to be of special value, since the spreading of the solution will make a successful block more certain

THE PROPER USE OF PUNISHMENT

THE practice of ignoring inconvenient evidence, though a common enough human failing, sits uneasily on members of the legal profession Lord Goddard's conviction, quoted by Dr F R C Casson in our correspondence columns, that young offenders need more punishment and less psychiatry is shared by many a simple business man and surburban housewife—people who have not encountered evidence to the contrary, or learnt to weigh opinion against fact Yet, as we point out in a review of Mr Dudley Pank's book, evidence has been steadily accumulating for many years now that the best results with young offenders are not to be obtained by " more punishment " The reason, as Dr Casson points out, is that no one "learns" from the severity of those whom he regards as oppressors The attitude of the young delinquent to punishment, he says, can only be understood " in terms of a prisoner of war resisting and resenting the stern measures of his captors " His loyalties are elsewhere , and until they can be won to the service of society he will remain a rebel Mr C A Joyce's[1] methods at the Cotswold School are a living reminder that violence is seldom a useful form of punishment , and that penalties, to be constructive, must appear to the delinquent not as examples of adult despotism but as something he brings down on himself by his own free choice Possibly this is the use of punishment which Lord Goddard had in mind

CUTANEOUS ANTHRAX

FORMERLY cutaneous anthrax was fatal in about a fifth of untreated cases , and the disease should always be suspected when a patient has a red macule on the skin of the face, neck, forearm, or hands which becomes vesicular in the centre and later acquires satellite vesicles A history of exposure to infection helps in diagnosis , but as Dr Doig and Dr Gemmill show in their article this week, the chain of infection may need some unravelling Among those primarily exposed are dockers and others handling goat hair and animal tissues before these are decontaminated Soltys[2] has reminded us, too, that laboratory workers and students handling stained films of anthrax are also in a dangerous occupation The organism gains entry through skin abrasions , and methods which reduce the number of minor injuries, such as mechanical aids in handling and the wearing of gloves, are of preventive value People working with infected material should have ready access to 2% tincture of iodine or some other effective local application For treating malignant pustule Sclavo's antiserum appears more often in textbooks than in wards, and large doses of penicillin are now commonly used Ellingson et al[3] successfully treated 25 cases of cutaneous anthrax with 30,000 units of penicillin every three hours, the total dosage being between 1 and 2 million units 'Aureomycin' has also been found to be curative, and now Gold and Boger[4] have described 8 cases which were successfully treated with the newer antibiotics—2 with aureomycin, 4 with chloramphenicol, and 2 with 'Terramycin' Bacterial sensitivity tests showed that in each case the anthrax bacillus was fully susceptible to each of these antibiotics, which appeared to be equally useful in controlling cutaneous anthrax Local œdema and erythema did not increase 24–48 hours after treatment was started, but enlargement of the regional lymph nodes continued for several more days , moreover, anthrax bacilli were repeatedly recovered from lesions 2–3 days after the spread of local œdema had stopped, and the organisms disappeared somewhat more slowly with aureomycin, chloramphenicol, or terramycin than has been usual with penicillin All but 1 of the 8 patients were treated at home , this is one advantage of using drugs which are given by mouth Meanwhile, with at least four antibiotics effective against cutaneous anthrax, Sclavo's white asses can graze in peace

THE HIGH AND FAR-OFF TIMES

BEFORE man walked in on two feet, prehistory was occupied, for more than 500 million years, by a great deal of other livestock , and in his latest exhibition, "Prehistoric Man in Health and Sickness," at the Wellcome Historical Medical Museum, Dr E Ashworth Underwood has found it as hard as our primitive ancestors to keep out the mammoths and the sabre toothed tigers Even a dinosaur, who left the mortal scene some 70 million years before *Homo sapiens* came upon it, has wriggled his way into this fascinating exhibition, by dint of a hæmangioma affecting two vertebræ near the end of his tail This massive specimen in which the tumour is as big as a grapefruit and the vertebral bodies are almost wrist thick, does much to confirm the sapience of man To attempt to share a world with such a creature would have been foolhardy As it was, man had quite enough to contend with not the fauna only, but the weather (four ice ages in 300,000 years), and such common ills of the flesh as gall stones, arthritis deformans, periosteal sarcoma, osteomyelitis, and bad teeth Examples of all these are shown in the exhibition, alongside such interesting dental veterinary problems as a cystoma in the mandible of a four tusked mastodon, a dental abscess in a titanothere, and pyorrhœa in a three toed horse As man only left his bones and his calculi, it is hard to know what less durable ills he also suffered from , but as Dr Underwood points out in his scholarly introduction to the catalogue,[1] bacteria were ready and waiting for him A photomicrograph in the exhibition shows the oldest known bacteria—more than 520 million years old Being calcium precipitating, they have preserved themselves for study But, as usual, man was probably his own worst enemy active rather than thoughtful, he pressed forward to a cure without proper study of causation We have all heard of the neolithic enthusiasm for trephining the skull, and skulls in the exhibition, as well as a life like diorama of the primitive surgeon in action, illustrate the practice Usually the piece removed was roughly circular, and the method was to scrape it out with a flint tool The fragment was then bored with holes and probably worn as an amulet Skulls showing healing of such trephine holes are common, and so are those in which the operation had been performed on two or three occasions The theory is that it was done to relieve headache or to let out an evil spirit, and it seems to have been tried on men, women, and children, impartially Another neolithic operation was cranial cauterisation in a T shape, usually done with boiling oil and only on women

Public health had no place in prehistoric economy The floors of caves or other simple dwelling places consist of packed refuse, in which deceased members of the family were sometimes buried A model shows a pile dwelling such as men built on the shores of the Swiss lakes, and in the diorama mentioned there are huts built sturdily of stones below, with wattle and daub above and a thatched roof with a central smoke hole. Another diorama shows cave dwellers looking down from their cliff on an inexhaustible meat ration of mammoth, woolly rhinoceros, cave lion, reindeer, and horse. Horses figure more often than any other animal in carvings and decorations on tools and weapons—a tribute, no doubt, to their flavour.

Whatever the shortcomings of primitive man as a surgeon and a sanitary inspector, his position as an artist is now established. This exhibition shows many splendid examples of his work—weapons (including a beautiful spear thrower carved from reindeer antler in the form of a horse), carved ornaments, and those wall paintings of bison and other animals which are now so familiar, though so recently discovered. These are shown beautifully on transparencies against the windows. The later primitive cultures produced delicately ornamented pots, combs, and jewellery, and an elegant display shows how early was the idea of the safety pin and how ornamentally it was used. Weaving came far earlier than we are apt to think; flaxen homespun has survived from the Swiss lake dwellings. Weapons and tools in great profusion show primitive man's skill with his hands—delicate flint knives like leaves, bone and ivory fish spears, stone axe heads, and all the necessities of an arduous and extraverted life. This is an exhibition not to be missed by anyone with the least curiosity about man's origins and career.

HEART SOUNDS AGAIN

LIKE all good things, the stethoscope has at times been misused; but this does not excuse the disdain with which it is now sometimes regarded. Curiously enough, it is our American cousins who, prompted largely by experience in the late war, have leapt to the defence of this Victorian insignia. These proponents have found a brilliant leader in Samuel A. Levine, of Harvard. His grouping of heart murmurs into six grades may be open to criticism, but it does provide the learner with a useful guide.

The importance attached to auscultation by the American Army is well exemplified by Johnson,[1] who remarks that men with a grade III or louder systolic murmur are rejected for military service regardless of other evidence. Similarly, the presence of a grade I apical systolic murmur is taken as ground for rejection if accompanied by an authentic history of rheumatic fever; while a grade II murmur which is not completely dispelled in certain phases of respiration will also cause rejection. An even firmer line is taken with murmurs in the aortic area; a localised systolic murmur of any intensity (unless grade I) is a cause for rejection. In the pulmonary area—the "area of auscultatory romance," as it has been described—a murmur can be disregarded if it is grade I or II in intensity and if there is no other sign of heart disease. Proven rheumatic heart disease is undoubtedly a sound reason for rejecting an army recruit, but it is no barrier to an active civilian life. Deciding the extent of physical activity permissible to a patient with rheumatic heart disease is a matter of sound clinical judgment in which are weighed a full clinical history and physical examination, and a knowledge of the patient's family background such as only the family doctor can attain.

In discussing the role of auscultation in cardiology certain practical considerations are too often neglected. The ear pieces must fit the ears comfortably, and rubber tubing must be of reasonable thickness (the tubing used for bunsen burners is ideal, and has the further advantage of cheapness) and length (an inch longer than the maximum jumping distance of the flea is a sound working rule). The question of end pieces is easily solved; two end-pieces (not a double one) should be bought—a bell and a diaphragm type—but many clinicians will prefer to adhere to one type, contending that with long experience skill becomes greater than with two. As an ancillary to the stethoscope, particularly for detecting early aortic diastolic murmurs, the advantages of direct auscultation should never be overlooked; many an early case of aortic incompetence has been missed because direct auscultation was not carried out to the left of the mid sternum with the patient leaning forwards and holding the breath in full expiration. Finally, the examination room must be quiet. If only doctors would refuse to examine patients in the bedlam of so many outpatient and examination centres, the authorities would be compelled to act.

The stethoscope will long remain an essential instrument for the clinician. As Levine[2] points out, "in the present era, where complicated apparatus, such as the X ray and the electrocardiograph, are often essential adjuncts in diagnosis and treatment, and when the cost of medical care is necessarily increasing, it is imperative to derive all possible help from such an inexpensive and expedient tool as the stethoscope."

CLEAN CATERING

THE caterer, who once chose proteins languidly from the joints of the world's herds, now wears the strenuous and devoted look of the collector of rare specimens. His profession is becoming more exacting in other ways, too, for the report of the Catering Trade Working Party,[3] under Sir William Savage, is helping to foster a common prejudice in favour of clean food. King Edward's Hospital Fund for London has long urged on the hospital caterer the advantages, from the point of view of patients, of clean well run hospital kitchens. Its School of Hospital Catering, which is shortly to open at St. Pancras Hospital, London, is to offer refresher courses to all categories of staff in hospital catering departments, and a useful innovation will be a basic cookery course for untrained staff. The Fund has already published several circulars on the problems encountered by the caterer. The latest of these[4] draws a comparison between the standard of cleanliness demanded, and maintained, in the operating theatre, and that countenanced, even accepted, in some hospital kitchens. The theatre staff are highly drilled in ritual cleanliness; the kitchen staff as a rule are not. The theatre staff, even the most junior nurse among them, have had specific teaching in bacteriology, whereas the head cook usually knows as little about germs as the junior kitchen-maid—possibly less.

> 'To maintain the best hygienic standard,' the circular reads, 'catering staff must be given proper facilities to carry out hygienic practices such as washing up in two sinks with adequate hot water of a sufficient heat to avoid the use of drying cloths, and practise personal hygiene such as washing the hands after visiting the toilet.'

For, as the circular goes on to point out, the most hygienic equipment and layout are useless if the staff fail to keep the rules of hygiene. Why should they keep rules which they do not understand? Why should they practise a piece of tedious and time consuming magic in answer to a notice on the wall? They need, as the circular insists (though not until the very last paragraph), to be taught underlying principles.

The introductory paragraphs of this well intentioned document set out the causes of food infection, but in such an elementary and telegraphic way that they will hardly impress an uninformed reader. The assertion that "fatal cases of food poisoning have occurred from infection of food from a sore on the finger of a Cook" needs at least one example to give it force Moreover, the circular abounds in vague phrases which badly need backing by descriptions, measurements, and figures Thus the washing of crockery must be carried out "under proper conditions," attention must be given to the "proper disposal" of swill, cold storage space must be "adequate," the standard of kitchen hygiene "satisfactory," the premises "large enough," and "adequately lit," hot water must be provided "for all requisite purposes," there must be a "sufficient" number of wash-basins for the staff, steam for sterilising food containers should be available under "adequate pressure" and "an adequate time of steaming is essential," and detergents should be used in "correct strength" These weaknesses apart, the circular gives much useful general information, noting that food infected with small numbers of food poisoning organisms may be harmless if eaten soon after preparation but dangerous if allowed to stand in a warm atmosphere for a few hours, that kitchen floors should be hard, uncracked, and easily washed, that water closets should have adjacent wash basins, and that kitchen sinks should not be used for hand washing, that dish washing machines should also sterilise, that staff should wear light coloured gowns and caps, and that vermin should be kept down It recommends that, in order to limit the infection of food, food handlers should report to the manager if they are suffering from a discharging wound, sores on hands or arms, discharging ears, diarrhœa, vomiting, or any other illness, and that the manager, should he learn of such illnesses, should send the affected member of the staff off duty Any applicant for a post who has suffered from typhoid or paratyphoid should be referred to the medical officer of health and not engaged without his approval. These sound proposals are part of a target code laid down by the Working Party—nothing short of which, the circular rightly asserts, should be entertained by hospital caterers

TREATMENT OF BRUCELLOSIS WITH ANTIBIOTICS

UNTIL 'Aureomycin' and chloramphenicol were discovered the treatment of brucellosis was unsatisfactory Combined administration of streptomycin and sulphadiazine can apparently bring about a cure, but this method requires very careful supervision, and streptomycin is not free from toxic effects The response to aureomycin and chloramphenicol is rapid and toxic manifestations are few, but the relapse rate is high, this averages 22%, and Knight et al [1] have reported 6 relapses in a series of 13 cases

'Terramycin,' the antibiotic obtained by Finlay and his co workers [2] from cultures of *Streptomyces rimosus*, is also said to be effective against *Brucella melitensis* Killough et al [3] gave a daily total of 50 mg per kg body weight in divided doses every four hours, treatment was continued for one to two weeks after the patients became afebrile, and no serious side effects were noted Terramycin proved as effective as aureomycin or chloramphenicol in controlling pyrexia and the acute symptoms, the patients became afebrile within $3^1/_2$ days of starting treatment Unfortunately the clinical relapse rate was 50%, and a further 19% had a bacteriological relapse, making altogether 69% relapses This compared favourably, however, with two similar series treated with aureomycin and chloramphenicol, where the relapse rates were 73% and 66%

With these fairly small numbers comparison is difficult, but it does look as if terramycin is just as effective as aureomycin and chloramphenicol in the treatment of brucellosis The fairly high proportion of patients with bacteriological relapse without signs or symptoms underlines the value of repeated blood and urine cultures after stopping treatment The acute manifestations of brucellosis can be controlled by antibiotics the problem of preventing relapse has still to be solved Possibly a combination of antibiotics may be better than any one alone

LAST WORDS OF A TEACHER

To countless friends in many countries, Dr Alfred E Barclay became affectionately known as "Uncle B" His generous and friendly disposition made him always ready to help and encourage others, and his last book,[1] published posthumously, is not only a thought provoking account of a new technique, and of some older ones, employed in radiology, but an intentional legacy "to those who follow after"

On retiring he planned a long voyage to Bali, New Zealand, and elsewhere, with the prospect of indulging his bents towards music, fishing, golf, and gadget making in his private workshop on his return, but he was invited to come, for a trivial financial recompense, as radiologist to the newly founded Nuffield Institute for Medical Research at Oxford Almost without hesitation, he agreed to come as soon as his voyage was over, and from 1936 to his death in 1949 he served the institute in an honorary capacity, rounding off the achievements in clinical radiology of his earlier years with the even more remarkable research achievements of his later ones Though he never knew it, the use of the relatively short X rays which made micro arteriography possible was one of the technical possibilities listed in the original scheme for the radiological wing of the institute, and the problems involved came to be tackled by Barclay in his last few years They became specially obvious during the studies of the renal circulation, carried out during 1945–47, when radiological methods had led on to histological ones, and when these in their turn were proving to have their limitations Beginning as an adjuvant technique to the histology, the method of micro arteriography, thanks to the improved war time production of fine grain emulsions, emerged, in Barclay's skilled hands, relatively quickly as an independent method for a new appreciation of the more minute structures in the blood vascular system This last book contains accounts of its initial, very successful, application to the kidney, stomach, and testis (this section by Prof R G Harrison) illustrated with truly amazing radiographs Apart from its main subject, the book deals with research apparatus and protection, with cineradiography, and (in a chapter by Professor Harrison) with selection and injection of contrast media In general, therefore, it describes the radiological precautions and techniques employed at the Nuffield Institute for Medical Research during Dr Barclay's years there, and is his legacy, as a craftsman, to his successors But it contains also his thoughts on the bearings of his and his colleagues' researches Those who have learnt so much from him, and those who have still so much to learn, will always regret that it was not available in time for the International Radiological Congress in 1950, and that he did not live to see it appear

---

THE next session of the General Medical Council will be held on Tuesday, May 22, at 10 30 A M, when Prof DAVID CAMPBELL, the president, will deliver an address The Medical Disciplinary Committee is expected to sit on Thursday, May 24, at 10 30 A M

OBSERVERS' ERRORS IN TAKING MEDICAL HISTORIES

A L COCHRANE
M B Camb

P J CHAPMAN
M B Brist

P D OLDHAM
M A Oxfd

From the Pneumoconiosis Research Unit of the Medical Research Council

ALTHOUGH medical disagreement has long been recognised as common and was publicised by Alexander Pope (1732), there appears to be some general reluctance to recognise it as due to the subjectivity of medical judgment and even more reluctance to investigate it quantitatively Certain recent tendencies have, however, made the recognition and measurement of medical error desirable

In the work of our unit, for instance, it is necessary to correlate medical observations on workmen with the physical characteristics and quantity of the dust they have breathed In doing this, just as the imprecision of the physical measurements must be allowed for, so, similarly, it is necessary to estimate how much one medical observer varies when he repeats his observations on the same material (intra observer error) and how much his observations differ from those of another (inter-observer error), for in large scale surveys several observers must cooperate and their results must be comparable

Although relatively few studies have been published on the subject of medical error, several different approaches can be distinguished In some cases—e g, in the study of cyanosis (Comroe and Botelho 1947)—it has been possible to compare a clinical estimate with some objective accurate measurement of the same characteristic Similar but less accurate measurements have been used by Birkelo and Rague (1948) and Cochrane et al (1949) to estimate the accuracy of radiological prognoses by following up minimal tuberculous lesions Cochrane et al. introduce a slight refinement in technique in that an estimate was made of the number of prognoses that would have been made accurately by chance, the results being expressed as the percentage of the errors expected of a "blind" radiologist which were avoided by the reader Such a refinement is obviously necessary when there are relatively few possible choices

In other studies no objective standard was possible and attention was focused chiefly on the inter observer error These studies were mainly confined to estimates of human nutrition (Bean 1948, Derryberry 1938, Jones 1938), although Britten and Thompson (1926) and Sydenstricker and Britten (1930) have suggested that a similar error is attached to routine clinical examinations

Recently there have been several detailed studies of the intra observer and inter observer errors in the diagnosis of pulmonary tuberculosis (Birkelo et al 1947), pneumoconiosis (Fletcher and Oldham 1949), and pulmonary fibrosis (Hebert 1939) In all these cases the simple repeat technique was applicable, for the subjects of the examinations were not altered by the first investigation Difficulties arise when the first examination is likely to affect the results of the second, as is clearly the case in taking a medical history The general problem is discussed at some length by Kinsey et al (1948), who emphasise that the second interview is influenced by the first, and require a minimum of eight months between interviews

In large scale surveys of coalminers carried out by this unit we wished to know the proportions of men complaining of various symptoms and showing various degrees of radiographic abnormality at a particular time, and a method such as Kinsey's would be impossible

We have therefore approached the problem from a rather different point of view If a population is divided into groups by some purely random method, the proportion giving a positive answer to questions asked by the same observer should be very similar in each separate group The limits outside which the proportions have a small probability (say 5%) of falling by chance can be calculated If then the population is divided into groups at random and each group is seen by a different observer, proportions of positive answers differing by more than the amount expected will be assumed to show that observers are either obtaining different answers from patients in the same clinical state or are interpreting the patients' answers differently

MATERIAL AND TECHNIQUE

During a survey of an English coalmine 993 underground workers were interviewed Observers A, B, and C did the bulk of the interviewing Three other observers, who saw somewhat fewer miners, are called "observer D" The numbers of miners seen by each observer were as follows

Observer	*No interviewed*
A	261 (*26 3%*)
B	250 (*25 2%*)
C	300 (*30 2%*)
D	182 (*18 3%*)
Total	993

All the interviews took place in the same room under apparently identical conditions Usually a queue formed, and the men took the places in order as they fell vacant At slack periods it was rather difficult to tell whether the men chose the observer or the observer the man There was probably a little of both. Three observers were usually present in the room at the same time and could easily overhear each other's questions, and every effort was made to standardise technique The men were asked, in such a way that simple positive or negative replies could be made, whether they had cough, sputum, pain in the chest, tightness of the chest, or shortness of breath, and whether they had a history of bronchitis, pneumonia, pleurisy, or dyspepsia The interviewing had to be done very quickly, since miners were usually seen at the end of a shift, when they were anxious to get home The average time taken was about 5 minutes per man

TABLE I—AGE DISTRIBUTION OF MEN IN EACH GROUP

Age (yr)	No of men seen by observer				
	A	B	C	D	Total
14–19	21 (*8 0%*)	18 (*7 2%*)	14 (*4 7%*)	5 (*2 7%*)	58 (*5 8%*)

RESULTS

To discover whether observers A, B, C, and D had been interviewing similar samples of the total population, the age distribution of those seen by each observer was determined (see table I) Although the men seen by observer B had a slightly higher mean age than the others, the difference is not statistically significant, for it might occur once in eight times by chance alone Years underground and the prevalence of pneumoconiosis have found to be closely related to age, and it seemed reasonable to proceed on the assumption that the necessary random clinical composition of the groups seen by each observer had been attained

Fig 1 and table II show the percentages of men in each observer's group who gave a positive answer when asked whether they had cough, sputum, pain in the chest, tightness of the chest, or shortness of breath on exertion

Fig 2 and table III show the percentages of men in each group who gave a past history of bronchitis, pleurisy, pneumonia, and dyspepsia The probability that these differences were due to chance is given in the last column of each table Accepting as the level of significance that the difference would not have occurred more often than once in twenty times by chance, we find that there was a significant difference in the observers' recordings of the frequency of cough, sputum, pain in the chest, and dyspepsia

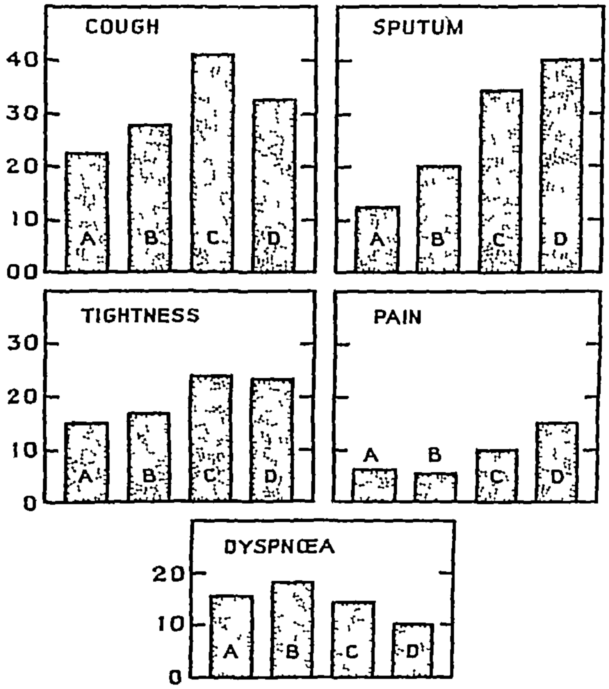

Fig 1—Symptoms found by each observer

DISCUSSION

Our results suggest that the recording of patients' answers to simple questions may, in some cases, give results that are unaffected by the observer In the case of a past history of bronchitis, pleurisy, or pneumonia the question " Have you ever had ? " is straight forward, and the answer in most cases will be " Yes " or " No," which will be thus recorded

The consistency between the observers' recordings, however, does not mean that the answers are necessarily correct Their accuracy must have depended on the memory and cooperation of the men who were asked the question, but men with good and bad memories or high and low levels of cooperation were presumably randomly distributed throughout the group In the other questions, however, the observer had to interpret the man's answer before recording it For instance, to the question " Have you a cough ? " or " Do you spit ? ", the man might reply " Only an ordinary cough " or " Only after work " (for miners commonly cough up a little black phlegm after the shift) The observer would then have to ask supplementary questions to decide whether or not the severity of the cough constituted a symptom of chest disease, and his ultimate recorded answer would depend as much on his judgment as on the man's answer This is presumably why, in these cases, we find very different frequencies recorded by different observers

TABLE III—NUMBER AND PROPORTION OF MEN IN EACH GROUP WHO GAVE A HISTORY OF HAVING HAD CERTAIN DISEASES

Disease	No of men seen by observer				Probability (%)
	A	B	C	D	
Bronchitis	32 (*12 2%*)	26 (*10 4%*)	31 (*10 3%*)	21 (*11 5%*)	80–90
Pleurisy	24 (*9 2%*)	21 (*8 4%*)	31 (*10 3%*)	23 (*12 6%*)	50
Pneumonia	30 (*11 5%*)	36 (*14 4%*)	45 (*15 0%*)	24 (*13 2%*)	50–70
Dyspepsia	26 (*9 9%*)	40 (*16 0%*)	70 (*23 3%*)	49 (*26 9%*)	<0 1*

* Significantly small

In the case of shortness of breath on exertion, which is normal to some extent in health, the observers had agreed before the survey on a careful grading The miners were asked if they could keep up with their fellow workers of their own age while walking Our results seem to show that such a system helps to reduce observer error if it is properly used Errors due to faulty answers will remain

In the case of dyspepsia there is once more an infinite gradation from healthy men who feel bloated after Christmas dinner to the true case of peptic ulcer , hence the observer's judgment once more enters into his recorded answer Presumably the error that we have shown could have been lessened by more careful definition, as in the case of dyspnœa

We believe that our results demonstrate that, at least in this particular survey, the recorded answers to several questions commonly asked in taking clinical histories were not reproducible from one observer to another, so they could not be considered objective scientific observations Possibly if the observers had been more experienced clinicians, or if they had worked more slowly, their results would have been better Observer A was an experienced clinician of consultant physician status, and observers B and C could fairly claim to be well trained in academic scientific medicine, which might be considered at least as important as clinical experience for the accurate and consistent recording of men's answers The composite observer D would be expected to be exceptionally accurate, for the

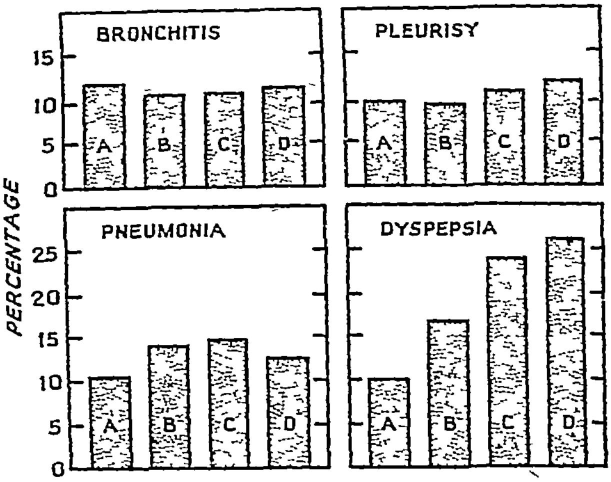

Fig 2—Past medical history found by each observer

proportions found by D are a kind of average of those found by the three observers included in D, the inter-observer error of the three being thus partially averaged out For this reason the discrepancies found are likely to be underestimated In view of the slightly higher mean age of the men seen by observer B it is interesting to observe that his results are in only one case more extreme than those of observers A, C, and D

The work was certainly done quickly, but little faster than some of the work done in hospital outpatient departments or in the consulting rooms of general practitioners Possibly miners are a particularly difficult group, because so many of them have the slight degree of cough and expectoration after work to which we have already referred

In spite of these reservations we believe that our findings have some general application, they are certainly important in clinical field surveys Unless different observers can obtain consistent answers to questions from comparable groups of witnesses their findings are of little scientific value If this were generally recognised, a great deal of misplaced research endeavour would be saved, and many publications would gain in validity what they lose in length We suggest that the technique we have adopted is suitable for investigating the reproducibility of clinical findings

The application of our results to history taking in general is less certain, but many doctors must remember certain curious discrepancies between the histories taken by them as students and those elicited later from the same patients by the house physician or the registrar This inter observer error of hospital history taking would merit investigation particularly if there were any possibility of the histories being used for research purposes later

A further possibility is in the field of medical education A great deal is taught about the art of history taking, its science is badly neglected It should not be difficult to arrange demonstrations for students to show the dangers of leading questions and the invalid deductions that can be made owing to the lack of reproducibility of clinical findings

SUMMARY

A clinical survey of a large number of coalminers was made by several medical observers who interviewed different groups of men The age distributions of the groups were similar The observers all asked the miners in their groups the same questions

The answers to some of these questions showed that the observer's bias was influencing the frequency with which a positive answer was recorded. Other questions were more consistently answered in the different groups

These results are discussed, and it is suggested that more attention should be paid to possible lack of reproducibility in the answers that patients give to questions commonly asked in clinical practice, and that, for research purposes, answers which are not reproducible are worthless

In such large-scale coöperative work it is difficult to apportion credit fairly We should however, like to mention Dr C M Fletcher, Dr J C Gilson, and Dr K J Mann, of this unit, and the 993 miners who answered our questions so patiently and so surprisingly

IMPERIAL CANCER RESEARCH FUND

In his summary of the work done during the past year in the laboratories of the Imperial Cancer Research Fund,[1] Dr James Craigie, F R S, the director, reports investigations on tumour transplantation, tumour induction and progression under hormonal influences, and chemical carcinogenesis in the liver

Dr A M Begg, Miss P E Lind, and Miss Margaret Hayward, PH.D, have collaborated with Dr Craigie in exploring the possibility of developing quantitative methods for the study of transplantable tumours For this purpose a better knowledge of conditions governing cell survival in vitro is essential It was found that tumours could be preserved as cell suspensions in the frozen state provided that dextrose solution was used It was noted that cell suspensions contained a small number of highly refractile bodies similar in size and contour to tumour cells Retention of viability in vitro depended on maintenance of this refractility as seen by phase microscopy Refractile cells were resistant to dextrose solution and to freezing and drying in dextrose —manipulations which kill normal tumour cells

The discovery of a resistant state raises many questions.

Doubtless before doing any further work along these lines, the facts have been taken into consideration that normal cells—liver for example—as well as tumour cells of all kinds actually develop this curious refractile change with obscured nuclear detail in dextrose sucrose and glycerin solutions that the appearance is completely reversible by washing out the sugars or glycerin that it is not to be confused with a similar but irreversible appearance natural to dead pyknotic cells that no normal liver cells whether highly refractile or not, are resistant to immersion in dextrose solutions, and to freezing and partial drying as measured by growth after animal grafting And therefore high refractility is not likely to underlie any property peculiar to tumour cells

Dr Leslie Foulds has extended his studies on the progression of tumours towards malignancy and on their responsiveness to various physiological conditions Observations extended over long periods of intermissions of breeding have confirmed the previous findings that some mammary tumours that regressed after parturition

The work was certainly done quickly, but little faster than some of the work done in hospital outpatient departments or in the consulting rooms of general practitioners. Possibly miners are a particularly difficult group, because so many of them have the slight degree of cough and expectoration after work to which we have already referred.

In spite of these reservations we believe that our findings have some general application, they are certainly important in clinical field surveys. Unless different observers can obtain consistent answers to questions from comparable groups of witnesses their findings are of little scientific value. If this were generally recognised, a great deal of misplaced research endeavour would be saved, and many publications would gain in validity what they lose in length. We suggest that the technique we have adopted is suitable for investigating the reproducibility of clinical findings.

The application of our results to history-taking in general is less certain, but many doctors must remember certain curious discrepancies between the histories taken by *them* as students and those elicited later *from* the same patients by the house physician or the registrar. This inter observer error of hospital history taking would merit investigation particularly if there were any possibility of the histories being used for research purposes later.

A further possibility is in the field of medical education. A great deal is taught about the art of history taking, *its science is badly neglected. It should not be difficult* to arrange demonstrations for students to show the dangers of leading questions and the invalid deductions that can be made owing to the lack of reproducibility of clinical findings.

SUMMARY

A clinical survey of a large number of coal-miners was made by several medical observers who interviewed different groups of men. The age distributions of the groups were similar. The observers all asked the miners in their groups the same questions.

The answers to some of these questions showed that the observer's bias was influencing the frequency with which a positive answer was recorded. Other questions were more consistently answered in the different groups.

These results are discussed, and it is suggested that more attention should be paid to possible lack of reproducibility in the answers that patients give to questions commonly asked in clinical practice, and that, for research purposes, answers which are not reproducible are worthless.

In such large scale coöperative work it is difficult to apportion credit fairly. We should, however, like to mention Dr C M Fletcher, Dr J C Gilson, and Dr K J Mann, of this unit and the 993 miners who answered our questions so patiently and so surprisingly.

IMPERIAL CANCER RESEARCH FUND

In his summary of the work done during the past year in the laboratories of the Imperial Cancer Research Fund,[1] Dr James Craigie, F R S, the director, reports investigations on tumour transplantation, tumour induction and progression under hormonal influences, and chemical carcinogenesis in the liver.

Dr A M Begg, Miss P E Lind, and Miss Margaret Hayward, PH.D, have collaborated with Dr Craigie in exploring the possibility of developing quantitative methods for the study of transplantable tumours. For this purpose a better knowledge of conditions governing cell survival in vitro is essential. It was found that tumours could be preserved as cell suspensions in the frozen state provided that dextrose solution was used. It was noted that cell suspensions contained a small number of highly refractile bodies similar in size and contour to tumour cells. Retention of viability in vitro depended on maintenance of this refractility as seen by phase microscopy. Refractile cells were resistant to dextrose solution and to freezing and drying in dextrose—manipulations which kill normal tumour cells.

The discovery of a resistant state raises many questions.

Doubtless before doing any further work along these lines, the facts have been taken into consideration that normal cells—liver, for example—as well as tumour cells of all kinds actually develop this curious refractile change with obscured nuclear detail in dextrose, sucrose, and glycerin solutions, that the appearance is completely reversible by washing out the sugars or glycerin that it is not to be confused with a similar but irreversible appearance natural to dead pyknotic cells that no normal liver cells, whether highly refractile or not are resistant to immersion in dextrose solutions and to freezing and partial drying as measured by growth after animal grafting. And therefore high refractility is not likely to underlie any property peculiar to tumour cells.

Dr Leslie Foulds has extended his studies on the progression of tumours towards malignancy and on their responsiveness to various physiological conditions. Observations extended over long periods of intermissions of breeding have confirmed the previous findings that some mammary tumours that regressed after parturition recurred after many weeks without the stimulus of a new pregnancy, but that others did not recur although new tumours developed elsewhere in the mammary glands of the same mouse

---

[1] Imperial Cancer Research Fund 48th Annual Report 1950–51 Issued by the Fund, Royal College of Surgeons Lincoln's Inn Fields London W C 2

Dr E Vazquez Lopez has continued his study of the effect of thiourea in decreasing mammary tumour incidence in a strain of mouse with the Bittner agent Although œstrogenic secretion is interrupted for a long period during administration of thiourea, nevertheless the size and differentiation of the mammary glands are equal in treated and untreated animals The purely carcinogenic contribution of œstrogens in this type of tumour production can therefore be established and studied independently of any other manifestation of ovarian activity

Mr H G Crabtree has prepared a number of new azo compounds with the purpose of examining further the concept that *p* aminobenzoic acid and possibly folic acid may be determining factors in the genesis of liver tumours Experiments designed to test the concept will take many months to mature

ROYAL SANITARY INSTITUTE

Southport's sun, sea, sky, and too plentiful sand provided the physical background for a busy time last week for many practitioners of preventive and curative medicine Experts on tropical hygiene, occupational health, engineering and architecture in relation to hospital design, housing and town planning, veterinary hygiene, and the food industry helped to contribute to the forty seven addresses Also present were members of local authorities, engineers, surveyors, sanitary inspectors, health visitors, and not a few general practitioners —over 2000 members of the "health team" in the campaign against disease

THE RHEUMATIC DISEASES

Sir Henry Cohen, in the opening paper, gave an important classification of rheumatic diseases He protested against the domination of labels in diagnosis He estimated that in Great Britain there were not less than 250,000 arthritics—more probably there were twice as many He cautioned against the cry of "cortisone for all", for at $35 per gramme a quarter of a million patients could cost (even if the drug were available) over £112 million per annum He had caustic comment to make on the "meaningless" cry of prevention and on the many valueless contributions, statistical and otherwise, in the rheumatic field Nevertheless, he felt that "never in the history of rheumatic disease has the horizon been brighter"

Dr E T Conybeare followed with a careful scientific assessment of the problems of acute rheumatism and rheumatic heart disease Another quarter of a million persons under the age of 40 had hearts damaged by acute rheumatism The number of new cases every year might be 5000 He quoted Bywaters's recent summary of the now practically overwhelming evidence that infection with *Streptococcus hæmolyticus* (group A) is one of the causes of acute rheumatism and rheumatic heart disease Infection with this organism is, Bywaters says, the "prime factor, not exclusive of other factors, but without which the disease would not exist"

Dr Conybeare felt that overcrowding might be attacked to better advantage, sleeping and other accommodation in all residential communities (and especially those which were educational or military) should be arranged so as to diminish as far as possible the spread of respiratory infection and to control the frequency, weight, and variety of these infections among children and young adults With so much depending on early detection, especially with the sometimes insidious onset, the help of the general practitioner was of outstanding importance The special rheumatism supervisory centres were of help to him The hospital and specialist services, together with local health and education services could provide much useful help in carrying out the important recommendations of the Rheumatic Fever Committee of the Royal College of Physicians

VETERINARY HYGIENE

In the section on veterinary hygiene, Mr W S Davison, M R C V S, re stated the need for a central reference laboratory in investigating infestation of meat by parasites inimical to man

Mr E -R Callender, M R C V S, discussed the eradication of bovine tuberculosis and the financial inducements which were offered to the milk producer and stock rearer, his figures showed the apparent slow progress achieved

HOUSING

Mr Ronald Bradbury, PH D, pleaded for a more realistic basis of housing design to meet the varying needs of different families, from the newly married couple to the large number of aged persons living singly and occupying a big house

FOOD

There was much discussion on the control of manufacture of ice cream and other emulsified food products No one bacteriological test was reliable Miss Betty Hobbs, PH D, thought that risk of infection had been considerably reduced by the operation of the Ice cream Heat Treatment Regulations, 1947, but unnecessary outbreaks of infective disease, particularly those caused by *Salmonella paratyphi B* and other organisms of the salmonella group, still occurred Far stricter control over the manufacture of synthetic cream was needed Many foodstuffs, such as mayonnaise and salad cream, were relatively safer because of their low pH and their content of vinegar

HYGIENE IN INDUSTRY

Dr J N Morris, in the section on hygiene in industry, challenged his audience with the question "What is it we are trying to do?" In the discussion a speaker brought down the house by stating that "most troubles in industrial health are due to sheer laziness!"

ENGINEERING AND ARCHITECTURE

In considering the design of a premature baby unit, Mr P B Nash showed the plans of a new unit, containing 14 cots, designed to accommodate mothers and their babies The unit also provides for demonstration and feed rooms, six "warm" cubicles, and 8 "cool" cubicles

Lieut Colonel E G King described the problems of sewage disposal in seaside towns He emphasised the value of sterilising effluents before discharge into tidal waters in order that amenities on the beach should not be affected

MATERNAL AND CHILD WELFARE

Dr Alfred Torrie, in a human contribution on the problem of placement of children for adoption, said of adoption "the earlier the better" The child's interests were paramount Some neurotic adults wished to adopt children to compensate for the lack of love in their own lives and to try to cure their own neurosis Though breast feeding was in the best interests of the child, if we rigidly followed a rule that every unmarried mother should breast feed her child and then part with it we were *placing a great strain on the mother* The sooner the permanent alternative, mother was found and affectionate bottle feeding begun, the better it would be for the mental health of the child

Dr Torrie discussed the problems of backward children who were *adopted His experience* was that many children who were slower in development than others de up for it later on, those who kept height and ght charts of infants knew that these were helpful understanding week to week progress but were not essarily an indication of what the child would be en grown up To condemn a child to an institution instead of giving it an opportunity to be brought up a family was a very grave responsibility

The psychological problems in placement for adoption olved round the personalities of the adopting parents, ability of the mother to make her own decisions, and need for the child to be adopted at the earliest sible moment More study was required to determine criteria for successful adoption, so that magistrates d others might have something valid to guide them e problems of adoption required a considerable know ge of the factors making for mental health and bility of personality as well as of physical sanitation

Mrs AUSTIN MELFORD, of the National Adoption Society, reiterated the doubts often felt as to whether the motives for adoption were the right ones. It was important to make a wise choice of adopters, and to avoid unhealthy, highly strung, or elderly couples Still greater care was necessary in placing a second child with the same family, and there was more risk of failure where adopters had a child of their own

In the last session, Prof A V NEALE pleaded for the removal of the "iron curtain" between preventive and curative medicine and for greater knowledge of the normal child Undergraduates in particular should examine 'normals" because later they would encounter more normalcy than disorder The training in hospitals might lead to wrong views, for hospitals were filled with "medical failures" Students should have more teaching in the homes of the people

Public Health

PIDEMIOLOGY OF A SMALL OUTBREAK OF ANTHRAX

A T DOIG
MD St And, D.P.H
H M MEDICAL INSPECTOR OF FACTORIES

J S GEMMILL
M B Glasg D.P.H.
SENIOR MEDICAL OFFICER, PUBLIC HEALTH DEPARTMENT, GLASGOW

IN early summer, 1950, three cases of anthrax occurred n Glasgow The first patient, who sickened in May, as a motor-van driver employed by a firm of purveyors nd caterers in a southern area of Glasgow some four iles distant from his home in the east end.

On May 16, 1950 the patient aged 35 returned from work nd, before entering his home had his hair cut at the local arber s shop While a *towel* was being adjusted he received scratch on the back of his neck which made him wince nd he remonstrated with the barber Before leaving he elt the same spot again painful when having his hair brushed On the following day there was a small pimple at the site of he injury which he covered with an adhesive dressing he area, however, continued to itch for some days

On May 21 he suffered from anorexia headache, generalised ains, and malaise, to which sweating was added on the 2nd when he stayed in bed On the 23rd his doctor visited im and treated him for influenza and a boil the dressing aving now been removed for the first time On the 24th e had pain in his left shoulder and now very ill he was een by another doctor who suspected anthrax from the ppearance of the neck lesion and took a smear in which the resence of anthrax bacilli was confirmed by animal inoculation. Penicillin treatment was begun and was at once effective

The patient was seen at home on the 31st by one of us J S G) and was found to be convalescent The lesion consisted of a healing ulcer on the left side of the back of the neck just above collar level the crater was covered by a dry black eschar which measured 1 in horizontally by $^3/_4$ in vertically The appearance was typical of a malignant pustule in the stage of resolution There was also firm discrete adenitis of the posterior triangle and supraclavicular region on the left side but none of the left axilla or on the right side anywhere He had not recently bought or used any new shaving brushes or hair brushes

The patient s place of work and his duties were investigated (A. T D), and these did not appear to bring him into contact with any known or likely source of anthrax infected material. The vans were all motor driven His main duties were to carry trays of foodstuffs from the bakery to his van and then deliver these The goods handled were almost all cooked or baked and seldom contained meat, although on occasion he had to collect meat from a butcher

At this time there was in Glasgow no other patient notified as a case of anthrax.

A visit to the hairdresser s shop showed this to be of a low order of hygiene and management The equipment was modern but the premises were generally dirty and untidy Scissors, clippers, brushes, combs, &c., were said to be sterilised by heat every night They were certainly not sterilised between each customer, the proprietor freely admitted that this was not practicable and was never done He had not recently bought any new brushes, his present stock of shaving-brushes had been in use for a year, and of hair-brushes for two years.

Many of this hairdresser s regular customers were known to be employed at a nearby tannery, and on June 1 two men employed at the tannery—neither of whom was a customer of this hairdresser—fell ill with anthrax These two patients, aged 47 and 50, were seen by us several days after the onset of their illness. In one the lesion was on the left arm and was extremely severe, while in the other it consisted of a typical malignant pustule at the angle of the right jaw, anthrax bacilli were isolated from both lesions Both patients recovered The severe case appeared to be penicillin-resistant but began to make slow progress under treatment with anti anthrax serum and 'Aureomycin', the other case responded well to penicillin alone

On June 6 one of us (J S G) visited the tannery and took samples for bacteriological examination These were (1) floor-sweepings from an area of the store on which a batch of suspected East African hides had been stacked since their arrival in the factory in February and March, 1950, (2) a sample of dry East African hide cut from the edge, (3) a sample of dry East African hide cut from the centre Sample 2 was negative for *Bacillus anthracis*, the guineapig having died of an intercurrent intoxication (*Clostridium welchii*) Samples 1 and 3 were both positive for *B anthracis* on guineapig inoculation Another batch of East Indian hides from the same cargo was responsible for a fourth case of anthrax occurring in another town

COMMENT

It seems reasonably certain that case 1 was infected indirectly in the barber s shop, by contaminated instruments or finger-nails, or both It also seems permissible to assume that this infection was introduced into the barber s shop *on or about* May 16 by a tannery employee whose hair or clothing was contaminated by infected dust, but who himself was not suffering and did not later suffer, from anthrax The assumed path of infection, then, is from the infected hides by means of dust to the hair or clothing of an unaffected worker, thence to the barber s instruments or finger-nails, and finally to the affected person

The facts supporting these *conclusions* are as follows (1) a certain batch of hides in the tannery was proved to be infected with *B anthracis*, which was also present in the dust arising from this batch, (2) a considerable number of employees at the tannery habitually patronised a nearby hairdresser, (3) a man having no other known, or likely, contact with infected material received a wound on the neck while having his hair cut at the same hairdresser's, and a malignant pustule developed at the site of the wound, (4) two cases of anthrax occurred in the third week after this incident in tannery employees who had contact with the infected hides, but had not patronised the hairdresser's shop

Children in Glasgow

The average weights and heights of Glasgow schoolchildren have increased steadily in the last 18 years The following figures for 1950[1] show the average increases for the different age groups since 1932

Age (years)	Increase in average weight and height	
	Boys	Girls
5	2 91 lb 1 37 in	2 66 lb 1 30 in
9	4 84 lb 1 78 in	4 64 lb 1 44 in
13	8 63 lb , 2 30 in	9 46 lb , 1 92 in

Medicine and the Law

Parent's Refusal to allow Operation

In a recent case which must have given the hospital authorities a distressing anxiety a mother persistently refused permission for an operation to be performed upon her infant daughter At the inquest[2] the coroner told the jury that they might have to consider returning a verdict of manslaughter or even murder The jury's verdict was "death by misadventure", they added the comment "We feel that the mother did not sufficiently understand what was being asked of her" In recording the verdict the coroner observed that death was accelerated by lack of adequate treatment owing to the mother's refusal to consent to an operation

The deceased baby, born in June last year, was admitted to the Ipswich Isolation Hospital (on transfer from the Borough General Hospital) with whooping cough Gastro enteritis developed Efforts were made to obtain the mother's permission for intravenous injection, she was told that the medical authorities said that the child's only chance of survival was by an operation She had herself undergone two operations in hospital and had said that she would never have consented to them had she known how severe they would be Since that experience she had dreaded operations There was some conflict of evidence as to whether she had or had not, at one point, assented to the operation on the child, she maintained at the inquest that she had at all times said "no" The doctor in charge of the case, being informed that verbal consent had been given, started the intravenous drip, the operation was not complete when the mother arrived at the hospital and made it clear that she refused to allow it The wound was closed and the operation was abandoned, the infant died next day Medical witnesses could not say that the operation would have saved the child's life, but they considered that it would at least have prolonged it The mother was told that the chances of survival in hospital, if the operation were performed, were fifty fifty, without it they were nil At the inquest the pathologist's evidence was that the recommended treatment was the only useful course, it was not always successful, but in many cases it gave the sole chance of recovery

Apart from any common law obligations to care for a child, the Children and Young Persons Act of 1933 (replacing section 12 of the Children Act of 1908) makes it an offence to neglect a child in a manner likely to cause unnecessary suffering or injury to health, and specifically states that it is neglect if the parent fails to provide medical aid The Act declares that injury to health includes injury to, or loss of, sight or hearing or limb or organ of the body, these words, as Mr Justice Darling pointed out in Oakey *v* Jackson in 1914, indicate that Parliament contemplated that medical aid might include surgical operation In Oakey *v* Jackson the alleged neglect was the failure to allow an operation upon a 13 year old child for removal of adenoids There was evidence that she suffered from mental dullness, impaired breathing, deafness, and some anæmia, and that, though it probably involved anæsthesia, the operation was not a dangerous one The magistrates took the view that there was no legal compulsion upon the parent to allow the operation The High Court held that the facts might amount to a failure to provide medical aid and that, if the facts justified it, the magistrates should have convicted the accused

Two points have arisen in this class of prosecution The fact that parents are poor and could not ordinarily afford to pay professional fees has been no defence to the charge, the medical aid could be obtained through public assistance and today through the National Health Service Secondly, the intention of the accused person needs to be considered The word "wilfully" was explained in 1899 by Lord Russell of Killowen, L C J, in R *v* Senior, where the parent had belonged to the sect known as the Peculiar People and had objected on religious grounds to calling in medical aid or the use of medicine "Neglect," said Lord Russell, "is the want of reasonable care, that is, the omission of such steps as a reasonable parent would take—such as are usually taken in the ordinary experience of mankind" Mr Justice Avory, concurring in those observations, tersely added that one matter the justices ought to consider in such a case is "whether the person who advises the operation is a qualified medical practitioner or merely some irresponsible person"

Parliament

The Health Service Charges

The debate on the second reading of the National Health Service Bill swung between those who regarded the proposed charges for spectacles and dentures as safeguards of the whole service and those who regarded them as a breach of faith and principle Mr **Hilary Marquand** in his lucid review of the Budget proposals declared that the new charges were not a tax on the service but a readjustment of its finances to enable it to meet rising costs Nor were these the first adjustments to be made For instance, economies involving cuts in the remuneration of dentists, opticians, and chemists had already been made, and patients' travelling expenses to hospitals had been curtailed The Secretary of State for Scotland took a similar view, defending what he described as modest charges on the very periphery of the service

Dr **Santo Jeger**, on the other hand, firmly denounced the new charges They were, he said, deterrents rather than money-raisers They would be a counterblast to health propaganda Spectacles and dentures were not inessentials but an important part of treatment If economies had to be made, could not old spectacle frames be used? Could not the patient be asked to provide his own bottle for his medicine? What about further adjustments of dental fees? Were not the sums paid to medical specialists rather inflated compared with those to other members of the medical profession? Dr **Charles Hill** joined Dr Jeger in the defence of dentures and spectacles He deprecated any suggestion that the word cosmetic should be applied to them, for they were of real importance to health On the other hand he accepted the need to fix a ceiling for our health service if other less glamorous but also important social services were not to suffer But an over-all ceiling should also mean a series of ceilings within the service for the component parts At present hospitals claimed two-thirds of the health service expenditure, and if this went on other parts of the service would have to be cut He thought there was insufficient control and economy in the hospital service and that this could only be remedied by allocating money at the lowest possible administrative level But though he agreed that charges must be made he regretted that they had been slapped on at administratively convenient points without consideration of their effect on health Thus two large obvious items had been chosen to bear the brunt It was true that until we had more dentists to safeguard our children's teeth, we must place a financial barrier between the public and the dental service But why place it four-square on the dental plate? Turning to the ophthalmic service he reminded the House that nominally its present form was temporary He thought the best way to control it was to bring it as originally planned, under the ægis of the hospitals.

[1] Corporation of Glasgow Education Health Service Report on the Medical Inspection and Treatment of School Children for the Year ended July 31 1950

[2] *East Anglian Times* April 19, 1951 p 5

Paying for Beds

On the motion for the adjournment on April 24, Brigadier J G SMYTH raised the question of pay beds in hospital, basing his remarks on the experience of one of his constituents

This constituent Mr Harris, had an income of £500–£600. Last August his wife was taken seriously ill and her general practitioner diagnosed an irreducible femoral hernia strangulation. The doctor had asked King s College Hospital, where Mrs. Harris had some years before been a patient if they had any public beds free, but they had none The doctor then suggested she should inquire if there were any private or semi private beds available she rang the hospital again and found there were The doctor warned Mr Harris that the fees would be about 13 or 14 guineas for the bed and that there would also be a surgeon s fee but Mr Harris maintains he was given no indication what the surgeon s fee would be He admits that he signed a form but he did not know what was written on it at that moment his wife was so ill he would have signed anything When Mrs Harris left hospital her husband was given a bill for £85—14 days in hospital at 12 guineas a week, surgeon s fee of £52 10*s* anæsthetist s fee of £7 7*s* Mr Harris was unwilling to pay, but both the hospital and the surgeon threatened to bring legal proceedings and after some months the account was settled

Brigadier Smyth felt that there should be a distinction between a patient who arranged for an operation in a private ward beforehand and knew what he was letting himself in for, and someone who was desperately and suddenly ill He felt there should be more give and take

Mr ARTHUR BLENKINSOP, parliamentary secretary to the Ministry of Health, said that the case raised an important principle for which he had much sympathy, it also raised problems which the Ministry had been trying to meet for some time There was a proviso in the Act that pay beds may be used without charge where there was urgent medical need, and during the last six months King s College Hospital had admitted 65 cases free to pay-bed accommodation. The proportion of pay bed as against free-bed accommodation was under discussion and he understood that before long a further 30 beds at King s would change over from pay-bed to amenity or free-bed accommodation In cases of this kind the normal procedure was for the practitioner to let the hospital know when no ordinary accommodation was available that the case should be regarded as an emergency He was satisfied that in this case the hospital did not understand the case was an emergency It was true that there was no general bed available at King s, but there might have been one in a nearby hospital—the Dulwich Hospital The service could not guarantee that admission can be made automatically to any particular hospital Occasionally it was found that admission had been made to a pay bed through misunderstanding, adjustments were then made later at a time when the anxiety was not so great Mr Harris was presented with his account at the end of the first week but he made no complaint and let it run on. Definite pledges had been given to the medical profession, Mr Blenkinsop pointed out that there should be some pay bed accommodation and as long as there was surely it was reasonable to try to ensure that it was put to the best use for the purposes for which it was intended, except under emergency conditions

QUESTION TIME

Health Centres and Group Practices

Mr SOMERVILLE HASTINGS asked the Minister of Health how many comprehensive health centres had been provided since 1948 how many were now under construction either by new building or adaptation, how many centres for group practice had been provided since July, 1948, how many were now under construction either by new building or adaptation.—Mr H. A. MARQUAND replied Nine premises taken over when the National Health Service began are being administered as health centres for groups of doctors and other services One large centre is under construction, and tenders for two smaller ones have been invited.

Mr HASTINGS Would the Minister not regard it as dangerous if when the time came to make it possible to build health centres and centres for group practice, there was no more experience of them than is suggested as possible in his answer?—Mr MARQUAND I have every sympathy with this and I intend to encourage where suitable conditions are available the establishment of further group centres of this kind

Mr HASTINGS asked the Minister why he had refused the London County Council permission to provide at the Hampstead Health Institute a centre for group practice, and how far it was now his policy only to permit local authorities to make provision for group practice in under-doctored areas. —Mr MARQUAND replied In general I want to see some experiments in provision for group practice in suitable areas, but this area is already well supplied with doctors and surgeries Two centres are out to tender at the moment—one in Bristol and one in Farringdon Other proposals are under consideration. In Hampstead it is understood that the group of doctors wishing to practise at the centre intended to continue their existing practice at their own private surgeries and to seek new patients for their practice at the health centre

Hospital Accommodation

In answer to a question Mr MARQUAND stated that the total number of staffed beds in hospitals now in the National Health Service was 440,231 on June 30, 1948, and 458,363 on Dec 31, 1950

Of these about 6875 were pay beds or 1½% of the total number of staffed beds which were set aside at present under section 5 of the National Health Service Act 1946

Unsuitable Hearing-aids

SIR THOMAS MOORE asked the Minister how many National Health hearing aids had been returned by their recipients as unsuitable—Mr MARQUAND replied Precise figures are not available but the number is estimated at 2000

National Health Service Spectacles and Dentures

Mr GORONWY ROBERTS asked the Minister the number of persons issued with free spectacles and dentures in the years 1948 1949, and 1950 respectively—Mr. MARQUAND replied Precise information is not available but I estimate that in England and Wales the numbers of dentures and spectacles supplied (including those for which the patient paid a contribution) were approximately as follows

	Patients supplied with dentures	*No of pairs of spectacles*
1948	200,000	1 500 000
1949	2,300 000	7 250 000
1950	3 450 000	8 250 000
	5 950 000	17 000 000

Qualifications of Foreign Dentists

Mr S S AWBERY asked the Minister what steps were now being taken to utilise the services of experienced foreign dentists in this country who had been naturalised what discussions had taken place with the Dental Board on this subject and with what result—Mr MARQUAND replied The Government intend at a convenient opportunity to introduce a Bill which will include proposals for new methods of assessing the qualifications of foreign trained dentists I am satisfied that all that can be done under the existing law has been done

Replying to further questions Mr MARQUAND said that the number of dentists affected was a good deal fewer than 100 It was not possible to allocate to the school dental service personnel who were not qualified to practise dentistry under the law

Durham County Council

Miss IRENE WARD asked the Prime Minister whether, in view of the Durham County Council's decision to cease questioning teachers as to whether they are members of their appropriate unions, he would now take steps to ensure the adoption of a similar attitude with regard to other employees of the council —Mr CHUTER EDE replied the Prime Minister has no information that similar questions are put to other employees, but Ministers are concerned to intervene in the actions of local authorities only where these actions may endanger the efficiency of services for which the Ministers have responsibility

Accommodation for Mental Defectives

In answer to a question Mr MARQUAND stated that according to returns made by local health authorities on Jan 1, 1951, there were 5316 mental defectives awaiting admission to institutions There was no reason to think that the proportion of mental defectives was increasing, but the number increased yearly with the population Provision for these patients received high priority in the hospital service, within the limits of capital investment and staff available

In a written answer the Secretary of State for Scotland stated that 1200 names were on the waiting lists of mental defective institutions in Scotland

Boarding-out

Major NIALL MACPHERSON asked the Secretary of State for Scotland how many lunatics were boarded out in the year ending March 31, 1950, and how this figure compared with the number for the two previous years —Mr HECTOR McNEIL replied 49 lunatics were boarded out during the year ending March 31, 1950 (27 males and 22 females) The numbers boarded out during the years ending March 31, 1949, and March 31, 1948, were 32 (19 males and 13 females) and 29 (15 males and 14 females) respectively

Major MACPHERSON Under what conditions are lunatics boarded out and what supervision is exercised ?—Mr McNEIL Lunatics are boarded out either with their own relatives or with unrelated guardians For lunatics boarded out with unrelated guardians the aim is to provide a home life in suitable surroundings, men are usually placed on small farms or crofts and women in cottages in villages Not more than four patients can be placed with any one guardian The homes are usually found by the local health authority, and the sanction of the General Board of Control must be obtained to the placing of any patient with the guardian selected The board exercise supervision over the patients, who are visited at least once a year, and oftener in special circumstances, by a deputy medical commissioner In addition the patient is visited four times a year by a doctor, and twice a year by the local authority welfare officer acting on behalf of the regional hospital board

Brussels Treaty Public Health Committee

Mr BARNETT JANNER asked the Secretary of State for Foreign Affairs what were the present purposes and terms of reference of the Brussels Treaty Public Health Committee, what was its composition, who were the representatives of Great Britain thereon, what were the main subjects of the committee's recent session at Marseilles, and what were the major recommendations of this committee which had been implemented up to date —Mr K G YOUNGER, Minister of State for Foreign Affairs, replied This is one of several committees set up to consider the development on corresponding lines of the social services of the five countries, in accordance with Article II of the Brussels Treaty Its members are administrative and medical officers of the health administrations of the five countries At the meeting to which my hon friend refers the committee discussed the control of foodstuffs and proprietary medicines and the protection of populations from the health point of view in war time The main recommendations of this committee to have been put into effect so far are those for treating the five countries as a single territory for the health control of sea and air traffic

Dentures and Spectacles for Servicemen

In answer to a question Mr JOHN STRACHEY, Minister of War, said that the question whether soldiers were affected by the new proposals for payment for dentures and spectacles was under consideration

"When we have thousands and thousands of pounds in the bank" I said to my wife as we lay in bed on Sunday morning, "I shall have breakfast in bed every day with little triangles of thin toast and two sorts of marmalade And somebody will say 'Will you have tea or coffee this morning?' without adding 'because we've run out of coffee.' And we shall say 'Shall we go to Bermuda *again* this winter and we shall live the Gracious Life, like the advertisements" I was dragged back from the Ambassador's reception by our First Child's insistent "Daddy! Daddy! Daddy!" "Yes, First Child?" "Why were you in the coffee?" "In the coffee? What do you mean?" "You said you came out of the coffee" "I said we *ran* out of coffee That's different It means we didn't have any Look, First Child, go and help your sister put her dolly to bed" A moment later piercing screams indicated that Second Child had been inconvenienced in some way "What's the matter now?" "First Child touched my baby!" A crash, followed by tinkling of glass and bellowings, took me out of bed and down the stairs At the bottom I kicked the remains of my shaving mirror into a corner picked up Third Child and mopped up the blood 'And our puppy," I said, as I went back into the bedroom, 'will be *thoroughly* house-trained" I threw my slippers out of the window "By then he will be a graceful Borzoi," I added, throwing the laws of genetics after them, "and you, my dear, shall stand on the terrace with your fingers resting lightly on his head" "Oh *do* get up, Daddy," said First Child "No," I said, "it's only seven o'clock and it's Sunday morning" "But it's *quite light*," said First Child indignantly I put my head under the bedclothes "You'd better get up," said my wife unfeelingly, "and do something towards putting those thousands and *thousands of* pounds in the bank" Well, here it is

As Lady Bracknell said so memorably, "To lose one parent may be a misfortune to lose both looks like carelessness" But my recent experience with the R N and R M Recruiting Headquarters suggests that to lose not only one's parents but one's entire family and forebears is sometimes a patriotic duty Their letter ran

> 'You have been found Temporarily Medically Unfit for entry into the Royal Navy/Marines as a volunteer due to —
> Family history of T B
>
> Should you still wish to be considered as a candidate for the Royal Navy/Marines you should visit your own Doctor and endeavour to have this defect remedied

The doctor, I suppose, will do the job for a small *decapitation fee*

* * *

Well, I finished my wool rug and, against my better judgment, was persuaded to enter it in the local Arts and Crafts Exhibition, where it was awarded a "Highly Commended." This damning with faint praise might have been weathered had not my daughter—in another class, it is true—taken a 'First" This has led to the discharge of numerous shafts of juvenile wit and been wholly subversive of parental discipline Most humiliating Let other non surgically-fingered fathers take warning and avoid vulgar competition with their offspring No good can come of it

* * *

Our latest technique with flies in the operating theatre is simple, effective, and cheap Induction is preferably by the anæsthetist, who fills a 10 ml syringe with ether and stands at the ready Spotters report on the whereabouts of the fly, hissing and pointing as soon as it settles The anæsthetist takes aim and, after allowing a little for gravity, smartly rams home the plunger of the syringe If the resultant jet lands within a foot of the fly, it drops to the floor in coma. The rest can be left to Sister The range can be anything up to 15 ft and the trajectory should avoid the surgeon.

Letters to the Editor

PSYCHIATRY AND THE LAW

SIR,—The nation wide publicity given in the press to the advice of the Lord Chief Justice, Lord Goddard, when he addressed the annual conference of the National Association of Probation Officers on April 20, and warned them against "the fashionable craze for sending children to psychiatrists" and urged more frequent punishment for young offenders, is only the most recent example of the avidity with which our newspapers blazon abroad the opinion of any authority who demands a return to such punitive measures as the birch or flogging

Editors and their newspapers live by "giving the public what it wants," and their shrewd choice of this sort of subject reflects our uneasy social conscience We are all relieved when we read that Lord So and so or Mr S Snooks, J P, regards the juvenile delinquent either as just a naughty boy (negligible) or as a precocious monster (alien) In either case, we need concern ourselves no more with the young rascal—let him be punished His punishment gives us respectable citizens an opportunity for revenge, and makes us still more aware of the gulf separating him from ourselves

The average man who says "I was well and truly thrashed by my father (or schoolmaster) and it did me the world of good" quite forgets that it did him good because he himself accepted the values held by the chastiser or by the society he represented But the delinquent, whose whole attitude to society is conditioned by early separation or lack of emotional support from his parents, has no such inner assent His attitude to punishment can only be visualised in terms of a prisoner-of war resisting and resenting the stern measures of his captors they may cow him into submission but they can never win him to allegiance

Society's best protection against the offender is so to win him It is only by understanding and accepting our own antisocial tendencies—not ensconcing ourselves on judicial benches, in editorial offices, or psychiatrists' consulting rooms—that we can give the delinquent the understanding and acceptance he needs, so that he can accept us and our values and become our fellow citizen

London W 1 F R C CASSON

COMBINED ABDOMINO-VAGINAL HYSTERECTOMY

SIR,—I was interested in Mr Ellsworth Laing's suggestion last week that the cavity left after removal of the vagina should be treated by Thiersch grafting after the fashion of Sir Archibald McIndoe I have not actually done this as a primary procedure at the time of the operation, but there is one candidate for it as a secondary procedure She is aged 29, and it is 16 months since her operation, which included total cystectomy and implantation of the ureters I felt that a decent interval should elapse and that the prognosis should be fairly assessed before submitting her to further surgery Mr Laing will therefore realise that in one case his suggestion will probably be adopted, but as a secondary operation

I am not so sure about the advisability of primary grafting, for the following reasons (1) the operation has already been considerable, and any further elaboration of it may be detrimental to the patient, (2) the cavity left by the removal of the vagina is bounded anteriorly by the bladder, posteriorly by the rectum, and laterally by a vague space from which the paravaginal tissues and the cardinal ligaments have been removed The ureters are superolateral relations of this space, and the peritoneum of the newly formed pelvis makes the roof The bladder and the rectum may to some extent have been damaged, and I should be a little hesitant to add the trauma produced by the pressure of a mould to these tender structures For example, the ureters have been denuded of their distal blood supply by the dissection and in about 5% of cases undergo avascular necrosis, so that any further insult to their blood supply is to be avoided I should say that the optimum time to apply the mould and the graft would be 2–3 weeks after the operation, when the cavity and its visceral boundaries are already protected with early granulations

One final point must be made Mr Laing slightly exaggerated by suggestion the inconvenience caused by the slow healing of the cavity In some of my most favourable cases this has been clinically complete in 4 weeks and has never caused the patient any inconvenience whatsoever It was only in the case mentioned above, where the uterus, vagina, and bladder were removed, that the cavity took 6 months to heal Perhaps the situation can best be summarised by saying that if the case goes well the cavity causes little or no trouble If it is slow to heal and the cause of this is not recurrent or unextirpated growth, then I think Mr Laing's suggestion of grafting should be considered In the young patient for whom vaginal function is important, secondary grafting by McIndoe's operation should be employed when the prognosis is reasonable—say, 18 months to 2 years after the primary operation

London W 1 JOHN HOWKINS

EMPYEMA THORACIS TREATED WITH PENICILLIN AND ASPIRATION ONLY

SIR,—We were interested to see that the experience of Dr Asher and Dr Davies, recorded in their paper last week, bears out our own experience of the efficacy of this treatment which we reported in a rather larger series of cases [1] The technique they employ is similar to ours except that the need to inject intrapleural penicillin in a large volume of fluid is not mentioned We regard this as an important practical point since penicillin does not mix readily with purulent exudates It should, therefore, be given intrapleurally in not less than 20 ml of normal saline

EPILEPTIFORM FITS DURING CALCIFEROL THERAPY

SIR,—The article by Dr Beare and Dr Millar (April 21) implies that calciferol has been the cause of epileptiform fits , but in two cases reported in this article the evidence does not seem adequate

Case 2 is of a woman, aged 20, admitted on Feb 21 in status epilepticus Later it transpired that she had been treated with 'Sterogyl' 600,000 units orally on Feb 14 and again on the day of admission." Only in the last line are we told that "the patient's mother suffers from epilepsy" Two lines above, they say no cause except calciferol intoxication was found for the fits'

Two doses of 600,000 units pure calciferol at a week's interval have not, up till now, been shown to be capable of intoxicating an adult A blood calcium level of 14 mg per 100 ml is not a sign of intoxication at all , and vomiting, pain in the jaws, and colicky pains in the abdomen can occur without calciferol therapy

Case 1 concerns a man, aged 20, who, apparently for the first time, had one epileptiform attack on two consecutive days *As this accident occurred after* taking more than 42 million units calciferol, "severe calciferol intoxication was provisionally diagnosed" It is surprising, to say the least, that the patient tolerated 150,000 units daily for 9½ months and that the drug should then suddenly have a convulsant effect Epileptiform attacks certainly occur for the first time in adults who have never taken calciferol As regards the slight albuminuria, which cleared up completely in 9 days and recurred occasionally some months later when the patient was no longer under calciferol treatment, it would appear difficult to link the drug with possible renal impairment, but Dr Beare and Dr Millar suggest this connection repeatedly, and do not deny it anywhere In addition, "the state of renal function before calciferol was given is not known"

In conclusion, there does not seem to be adequate evidence that calciferol produces epileptiform fits either in non epileptic or in epileptic subjects

ACCOMMODATION FOR MEDICAL STAFF IN HOSPITALS

SIR,—I was so interested in Dr Goodall's remarks (April 14) about the desirability of providing married quarters for hospital residents that I am tempted to record my own experience

Recently I was resident at a famous hospital in the Home Counties My self contained accommodation consisted of two bedrooms, a bathroom kitchen, and a living room When built during the war it was occupied by a doctor and his wife Having been separated once and, as a Reserve officer, likely to be again, I applied for permission for my wife to stay in the unoccupied room for limited periods during my term of office This request was refused without adequate reason, the impression being conveyed that the demand was outrageous and should not be mentioned again

It is to be hoped then that Dr Goodall's work will not only stimulate the creation of married quarters for residents, but also change the outlook of management committees and administrators towards the use of existing resources

London W C 1 F G HARDMAN

HYPERCALCÆMIC URÆMIA WITH NEPHROCALCINOSIS

SIR,—I read with interest the report (April 21) by Dr Fulton and Dr Paget, as I have seen a similar case

A 62 year old housewife was admitted to hospital on Oct 4, 1946 For the previous month she had been confined to bed with increasing weakness and abdominal pain She complained of aching pains in her limbs and persistent pain across the upper abdomen She had troublesome vomiting and diarrhœa, and was thirsty She was drowsy and her skin had a muddy appearance Her tongue was dry and covered with a brown fur, and her breath had a slightly urinous odour There was no abnormality in the heart and lungs, and the blood pressure was 170/80 mm Hg The abdomen was slightly distended and appeared to be tender all over No œdema was found

Investigations—Blood Hb 80% (Haldane), red cells, 4 460,000 per c mm , mean corpuscular diameter 7 6 μ, white cells 10,000 per c mm (neutrophils 53%, metamyelocytes 1%, lymphocytes 40%, monocytes 6%) Urine specific gravity 1010, slight trace of albumin and a few hyalogranular casts and pus cells no Bence Jones protein Blood urea 108 mg per 100 ml blood calcium 16 8 mg per 100 ml , blood phosphorus 2 7 mg per 100 ml , serum alkaline phosphatase 30 units The total serum protein was 5 75 g per 100 ml of which 3 24 g was albumin and 2 51 g was globulin. The erythrocyte sedimentation rate was 9 mm in the 1st hour

A *straight radiograph* of the abdomen did not show any renal calcification and a cholecystogram was normal *Secondary* deposits in the form of circumscribed areas of bone absorption were seen in the ribs, pelvis, spine, scapula and femora A biopsy specimen was obtained from the ilium by trephining and showed secondary deposits, probably from a hypernephroma

Progress—The patient's condition gradually deteriorated, and vomiting and dehydration increased She became

---

1 Elliott W A Young B A *Post-grad med J* 1948 24 175

restless and noisy, and died on Oct. 31. Unfortunately permission for necropsy could not be obtained.

Despite the objection raised by Dr. McGowan last week, the lesson from these case histories surely is that hypercalcæmia and renal impairment should, in the absence of a history of vitamin D therapy, initiate a search for bone secondaries as well as for myelomatosis and hyperparathyroidism.

Grays, Essex. R. N. HERSON.

THE BODY'S IRON

SIR,—The reference in your leading article of April 14 to the case of iron encephalopathy described by Dr. Till and myself[1] is, I think, misleading. It does not mention that the preparation used was different from those previously injected although it was accepted at the time as their equivalent. The total dose was low, and its damaging effect may have been due to the fact that it was "home-made" and not prepared strictly in the same way as other solutions known to be safe.

Enfield, Middx. C. ALLAN BIRCH.

INTER-INNOMINO-ABDOMINAL AMPUTATION

SIR,—I make no apology for describing the following single example of the above operation.

Six months before admission the patient, a boy aged 17 years, fell off his bicycle and injured his right hip. Ten days later he became unable to walk, and the upper part of his right thigh began to swell. He was put into plaster, which, as the swelling increased, had to be removed. The presence of malignant disease was now obvious, and he was left to his fate.

On admission the patient had a huge semi-fluctuating swelling with distended veins involving the upper right thigh and encroaching on the symphysis. The circumference at the groin was 76 cm., compared with 35 cm. on the normal side. Radiographs showed that 14 cm. of the shaft and neck of the femur had been replaced by growth, and spicules of bone could be seen invading the soft tissues up to the pubis; only the shell of the head of the femur remained intact. The lung fields were clear, but the liver and spleen were palpable.

Three weeks were spent, or rather wasted, in applying radiotherapy, getting the patient into suitable condition, and persuading the relatives that an operation offered the only hope. Throughout this time he had a hectic fever and was obviously going rapidly downhill. On admission his red blood cells numbered 3,400,000 per c.mm., and the hæmoglobin was 11·5 g. per 100 ml.; ten days later the figures had fallen to 2,315,000 and 10. Finally 2·5 litres of blood was collected and operation was undertaken.

Anæsthesia was by rectal ether, intrathecal procaine, and closed-circuit oxygen and ether. During the operation 500 ml. of glucose solution was infused intravenously, followed by the 2·5 litres of blood. The operation took 3 hours 50 minutes. Owing to invasion by the tumour along Poupart's ligament, the external iliac artery was ligated at its origin, after stripping back the peritoneum. Thereafter there was no appreciable hæmorrhage until the guide for the Gigli saw was being introduced through the sciatic notch. The hæmorrhage from the gluteal muscles was then easily controlled by digital pressure on the common iliac artery. The skin flap was dissected back at the last possible moment. The external iliac vein was ligated just before removal of the limb. The portion removed weighed 16 kg. (the patient's weight before operation was 51 kg.). Histological examination showed that the growth was an osteosarcoma.

In the three weeks since operation the patient has gained 2 kg. in weight, his temperature has fallen to normal, his appetite has become ravenous, and he is already walking with crutches.

In such a case this formidable operation is amply justified. I am grateful to my former teacher, Sir Gordon Gordon-Taylor, who has done more than anyone else to bring this procedure within the realm of the feasible and the humane.

Altounyan Hospital, Aleppo,
Syria. E. H. R. ALTOUNYAN.

MANAGEMENT OF FLEXION DEFORMITIES IN ARTHRITIS

SIR,—One of the problems facing those who have to care for patients with chronic arthritis is the treatment of flexion deformities, which are caused by increased tone of the flexor muscles and wasting of the opposed extensor muscles. In the last few years we have treated nine bedridden arthritic patients with flexion deformities of the legs with combined physical and medical treatment, and all can now walk. Five have been discharged from hospital, either to their homes or to a hostel where there is no nursing care. The methods of treatment used are recorded so that others interested in this problem can use them and perhaps improve on them.

It was assumed that the primary cause of the flexion deformity in these patients was joint pain, and every effort was made to relieve this. Pain can arise from inside the joint, from the capsule, or from the periarticular tissues, and injection of a local anæsthetic into the site of origin gave relief for periods varying from two hours to five days. For intra-articular injection procaine with lactic acid was used; for other sites, procaine alone. Injections were given once a week, but more often if severe pain recurred. The patients had spasm of the hamstrings and adductor muscles which caused pain when the knee was extended. Tender spots were often present in the muscle bellies, and when these were anæsthetised extension became less painful. At first these spots were injected with procaine but later we used neostigmine ('Prostigmin') 0·5 mg. with better effect.

The injections when used in conjunction with physiotherapy stopped the pain in some patients, but others needed tab. codein. co. once or twice a day in addition. If the tender spots were in the superficial tissues, 1% ephedrine cream, rubbed in thoroughly daily, was effective. The combination of local anæsthetic, neostigmine, and ephedrine cream has given more relief than any other medical treatment in our experience.

Before starting physiotherapy neostigmine 0·5 mg. was injected to produce muscular relaxation, and a posterior plaster was then applied to the limb in extension. This plaster was worn during rest and at night, and a new one applied when necessary. The affected joint was then treated with short-wave diathermy or infra-red rays. When a painful spot in the soft tissues resisted other treatments, ionisation with histamine was often successful. The patient was not allowed to walk until the quadriceps had been strengthened, and this was achieved by a combination of faradism and active exercises. The exercises were carried out in general classes and also individually in the Guthrie Smith frame with slings and springs. Neostigmine was always given beforehand, as it allowed more freedom of movement during exercise. Extension and abduction of the limbs were encouraged, but flexion and adduction movements were reduced to a minimum. When the local pain diminished the joints were passively stretched, after a preliminary injection of neostigmine, by a sling loaded with a 6 lb. weight applied for ten minutes. For greater effect the feet were kept at the same level as the body. Gradually the weight and the time of application were increased up to 12 lb. for thirty minutes. The patients were also made to lie prone and practise straight-leg lifting and knee extension.

In some patients the patella was adherent to the lower end of the femur and this prevented full extension. The patella was mobilised where possible by manipulation under local anæsthesia, and, if successful, movement increased and walking became easier. Two patients in whom the patella remained fixed improved sufficiently to be included in this series.

Close cooperation between physician and physiotherapist is essential. It has taken as long as four years of continued treatment to enable some of the bedridden patients to walk, and one woman relapsed three times before she was able to walk in comfort Treatment has failed in four other patients who are excluded from this series Three of these have an additional disease which prevented treatment, and the fourth was psychologically unsuitable for treatment

BILIVERDIN

SIR,—In reference to the letter last November from Dr Gairdner and his colleagues,[1] I wish to point out that biliverdin does not give a positive diazo reaction [2] Statements to the contrary are occasionally made, but such findings are due to the use of impure samples of biliverdin which contain bilirubin

Institute of Medical Research,
Royal North Shore Hospital
Sydney, Australia
R LEMBERG

PARAFFIN IN SYRINGES

SIR,—I read with concern Dr McCartney's statement (March 3) that the syringes supplied ready for use to a group of hospitals are lightly lubricated with liquid paraffin Surely this is quite unnecessary and very dangerous

I do not know whether it has been determined that there is a quantity of paraffin below which none will leave the syringe with an aqueous injection, nor whether those who assemble the syringes can be relied on never to exceed such an amount, but I have seen syringes, used for withdrawing blood samples, containing so much liquid paraffin that had they been employed for intravenous injection embolism would have been almost inevitable However, even small quantities may involve serious risk now that so many injections are of fat solvent substances (e g, oily penicillin), which will certainly dissolve the paraffin and carry it into the tissues On the same grounds, strong objection must be taken to the practice of "sterilising" syringes by rinsing with hot paraffin

It seems ironical that, after the creditably prompt action by doctors which led to legal prohibition of the use of mineral oils for cooking, we should now be injecting the stuff ourselves

Napsbury Hospital, St Albans
A C WOODMANSEY

METHONIUM FOR INTRACTABLE HICCUP

SIR,—Any effective therapy for intractable hiccup is welcome, and for that reason I should like to report briefly a case recently referred to me

A man, aged 76, had suffered from epigastric pain $^1/_2$–1 hour after meals since recovering from influenza one month before On Feb 16, for no obvious reason, hiccup set in and persisted despite treatment, including paraldehyde, morphine, carbon dioxide inhalations, and pressure on the eyeballs Hæmatemesis occurred on Feb 23, and the patient was admitted to hospital the following day In hospital there was no further hæmatemesis, but hiccup continued Routine clinical examination failed to reveal any abnormality to account for this distressing symptom

On Feb 26 treatment with hexamethonium bromide ('Vegolysin') by mouth was begun Two tablets, each containing 0 25 g of hexamethonium bromide, were given with no result, and four hours later three tablets were given Half an hour later the hiccup stopped completely, there has been no recurrence A subsequent barium meal revealed no abnormality in the gastro intestinal tract, the blood-urea was 42 mg per 100 ml

The ætiology of the hiccup in this case is uncertain, but the effect of hexamethonium bromide was so dramatic and immediate that others may be prompted to test the drug in similar cases

Lymington Hospital Hants
R J MCGILL

ACQUIRED IDIOSYNCRASY TO P A S

SIR,—Several descriptions of acquired allergy to para aminosalicylic acid (P A S) have appeared in your columns,[1,2] but the following case showed certain features that have not been previously described

A young man was admitted to Guy's Hospital on April 15, 1948, with bilateral tuberculous infiltration of the lungs and cavitation at the left apex Examination of the sputum revealed tubercle bacilli Soon after admission a pink, circinate, and slightly raised rash appeared on the anterior aspect of the chest, the upper arms, and the abdomen These lesions faded within forty eight hours but reappeared intermittently throughout the next month They were diagnosed as toxic allergic manifestations—i e, tuberculides

Six weeks after admission a phrenic crush was performed on the left side, and an artificial pneumoperitoneum was induced Two days later treatment with P A S was instituted, the patient receiving a total of 12 g in twenty four hours This dosage was found to maintain a blood level of about 12 mg per 100 ml At this time the erythrocyte sedimentation rate (E S R) was 25 mm, and the patient was apyrexial

On Aug 16, sixteen days after the start of P.A.S and eighteen days after the induction of an artificial pneumoperitoneum, the temperature rose to 100°F, it fell to normal until two days later when it rose again, with the accompaniment of a rigor, to 101°F The patient now complained of colicky pain, first in the mid abdomen and later in the right iliac fossa, which was tender White cells numbered 9000 per c mm The patient had given a history suggestive of attacks of subacute appendicitis, and the appendix was removed This showed submucosal fibrosis but no evidence of acute inflammation

The patient appeared to make a good recovery from the operation, but his temperature continued to swing between 105° and 99°F The total white cell count now was 9700 per c mm, with a normal differential count (eosinophils 2%) Blood culture was sterile, and the E S R—12 mm—was the lowest recorded up till then

On Aug 25, nine days after the onset of pyrexia, the patient complained of tinnitus and of pains in the back and limbs Next day a generalised pink maculopapular rash appeared, and the palpable lymph glands throughout the body were tender and moderately enlarged The total white cell count was 14,000 per c mm (polymorphs 58%, lymphocytes 31%, monocytes 2%, eosinophils 9%) The Wassermann reaction was negative

The administration of P A S was stopped, on the same day the blood level was 5 mg per 100 ml, and four days later nil Urticarial weals now appeared round the original skin lesions, which became confluent and highly irritating until five days later, when they faded leaving a generalised erythema with desquamation During this period excretion of urine was partly suppressed, despite a fluid intake of some 100 oz daily, output fell to below 20 oz and the urine contained a trace of albumin The blood-urea at the end of this period was 46 mg per 100 ml, and the blood pressure was normal

On the eighteenth day of illness, as the rash faded, swellings were noted in the regions of the parotid and submaxillary glands, whose buccal orifices were red, and at the same time angular stomatitis developed Next day the application of a sphygmomanometer cuff to the arm was followed by the appearance of large ecchymoses and many petechial spots over the congested area No spontaneous purpura was detected, but intracutaneous bleeding was initiated by the slightest trauma The white cell count at this time was 38,200 per c mm (polymorphs 42%, lymphocytes 39%, monocytes 5%, eosinophils 14%), platelets numbered 105,000 per c mm, the clotting, bleeding, and prothrombin times were normal, the E S R was 10 mm

Next day (the twentieth) the patient complained of mistiness of vision and diplopia He was found to have right external rectus palsy, and in response to questioning he admitted to having felt numbness and tingling of his feet and fingers during the past three or four days No other neurological signs were discovered, and thrice-daily administration of aneurine hydrochloride 25 mg intramuscularly, nicotinic acid 50 mg, and riboflavine 2 mg, was started

---

[2] Livingstone, R Street, E W *Ibid* Feb 10 1951 p 353

Within two days the patient's temperature had fallen to normal, and in three days the neurological symptoms and signs had cleared By Sept 8 twenty four days from the beginning of symptoms the patient, still apyrexial, was feeling better, the swellings of his salivary glands had subsided, but his blood, with a total white cell count of 13,500 per c.mm , still showed an eosinophilia of 18%, while platelets numbered 100,000 per c.mm Plasma proteins at this time were 6 g per 100 ml with albumin 2 55 g , globulin 3 2 g , and fibrinogen 0 25 g per 100 ml There was thus a reversed albumin/globulin ratio of 0 8 1 On Sept 21 the total white cell count was 19,500 per c mm. with polymorphs 42%, lymphocytes 50%, monocytes 2%, and eosinophils 6% On Oct 2 plasma proteins were 7 7 g per 100 ml with an albumin/globulin ratio of 1 1

By the beginning of October the patient had apparently made a satisfactory recovery from his toxic illness, and he was subsequently transferred for sanatorium treatment

Affections of salivary glands as a result of P.A.S toxæmia have not previously been described, neither have neurological signs, though Heming and Stuart[3] reported a case with photophobia and headache The neurological symptoms and signs in the case described here are difficult to explain Lehmann[4] observed that *guineapigs treated with P.A S developed toxic reactions* including anorexia, wasting, falling out of hair, and "symptoms suggestive of vitamin B deficiency" Feldmann et al.[4] failed, however, to confirm these findings

The blood P A.S level, estimated immediately after the drug had been stopped, was not unduly raised, and although the total dosage before the appearance of symptoms had been only 192 g , its administration was continued for a further nine days This prolongation of treatment may, as Livingstone and Street suggest,[2] have conditioned the severity of the illness

Though jaundice was not a feature of this case, the inverted albumin/globulin ratio of the plasma proteins suggested hepatic damage Finally, the patient received, other than P A S , only anti histamine drugs These were given as soon as the rash appeared, but, apart from allaying the itching of the skin, they did not seem to influence the course of the illness

I wish to thank Dr E R Boland, under whose care this patient was treated, for his advice and for his permission to publish this report

THE ECONOMIC VALUE OF THE DOCTOR

SIR,—In his letter of April 21, Dr Rabson, commenting on Dr Ffrangcon Roberts's article (March 24), points out that "premedical and medical training is now largely technical," with a resultant "personality inadequacy" in the doctor This defect in scientific training is not confined to medicine, and it might be of interest to quote from the foreword to the first number of the *British Journal for the Philosophy of Science* This journal, first published in May, 1950, is the official journal of the Philosophy of Science Group, which concerns itself with "an approach through the various special sciences to the philosophy of science" The foreword says

> "The young student of science has now no leisure to reflect on the meaning of his work. As soon as he has passed through the strenuous undergraduate days he enters a field where the race is to the swift and favour to men of skill who have no *time to become men of understanding* The probable consequences need no emphasis The deep personal problems which the reflective in all generations feel impelled to face become more and more intertwined with the knowledge that science brings and it becomes more and more imperative to understand the meaning of such knowledge and its relation to the religious, ethical æsthetic and other elements of our mental environment The faster knowledge grows and the more deeply it penetrates the more difficult becomes the work of assessing its ultimate significance Only the scientist can do it adequately, and he is becoming less and less capable of his task because the nature of his training and his preoccupation with the exigencies of his immediate calling do not, and are not intended, to fit him for this task"

Philosophical thought in this country has undergone *tremendous changes during the past fifty years—changes* which as yet have made little impact on medicine The sort of "revaluation of the doctor" which Dr Rabson thinks so desirable but so depressingly remote, will have to be based on a revival of the doctor's confidence this can only come when the doctor knows that the philosophical basis of his practice is sound For this to happen, he would be well advised to take into account the linguistic movement which now dominates the philosophy faculties of Oxford, Cambridge, and London Without enlarging on this rather sweeping statement, might I suggest that those who are interested should read A G N Flew's *Logic and Language* (Blackwell) as a general introduction to the subject

UNICELLULAR SEBACEOUS GLANDS

SIR,—The "unicellular sebaceous glands in the basal layer of the normal human epidermis" described by Mr Wolff in your issue of April 21 are dendritic melanoblasts This can be proved by the "dopa" reaction, or *more conveniently by using Masson's silver stain for* melanin, which will blacken the granules already formed in some of the cells

These cells have been known for some time to contain a lipid such a lipid is not uncommonly found in the nævus cells of a benign melanoma In some circumstances melanoblasts produce more lipid than melanin Xanthelasma palpebrarum is merely a benign melanoma in which there is more lipid than melanin production, even so the superficial xanthoma cells may be seen to contain fine grains of melanin This has usually been explained by claiming a histiocyte origin for the xanthoma cells, but I am obtaining material which suggests that the correct explanation is that they are derived from melanoblasts

MIND AND MATTER

SIR,—While reading Dr Russell Brain's delightful address in your issue of April 21, I could not help remembering the words of Whitehead "The safest general characterisation of the European philosophical tradition is that it consists of a series of footnotes to Plato"

For Plato the world is one , but from the point of view of knowledge we have to distinguish a physical aspect, the physical world in which we live and act, and the absolute aspect, the world of ultimate reality That such an ultimate and supreme reality transcending our physical being exists is shown by the consciousness we have of the transcendence of the physical world, by our ideas of good, of value, of God, and of immortality, by our *astonishment before the immensity of the Universe*, and by our intimate feeling of creativity, liberty, and power of choice

Knowledge of the physical world—always, according *to Plato*—is obtained through the perceptual conceptual mechanism, what we call today the scientific method, our "practical reason" bound up with the organisation of our nervous system, developed in the course of evolution to equip us in our struggle for physical life, and thus, although supreme for this particular object, not adapted for knowledge of the ultimate reality, the absolute world Knowledge of this absolute world is based on a different method, the Platonic dialectic, a complicated process of abstract thinking, in which after rubbing together conflicting hypotheses, living in our mind various alternatives, "the truth is brought to patients to walk, and one woman relapsed three times before she was able to walk in comfort Treatment has failed in four other patients who are excluded from this series Three of these have an additional disease which prevented treatment, and the fourth was psychologically unsuitable for treatment

BILIVERDIN

SIR,—In reference to the letter last November from Dr Gairdner and his colleagues,[1] I wish to point out that biliverdin does not give a positive diazo reaction [2] Statements to the contrary are occasionally made, but such findings are due to the use of impure samples of biliverdin which contain bilirubin

PARAFFIN IN SYRINGES

SIR,—I read with concern Dr McCartney's statement (March 3) that the syringes supplied ready for use to a group of hospitals are lightly lubricated with liquid paraffin Surely this is quite unnecessary and very dangerous

I do not know whether it has been determined that there is a quantity of paraffin below which none will leave the syringe with an aqueous injection, nor whether those who assemble the syringes can be relied on never to exceed such an amount, but I have seen syringes, used for withdrawing blood samples, containing so much liquid paraffin that had they been employed for intravenous injection embolism would have been almost inevitable However, even small quantities may involve serious risk now that so many injections are of fat solvent substances (e g, oily penicillin), which will certainly dissolve the paraffin and carry it into the tissues On the same grounds, strong objection must be taken to the practice of "sterilising" syringes by rinsing with hot paraffin

It seems ironical that, after the creditably prompt action by doctors which led to legal prohibition of the use of mineral oils for cooking, we should now be injecting the stuff ourselves

Napsbury Hospital St Albans

METHONIUM FOR INTRACTABLE HICCUP

SIR,—Any effective therapy for intractable hiccup is welcome, and for that reason I should like to report briefly a case recently referred to me

A man, aged 76, had suffered from epigastric pain $^1/_2$–1 hour after meals since recovering from influenza one month before On Feb 16, for no obvious reason, hiccup set in and persisted despite treatment, including paraldehyde, morphine, carbon dioxide inhalations, and pressure on the eyeballs Hæmatemesis occurred on Feb 23, and the patient was admitted to hospital the following day In hospital there was no further hæmatemesis, but hiccup continued Routine clinical examination failed to reveal any abnormality to account for this distressing symptom

On Feb 26 treatment with hexamethonium bromide ('Vegolysin') by mouth was begun Two tablets, each containing 0 25 g of hexamethonium bromide, were given with no result, and four hours later three tablets were given Half an hour later the hiccup stopped completely, there has been no recurrence A subsequent barium meal revealed no abnormality in the gastro intestinal tract, the blood-urea was 42 mg per 100 ml

The ætiology of the hiccup in this case is uncertain, but the effect of hexamethonium bromide was so dramatic and immediate that others may be prompted to test the drug in similar cases

ACQUIRED IDIOSYNCRASY TO P A S

SIR,—Several descriptions of acquired allergy para aminosalicylic acid (P A S) have appeared in yo columns,[1 2] but the following case showed certain featu that have not been previously described

A young man was admitted to Guy's Hospital on April 1948, with bilateral tuberculous infiltration of the lungs a cavitation at the left apex Examination of the sputu revealed tubercle bacilli Soon after admission a pi circinate, and slightly raised rash appeared on the anterio aspect of the chest, the upper arms, and the abdomen Thes lesions faded within forty eight hours but reappeared intermittently throughout the next month They were diagnose as toxic allergic manifestations—i e, tuberculides

Six weeks after admission a phrenic crush was performed on the left side, and an artificial pneumoperitoneum was induced Two days later treatment with P A S was instituted, the patient receiving a total of 12 g in twenty four hours This dosage was found to maintain a blood level of about 12 mg per 100 ml At this time the erythrocyte sedimentation rate (E S R) was 25 mm, and the patient was apyrexial.

On Aug 16, sixteen days after the start of P.A.S and eighteen days after the induction of an artificial pneumoperitoneum, the temperature rose to 100°F, it fell to normal until two days later when it rose again, with the accompaniment of a rigor, to 101°F The patient now complained of colicky pain, first in the mid abdomen and later in the right iliac fossa, which was tender White cells numbered 9000 per c mm The patient had given a history suggestive of attacks of subacute appendicitis, and the appendix was removed This showed submucosal fibrosis but no evidence of acute inflammation

The patient appeared to make a good recovery from the operation, but his temperature continued to swing between 105° and 99°F The total white cell count now was 9700 per c mm, with a normal differential count (eosinophils 2%) Blood culture was sterile, and the E S R—12 mm—was the lowest recorded up till then

On Aug 25, nine days after the onset of pyrexia, the patient complained of tinnitus and of pains in the back and limbs Next day a generalised pink maculopapular rash appeared, and the palpable lymph glands throughout the body were tender and moderately enlarged The total white cell count was 14,000 per c mm (polymorphs 58%, lymphocytes 31%, monocytes 2%, eosinophils 9%) The Wassermann reaction was negative

The administration of P A S was stopped, on the same day the blood level was 5 mg per 100 ml, and four days later nil Urticarial weals now appeared round the original skin lesions, which became confluent and highly irritating until five days later, when they faded leaving a generalised erythema with desquamation During this period excretion of urine was partly suppressed, despite a fluid intake of some 100 oz daily, output fell to below 20 oz and the urine contained a trace of albumin The blood-urea at the end of this period was 46 mg per 100 ml, and the blood pressure was normal

On the eighteenth day of illness, as the rash faded, swellings were noted in the regions of the parotid and submaxillary glands, whose buccal orifices were red, and at the same time angular stomatitis developed Next day the application of a sphygmomanometer cuff to the arm was followed by the appearance of large ecchymoses and many petechial spots over the congested area No spontaneous purpura was detected, but intracutaneous bleeding was initiated by the slightest trauma The white cell count at this time was 38,200 per c mm (polymorphs 42%, lymphocytes 39%, monocytes 5%, eosinophils 14%), platelets numbered 105,000 per c mm, the clotting, bleeding and prothrombin times were normal, the E S R was 10 mm

Next day (the twentieth) the patient complained of mistiness of vision and diplopia He was found to have right external rectus palsy, and in response to questioning he admitted to having felt numbness and tingling of his feet and fingers during the past three or four days. No other neurological signs were discovered, and thrice daily administration of aneurine hydrochloride 25 mg intramuscularly, nicotinic acid 50 mg, and riboflavine 2 mg, was started

ENERAL PRACTITIONER AND CONSULTANT

IR,—I think that in his letter last week Dr Bower missed the point of Dr Robertson's letter (April 14) one suggests that there is a cleavage between the and the consultant in the sense that they are refusing peak to each other, but the fact remains that there very hard and fast line of demarcation between the Many of the very best consultants in Dr Bower's town have reached specialist status from the ranks eneral practice Such a graduation is quite impossible

is good of Dr Bower to state that the medical ability he G P in Southampton is on a high level The level ll not high enough to prescribe an X ray examination

omsey Hampshire T P LALONDE

SYNCOPE DURING INJECTIONS

IR,—I have recently had to give a course of daily avenous calcium injections to a patient who on the two occasions had a syncopal attack when the needle introduced On the third day I decided to time the ulation of the solution, and I asked him to tell me his sation as the injection proceeded He became very rested in this and had no sign of faintness On sub ient occasions he has timed himself, and each time shown no signs of losing consciousness

suggest that in the susceptible subject mental concen ion by timing intravenous injections may prevent yncopal attack and so not prolong "surgery hours"

arrow L P DAVIES

CALLING ALL ATHLETES

IR,—At the request of the Amateur Athletic Associa n, a small committee has been formed to advise and st athletes in their various problems and difficulties, h as the details comprised under "training," the motion and maintenance of fitness the treatment of iries incidental to sport and so on Such assistance, ich has for long been available in the United States l on the Continent, has in this country been contributed y in a comparatively haphazard fashion by a few erested individuals Now for the first time a systematic roach is contemplated

t is clear that widespread cooperation of the profession essential, and I appeal for the help of colleagues oughout the British Isles The aim is to secure the hnical knowledge and professional experience of a siderable number who in their youth were famous letes They will be asked to give occasional advice to athletes in their neighbourhood, and, when convenient, to attend athletic contests In this way no great demands will be made on their time, and they will have the satisfaction of performing a national service and of preserving their contact with athletics under the most advantageous circumstances

Anyone interested is invited to communicate with Dr John Etheridge, of 73, Fitzjohn's Avenue, London, N W 3, who will in due course forward further information

London W 1 ADOLPHE ABRAHAMS

CONGENITAL INDIFFERENCE TO PAIN

SIR,—With reference to the article of April 14 by Dr Farquhar and Dr Sutton, van Rooy has described 2 cases in which painless parturition led to the accidental death of the newborn infants In these 2 women he found a remarkable absence of pain sensitivity in the lower part of the body without other defects

Another case of congenital indifference to pain was seen by me in one of the Japanese "protection" camps. The patient was a 14 year old boy with mongolian idiocy His teeth were grossly carious, and extraction of two proved completely painless Thereafter he begged for further extractions because the experience had been so pleasant His infected skin was covered with boils and phlegmons, when we had to open them without any anæsthetic the same painlessness was evident We could find no other disturbances in the nervous system (tactile and thermal sensations were intact), his level of intelligence was that of a 6 year old child

Hilversum, Holland D P R KEIZER

PENTAMETHONIUM AND SHOCK

SIR,—Increasing experience of pentamethonium induced hypotension during massive surgical procedures appears to show that shock is not encountered when this method is employed Should any substantial volume of blood be lost replacement by transfusion is, of course undertaken This is in accordance with the observation by Freeman et al[1] that totally sympathectomised dogs were resistant to shock It is not clear whether this action of pentamethonium in preventing shock is due to the great reduction of blood loss, or mainly to the abolition of circulatory reflexes (this latter may imply that vasodepressor material[2] is not produced)

Although established shock is at present regarded as a contra indication to the use of pentamethonium, it does appear that the effect of this agent in preventing the development of shock deserves further investigation

POLIOENCEPHALITIS, "ENCEPHALOPATHY," AND POLIOMYELITIS

SIR,—Dr Warren's case report in your issue of Jan 27, entitled Poliomyelitis and Polioencephalitis with Opso clonia Following Appendicectomy, is of considerable interest and bears upon several points I should like to comment only upon the interval of four weeks between onset of poliomyelitis and those findings interpreted as "polioencephalitis"

Clinical relapses of poliomyelitis with an interval as long as four weeks appear to be rare, and the findings in this patient raise the question of an "encephalopathy" rather than polioencephalitis The onset of convulsions, with loss of consciousness, cyanosis, and oscillation of the eyes, four weeks after paralysis is more suggestive of an "encephalopathy," perhaps associated with hyper tension The levels of blood pressure are not mentioned in the report

---

[1] Freeman N E Shaffer S A Schecter A E, Holling H E *J clin Invest* 1938 17, 359

[2] Chambers R Zweifach B W *Amer J Physiol* 1947 150 239

It is becoming increasingly apparent that arterial hypertension when sought is not uncommon in paralytic poliomyelitis. Although ordinarily it is transient, we have observed persisting changes for months associated with "hypertensive encephalopathy"

It has only been in recent years that the sphygmomanometer has pierced the isolation curtain around the patient Apart from paralysis itself, much clinical and environmental investigation remains to be done with *poliomyelitic patients*

Department of Pediatrics
University of Louisville Kentucky　　ALEX J STEIGMAN

PUBLICITY IN CANCER

SIR,—The importance of combating delays in the diagnosis and treatment of malignant disease at all levels from the patient to the hospital is clear The conclusion that by a publicity campaign a dramatic difference could be brought about in cancer results is, however, less certain

A strong case can be made out that with existing diagnostic methods our present methods of treatment are in general, effective only in the biologically less malignant examples of malignant disease A fallacy arises from a looseness in the use of the word "early," which in one place may mean early in point of time and in another early in point of spread of the disease, that the two are not the same is in *practice only too obvious* While therefore not neglecting any way of making present methods of diagnosis and treatment more effective, the real hope must be for an advance in our fundamental knowledge of the malignant process and its control factors

On the immediate practical plane I venture to suggest that more could be achieved by measures directed to strengthening the status and facilities of the general practitioner—as, for example, by providing him with radiodiagnostic and pathological centres—than by any publicity campaign I would, on the other hand have no objection to explaining to any intelligent layman or group of laymen, who wanted to know, the present position of the cancer problem provided that the explanation was true and based on a correct *assessment* of the situation

London W 1　　DAVID H PATEY

AIR TRAVEL

Mrs A Clifford passenger relations officer of British Overseas Airways Corporation, writes

We were very sorry to read in your issue of March 24 that a peripatetic correspondent formed the impression that the sherry served as an aperitif to the meal was inferior to the quality of that supplied in the bar The truth is that the difference is not one of quality but of taste The sherry provided free is a medium one intended to cater for all tastes as far as possible whereas probably he purchased a dry type Because of the limited stocks which can be carried on an aircraft the choice is necessarily limited, but there is no question of one being inferior to the other

It was decided *some time* ago *that* the *corporation* was entitled to a profit on bar sales and bearing in mind that the tots are doubles our prices are considerably less than *those applying elsewhere* It *must also* be remembered that drinks are provided free of charge with meals Linen towels are to be provided on all our aircraft as soon as supplies *are available*

With regard to the facilities at airports we are only too well aware that in certain cases these are below the standard which we would prefer but this is a matter for the various governments concerned and is outside the province of airlines

It is our policy to give as much information as possible to passengers when aircraft are delayed, sometimes, however, when technical problems arise it is difficult for the engineers to gauge exactly how long the work will take, and they hesitate to give a time of departure which for one reason or another may have to be extended or in more *fortunate* circumstances brought forward No doubt the same applies to other airlines.

Obituary

ALBERT RUSKIN COOK

Kt., C.M G, O B.E, B A. Camb, M D, B.Sc Lond

IT is a considerable achievement to walk for three months over 800 miles of African bush, to found a hospital at the end of the trek, to rebuild it three times within 7 years, and to live to see it stand as a widely renowned and active medical centre 54 years later That, in fact, is what Sir Albert Cook did during his long and distinguished life of service which ended at Kampala on April 23

[Church Missionary Society

Born in 1870, he was the son of a doctor and the nephew of a bishop At St Paul's School, at Trinity College, Cambridge, and at St Bartholomew's Hospital, he won prizes, scholarships, and exhibitions at every stage He graduated as M B in the University of London in 1895, and a year later he set out for Uganda, under the auspices of the Church Missionary Society

After an arduous journey on foot through difficult and dangerous country, he arrived at Kampala, where early in 1897 he established the Mengo hospital, a primitive structure of grass and reeds Within a few years this was replaced by a hospital built of wattle and daub, but this was destroyed by lightning in 1904 The buildings of sun dried brick which were then erected stand today, greatly extended and modernised, as a large and efficient hospital centre At first the hospital was something of a family affair, for Cook married the first matron, Miss Katharine Timpson, one of the original band of missionaries who came with him to Uganda, and two years after his arrival he was joined by his brother, Dr Jack Cook, an outstanding surgeon

In two wars Mengo Hospital opened its doors to the wounded It dealt with many casualties from the Sudanese rebellion of 1897, and again in 1914–18 it was the principal base hospital for Uganda, with Captain Albert Cook in command But peace brought opportunity for expansion of Mengo's real work A medical school for African auxiliaries was opened, and later, through the energy of Katharine Cook, the Lady Coryndon maternity training school was founded, and African girls from all over East Africa went to Mengo for training as midwives and nurses Together the Cooks wrote an illustrated handbook of midwifery in the vernacular, and Cook also compiled a medical phrasebook and vocabulary in Luganda

His work was by no means confined to the mission field, for he took an active part in the development of public health measures and of medical services in Uganda, and his advice was continually sought by the government medical department, who appointed him to every important medical board He and his brother were the first to diagnose sleeping sickness in Uganda and were indeed pioneers in many medical measures

It was natural that many honours should be given him After the first war, he was appointed O B.E and he was honoured by the Belgian government with the Order of Leopold In 1922 he was appointed C M G and in 1932 he was knighted In 1928 he received the silver medal of the African Society He retired from active medical work in 1934 The death of his wife four years later was a grievous blow but for many years his wide knowledge, his counsel, and his wisdom were at the disposal of those who required it, and he remained a consultant to the government hospital and a member of a number of boards In 1945 his book *Uganda Memories* was published by the Uganda Society, which he had served as president In 1947, the jubilee year of the foundation of Mengo Hospital, a fund was raised to rebuild the hospital, and the Uganda branch of the B M.A held a three-day interterritorial meeting to honour its founder

"To those of us who were concerned with medical education in East Africa," writes H J O'D B-G, "the Cook tradition was almost symbolic The vast medical library at Mengo, with its detailed records and case-sheets from the earliest days, is a monument to Cook's care and accuracy He was a simple man of simple faith—a missionary in the fullest sense, for he had a mission to fulfil and spared nothing of himself in its fulfilment His own words reveal the nature of that mission 'to attempt to heal the suffering body is much, to carry the water of salvation to thirsty souls is more, but to combine the two is the grandest work a man can have' Thousands of Africans are poorer for his passing, but healthier and happier for the care and wisdom and sympathy which he gave to them"

PAUL JENNER VERRALL

M B Camb, F R.C S

Mr Jenner Verrall, who died on April 22, was orthopædic surgeon to the Royal Free Hospital, and lecturer in orthopædic surgery at the London School of medicine for Women from 1926 to 1945 But he will also be remembered for his great experience of military orthopædic surgery For well over thirty years he was associated with the Ministry of Pensions, at first as orthopædic surgeon at two of their largest hospitals, and for the last ten years or so as orthopædic specialist at the regional offices in London At the beginning of the late war he was a member of the war wounds committee of the Medical Research Council

Born in 1883 at Brighton, the son of the late Sir Thomas Verrall, M R C S, he was educated at Winchester, Trinity College, Cambridge, and St Bartholomew's Hospital In 1908 he qualified, and two years later he took his F R C S The same year he was appointed to the orthopædic department at St Bartholomew's Hospital where he worked as assistant to Mr R C Elmslie In 1915 he volunteered for service with the R A M C, but he was invalided home after a year in Egypt He then became one of the original team of orthopædic surgeons whom Sir Robert Jones chose to help him in the task of organising the special surgical hospitals to deal with the many thousands of wounded whose injuries came under the somewhat elastic designation of "orthopædic" The biggest of these hospitals was set up at Shepherd's Bush, and it was to this hospital that Verrall was attached

After the war his orthopædic colleagues returned one by one to the ever-widening field of civilian orthopædics, but Verrall remained to carry on the work, at first at Shepherd's Bush and then, after 1925, at Queen Mary's (Roehampton) Hospital, to which the Ministry of Pensions had transferred all their surgical work in London Here to his orthopædic work was added the thousands of men with amputations attending the Roehampton limb fitting centre who for some reason or another were having trouble with their stumps Under his influence a close collaboration soon developed between the limb-fitting surgeons and the operating surgical staff, and from this collaboration was built up that body of amputation surgery which is now accepted practice Not only had the existing amputation cases to be dealt with, but many primary amputations had to be carried out, and on very unpromising material—for example, on limbs with chronic bone sinuses of many years' duration or with unrecovered nerve lesions Those were the days before the sulphonamide drugs or the antibiotics, and it speaks volumes for the high standard of Verrall's work at Roehampton that so few cases went wrong

Shortly after the outbreak of the second world war he gave up hospital work at Roehampton, and as orthopædic specialist to the Ministry in London examined and advised on many thousands of cases both from the 1914–18 war and the 1939 war One of his colleagues writes "His reports were always a pleasure to read—short and to the point, nothing of importance left out, no redundancies, answers given to all questions put to him, and a sound opinion expressed It is perhaps unfortunate that Verrall wrote so little of that branch of surgery on which he could have spoken with so much knowledge and authority, but those who knew him and worked with him can testify to the readiness which he always showed in passing on to others who went to him for guidance something from his own wide experience His work for the Ministry of Pensions continued uninterruptedly until the illness from which he died"

In 1908 Mr Verrall married Edmée, daughter of Comte Lostie de Kerhor de St. Hippolyte She survives him with their only daughter

EUSTACE JOHN PARKE OLIVE

O.B E, M.A, M D Camb, F R C.S

Dr E J P Olive, consulting physician to the Warneford Hospital, Leamington, died on April 14 at the age of 88

From St John's College, Cambridge, he entered St Bartholomew's Hospital, where he had a distinguished student career After qualifying in 1889 he held house appointments at Barts before he migrated to the General Hospital, Birmingham, where he was house-surgeon to Gilbert Barling Thence he went to Leamington, where he was appointed to the staff of the Warneford Hospital, and he spent his long life of professional service in that town In 1892 he took the F R C S, and two years later his M D

He was appointed O B E at the end of the first world war A colleague writes "During both wars Olive was actively employed, and at the end of hostilities he retired and well deserved the honour which was accorded him He was always ready for emergency work, and in his later years he equipped himself as a very competent anæsthetist In a full and valuable life he earned the gratitude of many"

Notes and News

TREE OF HIPPOCRATES

A HISTORIC ceremony took place in the Chelsea Physic Garden on April 27 when a gift from the Greek government and the University of Athens was presented to the Royal College of Physicians of London The gift was a cutting from the famous plane tree of Cos under which Hippocrates is reputed to have taught and it was presented by Dr Gerasime Loverdos, endocrinologist and medical historian, in the presence of the Greek Ambassador, the chairman of the British Council the master of the Society of Apothecaries, the chairman of the board of trustees of the Physic Garden, and representatives of the Royal Colleges Dr W S C Copeman, accepting the gift on behalf of the Royal College of Physicians, said that the cutting would be a living memento of the great Greek teacher to whom modern medicine all over the world owes all that is sound in its origins, and would symbolise for future generations the traditional good will between Greece and Great Britain. Dr Loverdos was also thanked by Mr Walter Prideaux chairman of the board of trustees of the Physic Garden, and by Dr F D Howitt, master of the Society of Apothecaries The tree was planted by Dr Loverdos, Lord Webb-Johnson, Dr Copeman, and Dr Howitt

A second cutting has since been planted in the council garden at B M A House, in the presence of the president and council of the British Medical Association, and a third at Oxford

A UFAW JUBILEE

ON April 30, Major C W Hume, with twenty five years of animal welfare work to his credit, sat down to dine with the friends of the Universities Federation for Animal Welfare, to celebrate this pleasant jubilee Fougasse the dearly loved artist of UFAW, and in other manifestations Mr Kenneth Bird, and editor of *Punch*, was at the head of the table in this family party and toasted The Guests as wittily as he draws Mr W R Wooldridge PH.D, proposing the toast of UFAW, recalled its founding as ULAWS (the University of London Animal Welfare Society) in the days when Major Hume played hockey furiously for Birkbeck College and was tough with his opponents though tender with rats Funds were small in those days and new ideas Dr Wooldridge complained do not come easily to an educated community Major Hume won the university over brought in the veterinarians and invited the late Sir Frederick Hobday to become the first president In replying Major Hume noted that nearly half of the early supporters were present, and he mentioned others who would have been present if they could UFAW attracts people he said because of the sound underlying idea that science and learning have a duty to the subject of animal welfare It also attracts because as Mr John S Cripps said in replying for the guests it sees the problem whole and without undue sentiment All its friends wish it long life and more power to its elbow

CALL-UP OF AMERICAN DOCTORS

BECAUSE of the shortage of volunteers for the American army and air force the Department of Defence has announced [1] that compulsory call up of doctors will begin in July this year The department intends to call up 1202 doctors during July August, and September, but this figure may be reduced if the number of volunteers increases before then. As announced previously,[2] doctors will be selected from those who were trained at government expense in the late war and who served less than 90 days on active service, later additional doctors will be selected from those government trained doctors who served less than 21 months

Conference on A C T H

A conference on A C T H is to be held by Armour Laboratories in Harrogate on Sept 13 and 14 Medical speakers from this country will include Dr W S C Copeman and Dr O A. Savage, Dr, J J R Duthie, Dr J R Forbes, Dr F Dudley Hart, Dr G Kersley, Dr F T G Prunty, and Prof L J Witts Attendance will be confined to those doctors who have administered 'Acthar'

International Centre for Training in Anæsthesia

On April 27, ceremonies at the University of Copenhagen marked the successful conclusion of the initial course at the W H O international training centre for anæsthesiology, established a year ago by W H O and the university A second group of 30 medical fellows—from Finland, Greece, Norway, Sweden, France, Yugoslavia, and Denmark—arrive in Copenhagen this week for the second course of one year W H O provides for the maintenance and travel of the foreign medical fellows, and book allowances for the Danish students, it has also provided anæsthesia equipment

Society for General Microbiology

The following have been appointed as officers and committee for 1951–52

President Prof J W McLeod F R S, meetings secretary W E van Heyningen, general secretary J G Davis, treasurer, R. Lovell editors, B C J G Knight and A F B Standfast associate editors, G C Ainsworth W B Brierley, T Gibson, A T R. Mattick, A A Miles, K. M Smith, A W Stableforth, and D D Woods members of committee L A Allen, C H Andrewes, P W Brian H J Bunker, A W Downie, Betty Hobbs H B Maitland, N W Pirie, H Proom P M Frances Shattock and G Sykes, representing International Association of Microbiologists Sir Alexander Fleming, F R.S

The society, which was founded in 1945, now has 985 members and will hold its September meeting at Manchester Further information may be had from the general secretary, 35, Villiers Road, Southall, Middlesex

Kingston Victoria Hospital

The Ministry of Health announces that the Minister "considers that there is no justification for further delay in the conversion by the South West Metropolitan Regional Hospital Board of the Kingston Victoria Hosiptal to meet gynæcological needs Since the debate in the House of Commons on Jan 30 (see *Lancet* Feb 10, 1951, p 343) detailed discussions have taken place between the Minister and representatives of the hospital and of the regional board as well as direct between the board and the hospital All the alternative proposals put forward have, however, on examination proved to be unworkable The Minister has, therefore informed the board that they may now proceed to the conversion of the Kingston Victoria Hospital and to the opening of the Claremont Hospital which has been specially adapted for the use of general practitioners"

West London Medico-Chirurgical Society

On Monday, May 21, at 8 30 P.M, the Bishop of Birmingham, the Rt Rev E W Barnes, SC D, F.R.S, will deliver the Cavendish lecture to this society at 1, Wimpole Street, London, W 1 He is to speak on Overpopulation.

Harveian Society of London

The annual Buckston Browne dinner of this society will be held at the Hyde Park Hotel, Knightsbridge, London, S W 1, on Thursday, May 10, at 7 30 P M The principal guest will be Mr L S Amery, C H Further information may be had from the hon secretaries, 11, Chandos Street, London, W 1

Institute of Hospital Administrators

The annual conference of the institute is to be held at Eastbourne on May 17, 18, and 19 when papers will be read on Central Administration and Finance, on Regional and Local Hospital Administration, and on Administrative Problems within the Hospital Sir Wilson Jameson, F.R.C.P, will also open a discussion on the Needs of the Hospital Service Further particulars may be had from the secretary of the institute, 75, Portland Place, London, W 1

Scottish South-Eastern Regional Hospital Board

Owing to ill health Dr J R C Greenlees, D S O, has resigned from the chairmanship of the South Eastern Regional Hospital Board Sir Humphrey Broun Lindsay, D S O, D.L, J P, has agreed to accept appointment as chairman for the time being

THE PSYCHOSOMATIC APPROACH TO PULMONARY TUBERCULOSIS*

GEORGE DAY
M.A., M.D Camb
RESIDENT PHYSICIAN, MUNDESLEY SANATORIUM, NORFOLK

THE psychosomatic approach to pulmonary tuberculosis is beset with difficulties.

First, in order to contract the disease it is necessary to be infected by the tubercle bacillus, and this bacillus is not quite so ubiquitous as it used to be. Secondly, the result of the infection depends largely on inherent somatic resistance. Thus the infected guineapig always dies of generalised tuberculosis, whereas the elephant inoculated with the human type of bacillus does not become diseased, and this has nothing to do with their respective psyches. Thirdly, the human being who hails from a virgin uncivilised island has no racial immunity and will suffer the guineapig's fate if infected, for hereditary resistance to the disease takes generations to develop. Fourthly, resistance to tuberculosis varies not only from race to race but even from family to family. An identical twin shares his fellow twin's morbidity chances, his rate of progress in either direction, and his prognosis. Even when twins have lived separate lives in entirely different circumstances, there seems to be a very high correlation between their behaviours towards tuberculous infection. This correlation is said to be only a sixteenth as high when the twins are fraternal and not identical—which suggests that horoscopes should be cast at the hour of conception and not at the hour of birth.

All the foregoing statements are observable facts, sanctified by statistics, which must not be overlooked when we talk about psychosomatic factors in the *onset* of tuberculosis. We must not forget the guineapig, the elephant, the negro, and the twin.

INFECTION

Let us now consider what happens when the body is invaded for the first time by the tubercle bacillus, and thence what on a purely physical or animal plane determines the course of events.

Some tubercle bacilli enter the fastness of the body. It is no new experience for them: it is how they make their living. It is not an entirely new experience for the body, which has already some degree of inherited resistance, or, to put it another way, some racial memory of how to cope with the situation. What ensues, in brief, is a constitutional upset of short duration—rather like a mild attack of influenza—with tubercle formation at the focus of infection and inflamed and swollen lymph glands in the neighbourhood. Generally this all settles down within six weeks or so, and the body resumes its normal health, which usually persists—so far as the absence of active tuberculosis goes—for the rest of its life. Most of our bodies experience this primary infection before we reach the age of 21. In urban communities 60%, 70%—perhaps 80%—of the adults have been through this little illness, and only a small proportion of them seize the opportunity to develop wider spread disease or to die like guineapigs.

Normal health, I have said, is regained, but thereafter there are three differences.

1. The tubercle bacilli of the invading force are not exterminated but are, we believe, imprisoned in a fortress of living cells where they remain viable for many years.

2. The chemistry of the body is changed. It has become sensitised to tubercle bacilli and their toxins, and responds quite differently towards them the next time they drop in—or break out. This biochemical change has taken place in every cell in the body, and from now onwards even the cells in the skin will react when tuberculin is instilled, thus giving us the positive Mantoux or Pirquet reaction. Whereas at its primary infection the body took the bacilli in its stride in a comparatively methodical and sensible manner, its reaction now to any vagrant bacillus is capricious and unpredictable: sometimes it is indolent, but sometimes it is violent and aggressive even to the extent of self-destroying all contaminated living tissue. Whereas the primary infection was self-limiting, to a matter of six weeks or so, the secondary disease-process is inconclusive—for more like six years.

3. The body has developed some degree of immunity against reinfection with fresh bacilli.

DEVELOPMENT OF TUBERCULOSIS

How then does ordinary adult type phthisis develop? There are two schools of thought. One maintains that *generally*—owing to "lowered resistance" (that convenient legal fiction)—there is leakage of endogenous bacilli from the primary focus to other tissues (via blood stream, bronchial tree, or lymphatic channels). The other school says that *generally* it is due to a superinfection by a massive dose of fresh bacilli from outside, perhaps again helped by temporarily lowered resistance. Such evidence as we have is sufficiently labile to support both schools. I think we are agreed that both mechanisms operate, but we cannot agree which is the more usual.

And it is a matter of some importance to the psychosomatic approach. Under one scheme an individual *needing* pulmonary tuberculosis can develop it merely by lowering his resistance and allowing his primary lesions to leak, whereas under the other scheme he must, in addition, go out and find some more bacilli.

What I want to emphasise is that tuberculosis differs from the ordinary run of so called psychosomatic diseases. It is not so simply acquired as peptic ulcer, hyperpiesis, a gloomy facial expression, and other such occupational diseases, where presumably an emotional habit causes symbolic functional changes, which in turn, if persisted in, cause organic changes in the organ concerned. Not everybody can develop tuberculosis, so to speak, to order. Those members of the community who have never encountered the bacillus, and those with high inherent immunity, will have to content themselves with a substitute—if they really need an illness.

It would therefore be unreasonable to expect to find tuberculosis affecting predominantly any particular personality type. And we do not—apart from the compulsive obsessionals who are always asking for trouble in all directions. Tuberculosis, however, is to be found in all grades of intelligence from the genius to the mentally deficient: in which again it differs from some of the more generally accepted psychosomatic afflictions, such as migraine and asthma, to qualify for which it is almost essential to be up to School Certificate standards.

LOWERING OF RESISTANCE

Let me recapitulate. To develop chronic active pulmonary tuberculosis a person needs some bacilli, some moderately inflammable lungs (not celluloid like the guineapig's nor asbestos like the elephant's), and some internal or external factor which *lowers the resistance to the disease*.

We have now reached the weak link in the chain and must face it and expose our ignorance about it. Certain external environmental factors, such as captivity, starvation, lack of fresh air and sunlight, and overfatigue, we know predispose towards breakdown, and we therefore say they lower the resistance. Again, certain internal factors, such as diabetes, measles, and whooping-cough, similarly lower the resistance. But there always are and always have been healthy bodied people living in comfortable material circumstances who break down with tuberculosis What on earth caused their breakdown, we ask And we have to find out Our job is only half done if we patch them up under sanatorium conditions and then send them back to exactly the same circumstances (whatever they may have been) as brought about their breakdown It would be like resuscitating a near drowned child on the bank and then chucking him back into the deep end without making sure that he could swim

---

* Read before the quarterly meeting of the Royal Medico Psychological Association at Shrewsbury on May 18 1949.

PSYCHOLOGICAL FACTORS

Now if in such cases we take a careful history we find in a great number that they have suffered some major psychological trauma or have experienced some increasing difficulty in adjustment during the previous 18–24 months And, of course, the cold voice of criticism says "But who hasn't? Especially in war time, when major psychological traumata and increasing difficulties in adjustment were ten a penny Where are your controls?" It is really most unsatisfactory We have no quantitative test of a person's resistance to tuberculosis, and no Admiral Beaufort's scale of his psychological maladjustment So there can be no really scientific correlation between the two

One has to admit the weakness of this concept that psychological factors can cause lowered physical resistance, and one has—like the clergyman dealing with an insuperable obstacle—to "face it fearlessly and march boldly on" All the same there is one argument in its favour Psychological factors can very often be observed working during the long months of treatment, influencing both the immediate course of the tuberculosis and the ultimate prognosis, and if they work during the flowering of the disease, surely we may reasonably infer that they were working at its germination? That psychological factors can and do influence the course of tuberculosis, once it is established, can be witnessed by anyone who has the opportunity of watching a patient's progress over a reasonably long period

ILLUSTRATIVE CASES

By way of illustration I will give a couple of thumb nail sketches of patients who have been under my observation during the last two years

Case 1—Ursula, aged 25, was admitted with bilateral tuberculosis, sarcoma of the upper jaw, and diabetes She had had a hard time keeping down a secretarial job, running the flat, and looking after her mother, who was getting more and more peculiar and was a great worry Her mother was the worst case of senile dementia I have ever seen out of hospital, and it was a great relief to the girl to sink back into a bed far from home

Her diabetes was got under control, her maxillary sarcoma (of which two maternal aunts had died before the age of 30) was radically excised and shows no signs (now after 2 years) of any recurrence But her tuberculosis hung fire, and after as much operative interference as we dared make at the time she stabilised at a very low level out of bed only from 2 0 to 4 30 P M, with tea downstairs and a minimal walk in the grounds And there she stuck—for months and months Whenever we tried to extend her hours or her walking exercise she had a slight setback her temperature and her erythrocyte sedimentation rate (E S R) climbed up, and she lost weight, and back to bed she would have to go It was like snakes and ladders without any ladders

All this time she was a good coöperative patient doing her utmost to get well But she knew that on her discharge she would be faced with the dire alternative of either returning to her mother and all the worries that "*brought about her breakdown*" (her own words) or cutting free from her mother—and suffering thereafter the reproaches of her own conscience and her relations' tongues What could one do? One could only wait patiently and hopefully for one of Time's miracles

It was a deadlock that went on for more than a year Then her mother became hallucinated, was certified, and entered a mental hospital, where she is perfectly happy an whence she will never emerge Ursula wept bitterly at th news, which was not entirely unexpected, but since th day she has got on, has trebled her exertions with impunit and will, I am now hopeful, make a useful recovery An amazingly enough, her 18 month old half crown cavity her right lung has healed almost completely during the la 3 months Tomograms taken 4 days ago show in its plac a small area of fine honeycombing She will probably kee her diabetes as a memento

Postscript May, 1951—She has now been at home main taining perfectly good health for nearly two years She sti has her diabetes

Case 2—Jennifer, aged 16, developed tuberculosis in bot lungs, and was treated at home for 2 years without muc progress in either direction Her tuberculous father wa already under treatment at home, having been discharged from a sanatorium as incurable Hers was an *extremely* indolent form of early tuberculosis Then she coughed up some blood and was sent in panic haste to the sanatorium, where she made practically no progress for the first 6 months in spite of streptomycin She, too, stabilised at a low level and any attempt at pushing her on was rewarded with ris of temperature and E S R—and back to bed again

This went on for 9 months Then her tuberculous manic depressive father, who for the past 10 years had cast a hecti gloom over the home, died At once the girl began to improve and in course of time was fit enough to go home on 10 days leave She returned in a state of hysteria and tears He mother, deprived of her invalid husband, focused all he anxious solicitude on her daughter "She worries and fusse over me and everything I do the whole time I've lost ever bit of the self confidence I had been gaining this past year" The girl was not so well and threatened to stagnate again at a low stability

What could one do? Again hope for one of Time's miracles. It came Her mother became so depressed—so obviously depressed—that her doctor referred her to a psychiatrist who gave a course of electric convulsion therapy with dramatic effect She became hypomanic, jolly, and carefree The daughter rapidly completed her convalescence and went home I have since learnt that she is well and happy and is attending an art school—an ambition which her mother had vetoed before her electrocutions

I could go on almost indefinitely giving this sort of testimony about the conscious state of mind and the *course* of the disease

Personally—and in spite of the guineapig, the elephant, the negro, and the twin, and all the other reasonable arguments put forward by the sceptics—I am convinced that in some cases disturbance of the psyche can and does *precipitate* the active disease process But that conviction does not make life any easier My next difficulty is to decide on what level the disturbance is operating and on what level it should be tackled I can make this clearer by examples Take the compulsive obsessional type His behaviour pattern can most easily be accepted as tending directly on a somatic or near somatic level to lower his resistance to the disease In pure culture he slave drives himself at his work, undertaking other people's work as well as his own, neglects both bed and board, enjoys no relaxations, and refuses to give in to feelings of fatigue He builds his own Railway of Death On a purely physical plane he is lowering his resistance to the disease by flirting with the classical quartet—captivity, starvation, lack of fresh air and sunlight, and over fatigue But on another level I wonder whether his guilt feelings, which allow him no peace, welcome tuberculosis as yet another cross for him to bear, yet another form of self punishment? There is undoubtedly a higher percentage of these obsessionals among the tuberculous than in the population at large (This may, of course, be equally true of other diseases, I do not know) They do not make good patients and they do not do very well on the milder forms of therapy They mostly come sooner or later to thoracoplasty Is it too fanciful to wonder whether the pain and mutilation and the sacrifice of a few ribs have a deeper significance to the patient—an expiation of his guilt feelings similar to that brought about (it is my contention) by electric convulsion therapy on the guiltily depressed ?

Incidentally, among sanatorium patients there is a curious hierarchy There are the Oldest Inhabitants, of course, they are the Prefects or Wise Men whose views carry much weight Those who have successfully undergone major surgical operations are held in as much esteem as if they had gained their school colours They are the Bloods And so on down the scale The patient whose treatment has been purely conservative—rest in bed followed by graduated exercise, without even a phrenic crush or a course of streptomycin—is very small beer indeed It strikes me very forcibly that at some primitive level of the group unconscious the ordeal of suffering at the hands of the surgeon must be regarded as a ritual of initiation or perhaps of purification

Another cause for breakdown on the near somatic level is unhappiness I might call it Unhappiness in Captivity, where the fetters are an uncongenial job, a deadening family life such as obtained in the two cases I have described, or an unhappy marriage—something inescapable or with apparently only a fire awaiting him who might leap out of the frying pan This sort of situation, taking as it does all zest out of life, all taste out of food, all repose out of sleep, must inevitably starve the body of some of its needs, alter its metabolism, and lower its resistance to disease Can it be that on a deeper level the pent up and frustrated aggression is turned in on itself and sets about destroying the organism with whatever weapons are at hand—in this case the tubercle bacilli ? Can it be that the patient is sick of his life, and the Death Wish replaces the helmsman ?

This sort of case is easy to spot—where the conflict is on a conscious level I doubt whether there is a sanatorium superintendent in the world who has not on some occasion exclaimed "If only someone would shoot this patient's mother (wife, husband, or father, as the case may be)" Moreover, this is the sort of case in which one can often do something to help, even though it only amounts to waiting patiently for Time to bring about its healing A full frank discussion of the patient's whole life situation—not once but repeated at intervals, for repetition is just as important here as in any other form of remedial exercises—can help the patient to find a way of altering his emotional attitude towards it Very often all he needs is time, a renewal of courage, and the feeling that he has a friend behind him in his new venture

But it is not always as easy as that The presence of a conscious conflict, or a rationalised anxiety, can be very misleading It may be merely the visible expression of some deeper maladjustment which is ready to provide other conscious conflicts to replace the one we may successfully resolve I remembered how annoyed I felt once when in Army psychiatry I successfully dispelled a tuberculophobia on a purely rational level, and after a few days' peace and gratitude the patient became convinced that he had cancer of the stomach. Thus I learned the truth of the platitude "fear is hydra headed"

Then there are those cases in which no psychological disturbance whatever can be found on a conscious level and yet there must be something amiss deeper down which is in some way connected with their tuberculosis The obsessional type comes to mind at once in this connection But there are others

One patient, while enjoying normal physical health, began having a recurrent dream that he was being driven through lovely countryside on a late summer afternoon enjoying the beauties of cloud field, and foliage as never before—very poignantly—because his destination was a prison from which he would never emerge again Eventually, $3^{1}/_{2}$ years later the dream came true in every detail

Another patient, a woman, developed a rather more subtle prescient dream which recurred several times during the months before she fell ill She dreamed that she was on a railway station about to make a journey she knew not where While looking for a seat she put down her suitcase, which contained all that she possessed, and when she looked round for it it had disappeared

Then there are those quiet spoken, gentle, cheerful little patients, whose lives and circumstances seem the quintessence of normality but whose Rorschach reactions are terrifyingly full of high explosive stuff—battle, murder, sudden death, anxieties, destructive aggressive impulses, pain, and cruelty I have learnt to make mental reservations when giving a prognosis in such cases, even though clinically and radiologically their disease appears to be of slight extent They may get well enough to return home and to their work, but they are apt to break down again I have also learnt to be far happier about them if their crust gives way and reveals an apparent deterioration of their personality in the matter of a depression or chronic anxiety But I rather draw the line at frank psychotic episodes

Sometimes I wonder if we are not barking up the wrong tree, and whether tuberculosis, cancer, and such destructive diseases should not sometimes be regarded as psychotic conversions It is notorious that, if one succeeds in depriving an asthmatic of his asthma, there is a chance of his becoming schizophrenic I have known depressed tuberculous patients who, when discharged, improved, and, improving, have gone home and committed suicide The near suicide of a patient I had under my care jerked him out of his depression and set him up for five years before he tried again, next time successfully

It is not a very attractive hypothesis, because it makes one feel more helpless than ever

So far I have been talking as if the road from psyche to soma were a one way street It is not Neither is psyche always the horse and soma the cart They are much more like horses in double harness, inasmuch as if one falls lame the other suffers and has to adjust to the situation And this adds yet another difficulty to the study of sick patients Their bodily illness affects their psyche—their whole personality—dynamically They will not stand still but are undergoing change the whole time

RECOVERY AND THE DOCTOR

The patient who falls sick with tuberculosis is quite often pretty anxious at first—even panicky Emotionally he regresses and wants Daddy to Make Him Well Again While he is lying in bed for several months with all his little wants attended to by Mother Figure nurses and God the Father doctors he is apt to regress further—if not quite to the womb, at least to cradlehood This regression seems to be as necessary a phase in therapy as the transference situation (with which it is surely linked ?) is in analysis The Kingdom of Heaven, we are told, is open only to those who are born again

In course of time he is born again, by the time he becomes ambulant he has become a member of the family and identifies himself with the group This phase of group identification, too, I regard as highly desirable, if not absolutely essential, for psychological reorientation It is a phase comparable to puberty or adolescence The group, untutored and leaderless, is a much more powerful psychotherapeutic instrument than any half baked psychiatric doctor like myself It is the patients who heal each other

Does the doctor play no part whatsoever ? Well, by joining with the group in its creative activities he can do a little to preserve harmony drawing out some inhibited member, damping down the persistent struggle for group domination, and encouraging each individual to realise that the group cannot be quite the same if he does not participate—much as a play producer strives to achieve balance and integrity among his players

But I must confess, we cannot do much I learned at Northfield during the war that the hospital itself was the real therapeutic agent, and that patients in a ward with a good morale did better than others in a disgruntled bear garden Quite late I discovered, too, to my humiliation, that going swimming or playing basket ball with my patients brought about more therapy than if I had spent treble the hours in psychiatric interviews I did not tell the Commanding Officer this He might have commented drily, and with some justification, that it evidently suited *my* complaint Instead I wrote a little hymn, for use in Army psychiatric messes, which I still occasionally hum to myself The refrain goes

Grant us, Lord, a proper sense
Of therapeutic impotence
Keep us humble, Lord
AMEN

My ideas, and the patterns into which they fall, owe much to Dr S H Foulkes, Dr James L Halliday, and Dr Eric Wittkower To their writings, and to the lively discussions I have enjoyed with them, I make my grateful acknowledgments

PARALYSES FOLLOWING IMMUNISING INJECTIONS

MEASURES CALCULATED TO DIMINISH THE RISK

GUY BOUSFIELD
M.D , Lond
DIRECTOR, CAMBERWELL LABORATORIES

THE investigations described below were, in part, instigated by a remark made to me by Sir Allen Daley, who observed that paralytic poliomyelitis following injections of diphtheria prophylactic or combined diphtheria toxoid and pertussis vaccine seemed to occur less often in infants under 1 year of age than in older children

Although many infants are immunised between the ages of 8 and 12 months, relatively few are injected earlier If the incidence of post injection paralysis rises notably over the age of 1 year, it might diminish in an equally striking manner if the injections were given in the first month or two of life

Sir Allen's observation immediately suggested to me that small infants might have some form of immunity to poliomyelitis like the passive immunity to diphtheria possessed by many babies during the early months of life Despite the fact that there does not seem to be much serological evidence of antibodies in adults to show that there is any widespread immunity to poliomyelitis, it is just possible that some such immunity does exist, and that it is due to some at present undetermined factor The defence of the infant might well be impermeability of the mucosæ

In any attempt to estimate the risk of poliomyelitis in the earlier period of life, the first step seemed to be to study the incidence of the disease in children under 1 year of age, dividing the cases into three month groups, but before proceeding to this analysis it will be instructive to study the age incidence of notified cases compiled from the Registrar General's returns for 1946–49 (fig 1) It will be noticed that the morbidity is far less in children aged less than 1 year than in the older children, the period of greatest risk apparently falling between the 2nd and 5th years

These findings tend to fit in rather well with Sir Allen Daley's observation Unfortunately, official records of notifications do not break down the morbidity in children aged less than 1 year into any shorter periods Thus it became necessary to investigate this aspect Many medical officers of health kindly analysed notifications received by them during the 4 years 1946–49 and furnished this information privately In addition, the General Register Office collected data relating to the first three quarters of 1950 It has thus been possible to construct two separate curves (fig 2) and to plot the mean The figures which it has been possible to obtain are not large, but they are culled from widely distributed areas of these islands, and should be fairly representative. One difficulty in producing larger totals is the relative infrequency of poliomyelitis in small infants In perusing fig 2, to keep this low incidence in mind it is well to refer once more to fig 1, and to recollect that only the children aged less than 1 year are being studied In considering fig 2 certain facts must be borne in mind There may be more frequent errors in the diagnosis of poliomyelitis in infants under 6 months of age, and some cases of poliomyelitis may have been missed or attributed to other conditions Again, there has undoubtedly been unsatisfactory diagnosis and notification of poliomyelitis in the past, which may render statistics somewhat misleading Further, the really small child may not be so often exposed to infection as are older children However, even allowing for these factors, the steady trend of the curve in fig 2 is reminiscent, in reverse, of the natural immunity curve found in the case of diphtheria (fig 3)

Whether or not the curve in fig 2 is attributable to passive immunity to poliomyelitis seems to be immaterial The fact remains that the disease, in recognisable form, is relatively infrequent under the age of 6 months, and we ought to be able to take advantage of this fact in any attempt to avoid paralytic sequelæ to injections of diphtheria, and possibly other, prophylactics If such treatment can be shown to be both effective and durable, it seems that inoculation against diphtheria should be undertaken as early as possible in life

PRODUCTION OF IMMUNITY IN INFANTS

There is already considerable evidence that it is feasible to immunise infants against diphtheria during

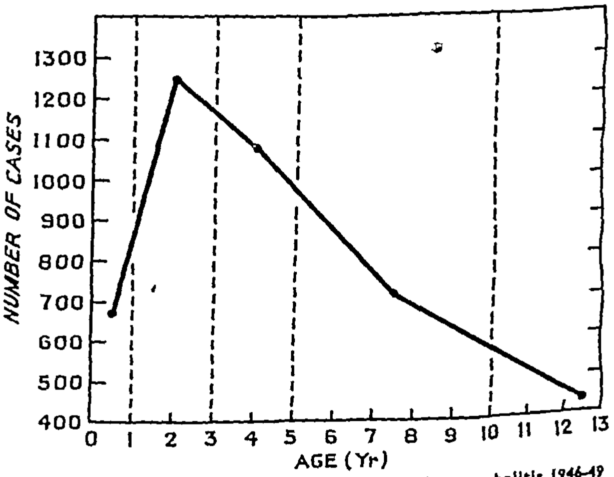

Fig 1—Age-distribution of poliomyelitis and polio-encephalitis 1946-49 The curve is constructed from the Registrar General's tables for infantile paralysis and polio-encephalitis in the civilian population for 1946-49 The interrupted vertical lines show the limits of the age-periods adopted in those tables To obtain a rough approximation of the trend of the curve of age-incidence the number of cases in each group has been divided by the number of years included in the group and the resulting figure has been plotted at the middle point in the age-group For example, there were 670 cases below the age of 1 year; and from the beginning of the 1st year to the end of the 2nd there were 2501 cases which figure divided by two gives 1250·5 This has been plotted on the line of the second year It is assumed that the numbers of children exposed to risk at each year of age within the grouped age-periods plotted, is about the same.

the first few months of life (Vahlquist 1949, Bousfield 1949, Barr et al. 1950, di Sant'Agnese 1950, Sauer and Tucker 1950)

It will be of interest to cite some figures published previously (Bousfield 1949), because it has now been possible to study these cases at relatively long range In the original article a description was given of 97 infants, of an unknown state of immunity of maternal origin, aged 2-5¹ months, who were treated by two different methods Reference to table I will show that a noteworthy proportion of these children would have been Schick negative at the time of inoculation.

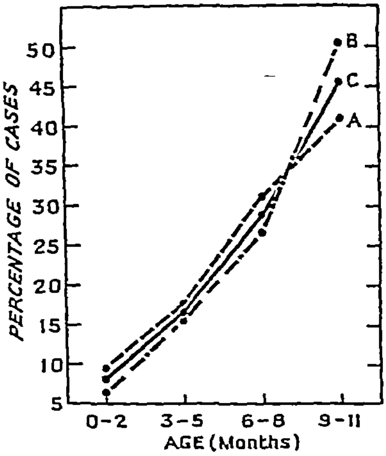

Fig 2—Incidence of poliomyelitis in infants aged less than 1 year A analysis of the General Register Office of 192 cases occurring in the first three-quarters of 1950 B information obtained by the author relating to 183 cases occurring between 1946 and the end of 1949 This information was supplied privately by medical officers of health, C average results obtained from the 375 cases contained in the two series.

Group A, comprising 46 children (aged 3–5 months) were given a single intramuscular injection of 1 0 ml of combined diphtheria toxoid and pertussis vaccine (P.D & Co) This contained 25 Lf units of diphtheria toxoid in the form of P.T.A.P The children received post-Schick tests when they reached the age of 1 year The results were

Post Schick positive 3 negative 43 (post-Schick negative rate 93 5 %)

Group B, containing 51 children (aged 2–5 months) received two intramuscular injections of 0 5 ml of the same combined prophylactic at an interval of a month The diphtheria toxoid dosage was thus 12 5 Lf units on each occasion. These children were post-Schick tested at the age of 1 year The results were

Post Schick positive 0 negative 51 (post-Schick negative rate 100 %)

To understand the significance of these figures, reference should be made to table I This gives the result of an investigation, in and around London, of the Schick-negative rate in untreated children aged 2–12 months It should here be mentioned that all Schick tests recorded here were done with Wellcome toxin and control The use of control is absolutely essential in post Schick testing, otherwise there will be erroneous positive readings

The data in table I have been set out in fig 3, and from this it will be noted that, at the age of 12 months, the age at which groups A and B were post Schick tested, practically every child would normally have lost any maternally bestowed immunity and become Schick positive, were it not for the inoculations carried out in the early months of life

The results of retesting groups A and B, when compared with the expectation in untreated children, show just how efficacious the immunisation was, especially in group B

DURATION OF IMMUNITY IN INFANTS

The question will be raised as to how long an immunity will last when infants are inoculated at a tender age It is now possible to provide some evidence on this point

Of the 97 children treated as described above it has now been possible to retest 52, some 2 years or slightly more after the original inoculation Group A (single injection only) provided 31 children for long range test, and group B produced 21 cases The results appear in table II

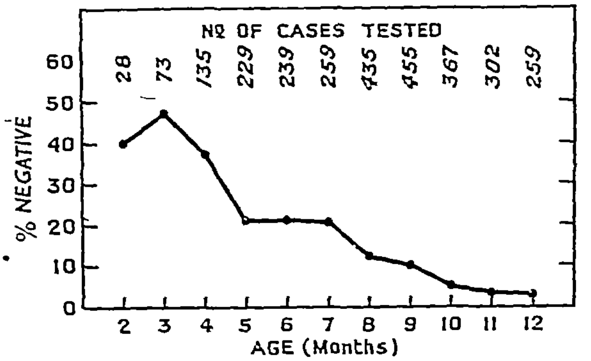

Fig 3—Primary Schick tests in 2781 infants Results related to age

These are the bare facts Their precise significance must now be considered During the 18 months or so which elapsed between the original post Schick tests and the long range tests there had been little, if any, diphtheria infection in the locality to boost the immunity of the infants Permanence of the Schick-negative state due to this cause can be discounted On the other hand, a Schick test is known to exercise a noteworthy boosting effect in persons who have previously been immunised or who have a basal immunity

Group A had one powerful primary stimulus, followed by the minute additional stimulus of the Schick test some 5–8 months later Thus accurate definition demands that these infants should be regarded as having been treated by a two injection procedure Had the Schick test, done at the age of 1 year, been replaced by a normal second dose of prophylactic the results of the long range test might have been better

By the same standard, group B must be considered to have received three injections two of P.T.A.P and a Schick stimulus several months later The point at issue, however, is not how many injections have to be given to procure a lasting immunity in infants, but rather can it be done at all? It is submitted that table II provides an affirmative answer over a reasonable period of time Judging from past experience, what lasts for such a time may well endure much longer It will be necessary to observe infants at longer range to prove this beyond all doubt Measures for immunising small infants are given below

TABLE I—PRIMARY SCHICK TESTS ON INFANTS

Age (mos)	No of cases	Positive	Negative	% Schick negative
2	28	17	11	39 3
3	73	39	34	46 6
4	135	85	50	37 0
5	229	180	49	21 4
6	239	187	52	21 8
7	259	206	53	20 5
8	435	385	50	11 5
9	455	409	46	10 1
10	367	350	17	4 6
11	302	291	11	3 6
12	259	252	7	2 7

Infant Immunity Curve—The form of curve in fig 3 is of some interest because it is based on 2781 primary tests and should therefore be fairly comprehensive Apart from the 2 month age group, which comprised only 28 infants, the decline in immunity is as would be expected, except for the abrupt fall to the 5th month, and the definite flattening of the curve covering the 6th and 7th months Weaning might have something to do with this, but it is difficult to see what mechanism could produce this effect It is, however, clear that, at does not participate—much as a play producer strives to achieve balance and integrity among his players.

But I must confess, we cannot do much. I learned at Northfield during the war that the hospital itself was the real therapeutic agent, and that patients in a ward with a good morale did better than others in a disgruntled bear garden. Quite late I discovered, too, to my humiliation, that going swimming or playing basket ball with my patients brought about more therapy than if I had spent treble the hours in psychiatric interviews. I did not tell the Commanding Officer this. He might have commented drily, and with some justification, that it evidently suited *my* complaint. Instead I wrote a little hymn, for use in Army psychiatric messes, which I still occasionally hum to myself. The refrain goes

Grant us, Lord, a proper sense
Of therapeutic impotence
Keep us humble, Lord
AMEN

My ideas, and the patterns into which they fall, owe much to Dr S. H. Foulkes, Dr James L. Halliday, and Dr Eric Wittkower. To their writings, and to the lively discussions I have enjoyed with them, I make my grateful acknowledgments.

PARALYSES FOLLOWING IMMUNISING INJECTIONS

MEASURES CALCULATED TO DIMINISH THE RISK

GUY BOUSFIELD
M.D., Lond
DIRECTOR, CAMBERWELL LABORATORIES

THE investigations described below were, in part, instigated by a remark made to me by Sir Allen Daley, who observed that paralytic poliomyelitis following injections of diphtheria prophylactic or combined diphtheria toxoid and pertussis vaccine seemed to occur less often in infants under 1 year of age than in older children.

Although many infants are immunised between the ages of 8 and 12 months, relatively few are injected earlier. If the incidence of post-injection paralysis rises notably over the age of 1 year, it might diminish in an equally striking manner if the injections were given in the first month or two of life.

Sir Allen's observation immediately suggested to me that small infants might have some form of immunity to poliomyelitis like the passive immunity to diphtheria possessed by many babies during the early months of life. Despite the fact that there does not seem to be much serological evidence of antibodies in adults to show that there is any widespread immunity to poliomyelitis, it is just possible that some such immunity does exist, and that it is due to some at present undetermined factor. The defence of the infant might well be impermeability of the mucosæ.

In any attempt to estimate the risk of poliomyelitis in the earlier period of life, the first step seemed to be to study the incidence of the disease in children under 1 year of age, dividing the cases into three-month groups; but before proceeding to this analysis it will be instructive to study the age-incidence of notified cases compiled from the Registrar General's returns for 1946–49 (fig. 1). It will be noticed that the morbidity is far less in children aged less than 1 year than in the older children, the period of greatest risk apparently falling between the 2nd and 5th years.

These findings tend to fit in rather well with Sir Allen Daley's observation. Unfortunately, official records of notifications do not break down the morbidity in children aged less than 1 year into any shorter periods. Thus it became necessary to investigate this aspect. Many medical officers of health kindly analysed noti-fications received by them during the 4 years 194 and furnished this information privately. In addition the General Register Office collected data relating to t first three quarters of 1950. It has thus been possible t construct two separate curves (fig. 2) and to plot t mean. The figures which it has been possible to obta are not large, but they are culled from widely distribute areas of these islands, and should be fairly representative. One difficulty in producing larger totals is the relativ infrequency of poliomyelitis in small infants. I perusing fig. 2, to keep this low incidence in mind it is well to refer once more to fig. 1, and to recollect that only the children aged less than 1 year are being studied. In considering fig. 2 certain facts must be borne in mind. There may be more frequent errors in the diagnos of poliomyelitis in infants under 6 months of age, and some cases of poliomyelitis may have been missed or attributed to other conditions. Again, there has un-doubtedly been unsatisfactory diagnosis and notification of poliomyelitis in the past, which may render statistics somewhat misleading. Further, the really small child may not be so often exposed to infection as are older children. However, even allowing for these factors, the steady trend of the curve in fig. 2 is reminiscent, in reverse, of the natural immunity curve found in the case of diphtheria (fig. 3).

Whether or not the curve in fig. 2 is attributable to passive immunity to poliomyelitis seems to be immaterial. The fact remains that the disease, in recognisable form, is relatively infrequent under the age of 6 months, and we ought to be able to take advantage of this fact in any attempt to avoid paralytic sequelæ to injections of diphtheria, and possibly other, prophylactics. If such treatment can be shown to be both effective and durable, it seems that inoculation against diphtheria should be undertaken as early as possible in life.

PRODUCTION OF IMMUNITY IN INFANTS

There is already considerable evidence that it is feasible to immunise infants against diphtheria during

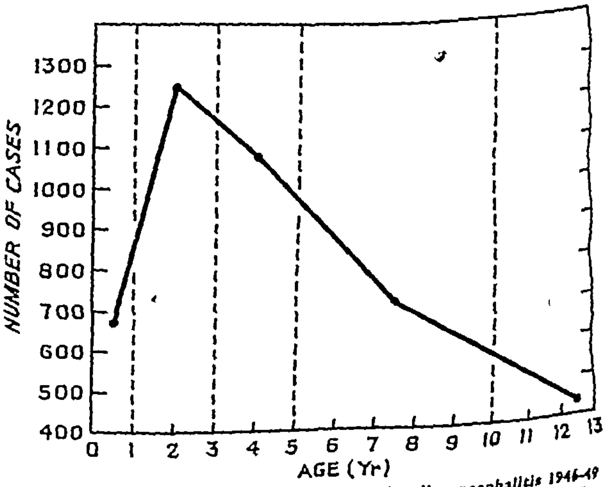

Fig. 1—Age-distribution of poliomyelitis and polio-encephalitis 1946–49. The curve is constructed from the Registrar-General's tables for infantile paralysis and polio-encephalitis in the civilian population for 1946–49. The interrupted vertical lines show the limits of the age-periods adopted in those tables. To obtain a rough approximation of the trend of the curve of age-incidence the number of cases in each group has been divided by the number of years included in the group, and the resulting figure has been plotted at the middle point in the age-group. For example there were 670 cases below the age of 1 year; and from the beginning of the 1st year to the end of the 2nd there were 2501 cases, which figure, divided by two gives 1250.5. This has been plotted on the line of the second year. It is assumed that the numbers of children exposed to risk at each year of age, within the grouped age-periods plotted, is about the same.

the first few months of life (Vahlquist 1949, Bousfield 1949, Barr et al 1950, di Sant'Agnese 1950, Sauer and Tucker 1950)

It will be of interest to cite some figures published previously (Bousfield 1949), because it has now been possible to study these cases at relatively long range In the original article a description was given of 97 infants, of an unknown state of immunity of maternal origin, aged 2–5 months, who were treated by two different methods Reference to table I will show that a noteworthy proportion of these children would have been Schick negative at the time of inoculation.

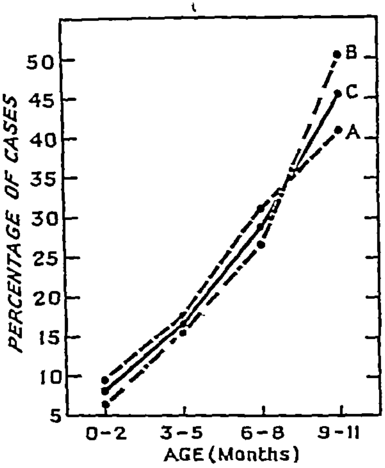

Fig 2—Incidence of poliomyelitis in infants aged less than 1 year A analysis of the General Register Office of 192 cases occurring in the first three-quarters of 1950 B, information obtained by the author relating to 183 cases occurring between 1946 and the end of 1949 This information was supplied privately by medical officers of health C average results obtained from the 375 cases contained in the two series.

Group A, comprising 46 children (aged 3–5 months) were given a single intramuscular injection of 1 0 ml. of combined diphtheria toxoid and pertussis vaccine (P.D & Co) This contained 25 Lf units of diphtheria toxoid in the form of P T.A.P The children received post-Schick tests when they reached the age of 1 year The results were

Post Schick positive 3 negative 43 (post Schick negative rate 93 5 %)

Group B, containing 51 children (aged 2–5 months) received two intramuscular injections of 0 5 ml of the same combined prophylactic at an interval of a month. The diphtheria toxoid dosage was thus 12 5 Lf units on each occasion These children were post Schick tested at the age of 1 year The results were

Post Schick positive 0 negative 51 (post-Schick negative rate 100 %)

To understand the significance of these figures, reference should be made to table I This gives the result of an investigation, in and around London, of the Schick negative rate in untreated children aged 2–12 months It should here be mentioned that all Schick tests recorded here were done with Wellcome toxin and control The use of control is absolutely essential in post Schick testing, otherwise there will be erroneous positive readings

The data in table I have been set out in fig 3, and from this it will be noted that, at the age of 12 months, the age at which groups A and B were post Schick tested, practically every child would normally have lost any maternally bestowed immunity and become Schick-positive, were it not for the inoculations carried out in the early months of life

The results of retesting groups A and B, when compared with the expectation in untreated children, show just how efficacious the immunisation was, especially in group B

DURATION OF IMMUNITY IN INFANTS

The question will be raised as to how long an immunity will last when infants are inoculated at a tender age It is now possible to provide some evidence on this point

Of the 97 children treated as described above it has now been possible to retest 52, some 2 years or slightly more after the original inoculation Group A (single injection only) provided 31 children for long range test, and group B produced 21 cases The results appear in table II

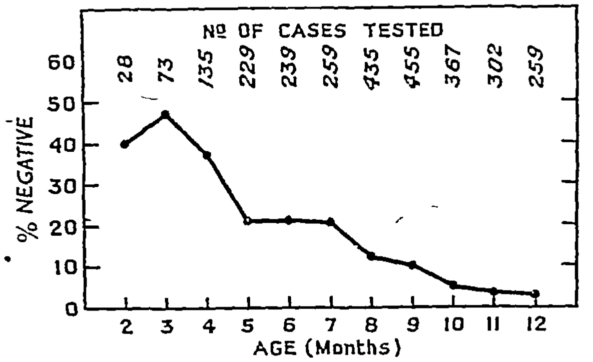

Fig 3—Primary Schick tests in 2781 infants Results related to age

These are the bare facts Their precise significance must now be considered During the 18 months or so which elapsed between the original post Schick tests and the long range tests there had been little, if any, diphtheria infection in the locality to boost the immunity of the infants Permanence of the Schick negative state due to this cause can be discounted On the other hand, a Schick test is known to exercise a noteworthy boosting effect in persons who have previously been immunised or who have a basal immunity

Group A had one powerful primary stimulus, followed by the minute additional stimulus of the Schick test some 5–8 months later Thus accurate definition demands that these infants should be regarded as having been treated by a two injection procedure Had the Schick test, done at the age of 1 year, been replaced by a normal second dose of prophylactic the results of the long range test might have been better

By the same standard, group B must be considered to have received three injections two of P T A.P and a Schick stimulus several months later The point at issue, however, is not how many injections have to be given to procure a lasting immunity in infants, but rather can it be done at all? It is submitted that table II provides an affirmative answer over a reasonable period of time Judging from past experience, what lasts for such a time may well endure much longer It will be necessary to observe infants at longer range to prove this beyond all doubt Measures for immunising small infants are given below

TABLE I—PRIMARY SCHICK TESTS ON INFANTS

Age (mos)	No of cases	Positive	Negative	% Schick-negative
2	28	17	11	39 3
3	73	39	34	46 6
4	135	85	50	37 0
5	229	180	49	21 4
6	239	187	52	21 8
7	259	206	53	20 5
8	435	385	50	11 5
9	455	409	46	10 1
10	367	350	17	4 6
11	302	291	11	3 6
12	259	252	7	2 7

Infant Immunity Curve—The form of curve in fig 3 is of some interest because it is based on 2781 primary tests, and should therefore be fairly comprehensive Apart from the 2 month age group, which comprised only 28 infants, the decline in immunity is as would be expected, except for the abrupt fall to the 5th month, and the definite flattening of the curve covering the 6th and 7th months Weaning might have something to do with this, but it is difficult to see what mechanism could produce this effect It is, however, clear that, at

TABLE II—PERMANENCY OF THE SCHICK NEGATIVE STATE IN INFANTS INOCULATED AT THE AGE OF 2–5 MONTHS RETESTS 2 YEARS AFTER INOCULATION

Group of infants	No. of cases	Post Schick positive	Post Schick negative
Group A	31	2	29
Group B	21	0	21

Permanency of Schick negative state (both methods) 96%

the age of 1 year, all but a few infants have lost their passive immunity.

AGE AT WHICH IMMUNITY CAN BE PROCURED

The feasibility of immunising infants having been demonstrated, the next point which required study was how early in life active immunity could be shown to have been established. For this purpose a further 174 small infants, all previously shown to be Schick positive, were treated by different methods. All were aged 2–5 months at the start of the immunising course, and in each case post Schick tests were made about a month after the last injection. Occasionally the interval was slightly longer.

Group C received two intramuscular injections of 0·5 ml of combined diphtheria and pertussis prophylactic (P.D.) at an interval of 28 days.

Group D received two or three subcutaneous injections of 0·5 ml of fluid toxoid in buffered saline solution at intervals of 14 days, or 14 days and 28 days.

Group E received a single subcutaneous injection of P.T.A.P. mixed with fluid toxoid. This mixture is later referred to as F.P.T.

The results are shown in table III.

It is not suggested that the age of Schick conversion recorded in table III by any means necessarily constitutes the low limit of possibility. The new experimental antigen, F.P.T., has made a good showing (see below). Clearly, if infants could be obtained for treatment at the age of 2 months or less, there is no reason why most of them should not have an effective potential immunity conferred on them, by a single subcutaneous injection of F.P.T., by the time they are 3 months old. A secondary stimulus could be applied later at a convenient time.

Part of the trouble in inquiries such as those embodied here is due to the difficulty in educating parents to bring infants for treatment at a tender age. The idea of having children inoculated at the age of about 9 months has prevailed so long that it is difficult to change it. Fig. 3 shows that the vast majority of infants are brought to clinics at the age of 8–10 months.

TABLE III—AGE AT WHICH IMMUNITY CAN BE SHOWN TO HAVE BEEN ESTABLISHED IN SCHICK POSITIVE INFANTS INOCULATED AT THE AGE OF 2–5 MONTHS

Group	No. of cases	Post Schick positive	Post Schick negative	Average age at inoculation (mos.)	Average age at post Schick test (mos.)
C	112	2	110	4·0	6·3
D	20	0	20	4·5	7·0
E	42	0	42	4·5	5·7

Total cases in all groups 174 Conversion rate 98·9%

Table III thus offers further evidence of the feasibility of immunising the small infant. It also shows that this can be effected at the age of about 6 or 7 months, before the risk of poliomyelitis becomes significant. Finally there is a little evidence that subcutaneous injections of purified toxoid produce a satisfactory response in very young infants, a point which will be found to be of possible significance later.

ROUTE OF INJECTION AND CHOICE OF PROPHYLACTICS

It is now fairly generally accepted that intramuscular injections made when poliomyelitis is prevalent occasionally tend to be followed by paralysis of that muscle or of an associated group. Probably persons so affected already have the virus in their systems, or become infected about the time of injection. Intramuscular injections may possibly convert a non-paralytic type of poliomyelitis into the paralytic form. The diphtheria prophylactics which seem to be chiefly connected with such lesions after intramuscular inoculation are A.P.T. combined with pertussis vaccine and, to a lesser extent, A.P.T. given alone.

A twofold change in procedure seemed to be indicated when these facts became known. The first thing was to abandon intramuscular injection, and to try injecting by the shallow subcutaneous route. The second point was to use a prophylactic which could be injected in such a manner, without the production of excessive local reaction, while at the same time providing an efficient immunity response. These considerations absolutely ruled out combined diphtheria and pertussis prophylactic, and even rendered the injection of A.P.T. rather undesirable.

TABLE IV—EFFECTS OF TWO SUBCUTANEOUS INJECTIONS OF 0·3 ML. OF P.T.A.P., GIVEN AT A MONTHLY INTERVAL, TO SCHICK POSITIVE CHILDREN UNDER THE AGE OF 2 YEARS

No. of cases	Interval between last injection and post-Schick test (mos.)	Post-Schick results		Conversion rate
		Positive	Negative	
62	2	0	62	100%
231	3	1	230	99·6%
293		1	292	99·7%

In the course of considerable research into the optimal aluminium phosphate content of Holt's purified toxoid, aluminium phosphate precipitated (P.T.A.P.), large numbers of subcutaneous injections were given to investigate the relation between the formation of subcutaneous nodules and the antigenic response (Bousfield 1947a).

Parents having been warned not to worry if a small hard lump came up under the skin, practically no complaints of untoward reaction were met with after the injection of small Schick positive children with P.T.A.P. by the subcutaneous route. This preliminary experience paved the way for investigation of the effect of subcutaneous injections of standard P.T.A.P. on a group of 293 children aged less than 2 years. All the infants were initially shown to be Schick positive. They received two injections of P.T.A.P. 0·3 ml. just under the skin, over the deltoid muscle in the arm, the interval between the inoculations being a month. Retests were made at the intervals shown in table IV. It will be agreed that these results are virtually perfect from the immunological aspect.

At this point it may be well to consider how much progress has been made in building up a scheme for safe and efficient inoculation. The age of theoretical least danger from poliomyelitis has been indicated with a degree of probability and the feasibility of inoculating very small infants has been shown, originally by intramuscular injections. The durability of the immunity bestowed by injections given early in life has been shown to be reasonably good, and it has been shown that a very high Schick conversion rate is obtainable with two strictly subcutaneous injections of P.T.A.P. at a monthly interval.

Here a word of warning must be given. The site for a subcutaneous injection must be carefully chosen. The skin over the fleshy part of the deltoid in the arm, well

TABLE V—EFFECTS OF SUBCUTANEOUS INJECTIONS OF FLUID TOXOID (HOLT—BATCH 3540) DOSAGE ON EACH OCCASION 0·5 ML. POST SCHICK TESTS DONE A MONTH AFTER FINAL INJECTION

No of injections	Interval between doses (days)	No of cases	Post Schick		Conversion rate
			Positive	Negative	
3	0–14–28	127	1	126	99 2%
2	0–14	124	9	115	92 7%
1	—	30	14	16	53 3%

clear of the shoulder, is probably as good a site as any Areas in which the musculospiral nerve could be involved must be scrupulously avoided, or wrist drop may supervene Injections over the deltoid have given no trouble whatsoever These injections should be strictly subcutaneous, not shallow intramuscular

This investigation of the use of subcutaneous P T.A P and fluid toxoid was conducted during an epidemic of poliomyelitis, and many thousands of other subcutaneous injections were administered throughout this period, without a suspicion of any paralytic sequelæ Working under similar conditions, but using intramuscular injections, during a previous epidemic of poliomyelitis, I had met with several cases of post-injection paralysis

INVESTIGATION OF PROPERTIES OF AN ANTIGEN WITHOUT MINERAL CARRIER

Because some people feared that it was the aluminium hydroxide in prophylactics such as A.P T which might be the irritant involved in the production of post-injection poliomyelitic paralyses, it was resolved to try to dispense with any aluminium compound The mind went back to those days when one used the old formol toxoid, of which three spaced injections were necessary Excellent antigenic response was obtainable with this prophylactic, but some persons developed severe local reactions after its use This was due largely to various impurities in the material.

Today the position is different, mainly owing to the pioneer work of L B Holt in the production of a diphtheria toxoid of extreme purity, such as is embodied in his P T.A.P (Holt 1947, 1950)

It was resolved to try the effect of injecting this pure toxoid without any mineral carrier, and it was considered that a reasonable toxoid content would be 50 or 60 Lf per ml. Holt kindly prepared a batch of his pure toxoid in buffered saline solution, the strength being 60 Lf per ml. Three groups of Schick positive children aged less than 2 years were treated with this prophylactic subcutaneously This material is henceforth referred to as F T Details of various procedures adopted are given in table V

The single injection series was curtailed, since it was clear that no useful purpose could be served by investigating the method at any greater length.

It is not claimed that the best method of administration of this prophylactic was used in these experiments It did seem possible that two large doses given at a short interval might approximate, in their behaviour, to the relatively protracted stimulus afforded by an adsorbed toxoid such as A P T, though it was realised that both these first doses would be subject to rather rapid loss from the body However, as we wanted to obtain information as rapidly as possible about the behaviour of this F T, the fortnight interval between the first and second doses was adopted in the initial investigations Work now in hand is directed to finding out what results are obtainable from two 0 5 ml doses of F T given at an interval of a month, the post-Schick tests being performed 3 months later The preliminary results are encouraging

It may also be that the results in table V are rather flattered by the fact that the Schick tests were made only a month after the last injection In the case of the three injection procedure, this need give rise to no apprehension that the method is not sound Past experience has shown that all modes of inoculation which produce a high Schick conversion rate, whatever the circumstances, also show good durability of immunity at long range An example of this is available (Bousfield 1947b)

Here it should be noted that complaints of objectionable local reaction following the subcutaneous inoculation of small Schick positive children with F T have been practically absent The use of this material in older persons would have to be the subject of a further inquiry In children there is absence of the subcutaneous nodule such as often follows the injection of prophylactics containing any form of aluminium compound at present in use

One more weapon is thus added to the armoury of those desirous of continuing diphtheria prophylaxis in all circumstances Three injections of F T in buffered saline solution, used in the dosage of 0 5 ml, and probably best at monthly intervals, can be given with excellent immunological results, without producing undesirable reactions Perhaps even two monthly injections of this prophylactic will suffice, but this remains to be seen Whatever method is adopted, it is necessary that it shall yield a high Schick conversion rate Among the last 5–10% of persons who are difficult to immunise are to be found just those most likely to contract the disease severely if attacked by it, especially if antitoxin treatment is delayed

EXPERIMENTAL DIPHTHERIA PROPHYLACTIC

To make immunisation of the very young infant as efficient as possible, it is necessary to consider the findings of Vahlquist (1949) and those of Barr et al. (1950) regarding a difficulty which may be encountered Their various observations showed that an occasional child, having a fairly large amount of residual maternally bestowed antitoxin in its blood, proved relatively difficult to immunise, or responded to injections only tardily It seems that the infant's antitoxin swamps the injected toxoid

I think it likely that this difficulty can be overcome by the use of a powerful and appropriately constituted prophylactic To this end a new type of material has been envisaged, and some early work with it is mentioned at this stage in the hope that the conception may appeal to other investigators, and thus provide information in the near future It would take a lone worker a long time to produce adequate evidence

It seems that one method of disposing of the undesirable passive immunity of an infant would be to inject a fairly large dose of F T This should fix the child's antitoxin by combining with it rapidly If, therefore, at the same time as the F T is injected, adsorbed toxoid (P T A P) were introduced, the latter might be left free to exercise its more potent stimulus unhampered Any T A.F formed from the combination of the child's antitoxin with the F T might even be helpful to a slight degree

A reasonable composition for such a prophylactic seemed to be 100 Lf units of fluid toxoid and 25 Lf units of P T A P contained in 1 ml Holt kindly prepared this material to the above specification in the Wright Fleming Institute of Microbiology, and a method has been found which ensures that a reasonable proportion of the F T remains unadsorbed on to the phosphate A good abbreviation for this experimental prophylactic would appear to be F P T (fluid and phosphate toxoid). Preliminary work on this prophylactic has been in progress, in the first instance on known Schick positive infants, to study its immunising properties

In theory F P T should prove excellent as a primary and secondary stimulus, because it possesses optimal characteristics for both purposes

At the time of writing, 154 children, mostly aged only a few months, have been treated with a single subcutaneous injection of 0 5 ml of the material Schick tests a month later showed only two positive readings, both very faint, a conversion rate of 98 7% Only by study of the effect of single injections can the merits of a prophylactic be determined with any degree of accuracy No attempt is made to produce evidence that one injection will suffice In practice the 0 5 ml. dose should be followed by a secondary stimulus some months later This could consist of 0 5 ml of F P T or F T

The main investigation is somewhat different Primarily Schick negative infants of tender age are being treated with a single subcutaneous dose of F P T, and this is not being augmented by a secondary stimulus The post Schick tests on these children will not be done before they reach the age of 1 year Comparison of the results, when available, with the normal expectations and trends, as shown in fig 3, will afford a fairly good indication of the success or failure of the procedure

Yet another group of Schick negative infants is being treated with a single 0 5 ml injection of F P T, by the subcutaneous route, followed by a secondary stimulus of 25 Lf units some months later The post Schick tests will be done at the age of 1 year, as in the former group From other experiences it is confidently anticipated that this method will yield good results

No untoward results have been encountered in the subcutaneous use of F P T, but it is advisable to warn parents that a very small lump will come under the skin, that this is quite normal, and that there is nothing to worry about If this is done, no complaints at all are received

If any other seekers after knowledge are interested in cooperating in these investigations on tiny infants, using F P T, Mr L B Holt, of the Wright Fleming Institute of Microbiology, will be glad to furnish them with a supply

GENERAL REMARKS AND CONCLUSIONS

It is felt that one logical approach to the solution of the problem of post injection paralysis is to inoculate infants subcutaneously with suitable diphtheria prophylactics as early as possible in life, and certainly before the age of 6 months On the basis of work so far completed, F T in buffered saline solution, as three injections of 0 5 ml each at monthly intervals, should be an adequate treatment for small infants Alternatively, two well spaced subcutaneous injections of P T A P 0 3 ml should suffice A fairly long interval between the injections is probably best—up to 3 or 4 months—if infants are inoculated when extremely small, without preliminary Schick tests Such procedure is likely to be more effective in the small percentage of infants who are treated initially while they still possess maternally bestowed antitoxin in their blood

No mention has been made here of whooping cough prophylaxis Assessment of its value must await the results of extensive investigations undertaken by the Medical Research Council Nevertheless the demand for the treatment by the public is such that the matter cannot be ignored by any authority Combined prophylaxis constitutes an admirable bait for diphtheria immunisation, and many only accept this latter treatment to procure whooping cough injections But whooping cough or combined prophylaxis will have to be the subject of a separate inquiry

Finally, though it is admitted that only time can prove how correct are the conclusions reached above, I submit that the suggested approach is rational and worthy of an extensive trial Only by continued constructive thought and effort can the question of post injection paralysis be answered

SUMMARY

It is shown that poliomyelitis, in recognisable form, seems to occur much less often in the first months of life than in the next few years of childhood

As the risk of post-injection paralysis is probably proportional to the liability to contract poliomyelitis, it is suggested that immunisation against diphtheria should be undertaken as early as possible in life—e.g., at the age of 2–5 months

Evidence is offered that infants can be immunised successfully at this age, and that the immunity holds good some 18 months to 2 years later in the great proportion of cases

The primary Schick state of 2781 infants has been studied to determine the percentage possessing natural protection against diphtheria at each age from 2–12 months It has been shown that active immunity can be procured in 98 9% of Schick-positive infants by about the 6th or 7th month of life

For the present it seems advisable to avoid intramuscular injections of diphtheria prophylactics, and to adopt the strictly subcutaneous route In an experience covering a very large number of injections, there have been no paralytic sequelæ, even throughout danger periods, when diphtheria antigens have been administered under the skin

Holt's P T A P, given as two subcutaneous injections of 0 3 ml. at a monthly interval, to children aged 1 year or less, has yielded a Schick conversion rate of 99 7%, without the production of objectionable reactions

The behaviour of a highly purified toxoid in buffered saline solution has been investigated, and further work is in progress on this material Given as three subcutaneous injections of 0 5 ml, it has produced a Schick conversion rate of 99 2 in children aged 1 year or less

An experimental diphtheria prophylactic (F P T) is described It is hoped that this material will enable infants with excessive amounts of antitoxin of maternal origin to be actively immunised effectively Collaboration in this investigation is sought 154 small children, all initially Schick positive, showed a conversion rate of 98 7% a month after a single subcutaneous injection of 0 5 ml of the material

Prophylactics at present generally available, which should prove suitable for subcutaneous administration to infants aged 2–5 months, are fluid toxoid (purified toxoid in buffered saline solution) as three monthly injections of 0 5 ml., or two well spaced injections of 0 3 ml of P T A P In treating infants who have not been previously shown to be Schick-positive an interval of 3 or 4 months between the two injections of P T A P is advised

Thanks are due to Dr A. A. Anderson (medical officer, No 9 Middlesex Area) for many facilities and helpful discussion, to Dr V Russell, D M O, No 1 London Division, Dr H D Chalke, D M O, No 7 London Division, and Dr W H S Wallace, D M O, No 8 London Division, for many facilities, to Mr L B Holt, of the Wright-Fleming Institute of Microbiology, for the preparation of special antigens, to the General Register Office for investigating the incidence of poliomyelitis in infants during the first three quarters of 1950, to the numerous medical officers of health throughout the country who have given me information and statistical evidence, and finally to Sir Allen Daley (medical officer of health, London County Council) whose chance remark was responsible for the production of much of this evidence

THE BACTERIOSTATIC EFFECTS OF THE NEWER DRUGS IN THE TREATMENT OF GENITO-URINARY TUBERCULOSIS

A REVIEW OF 51 CASES

ROYAL SOUTHERN HOSPITAL, LIVERPOOL

> I hope I grow wiser every year —John Hunter.

The effects of streptomycin and other substances, both alone and in combination, on tuberculosis of the genito urinary tract have been investigated. The following drugs were used

(1) Streptomycin alone in a dosage of 0·5 g b d. up to a total of 90 g

(2) Streptomycin and para aminosalicylic acid (P.A.S) together, streptomycin 0·5 g b d up to a total dosage of 90 g, and P.A.S 15 g daily

(3) Streptomycin and P.A.S alternately for six months, each being given for a month alone, streptomycin 0·5 g b d., and P.A.S 15 g daily

(4) Streptomycin and P.A.S alternately as in (3) plus thiacetazone (‘Thioparamizone’) 50 mg daily to begin with and gradually increasing to 200 mg daily, the whole course lasting six months.

The genito urinary tuberculosis was divided into five types (the classification suggested by the Medical Research Council)

(1) An early unilateral lesion of the renal parenchyma.

(2) A unilateral renal lesion with cystitis and nephrectomy

(3) A bilateral renal lesion with nephrectomy of the worse kidney

(4) Cystitis and involvement of the remaining kidney after nephrectomy

(5) Major bilateral severe disease

All the patients were treated at Wrightington Sanatorium, and were kept for several months under a strict sanatorium régime The diagnosis depended entirely on the isolation of tubercle bacilli from the urine by cultural methods, or by guineapig inoculation The urine was repeatedly examined, but one of the major difficulties was the inability to demonstrate tubercle bacilli either by culture or by guineapig inoculation once the course of treatment had begun.

Cystoscopy and bilateral retrograde pyelography were done whenever possible, and the urine from each kidney was cultured and inoculated into guineapigs The capacity of the bladder was estimated at each cystoscopy and intravenous pyelography was repeated at three-month intervals A close watch was kept for toxic manifestations

ASSESSMENT OF IMPROVEMENT

We consider that certain basic principles should be emphasised at the outset First, in our present state of knowledge, we should not speak of a cure of tuberculosis but merely control of the disease Follow up investigations have not been made for a sufficiently lengthy period, and the number of relapses which are occurring now will almost certainly tend to increase during the succeeding years Secondly, we have no accurate knowledge yet of the precise action of streptomycin and the other drugs on the tubercle bacillus Thirdly, resistance of the organisms may develop very rapidly, particularly in an acid medium Lastly, resistance of the human body must play a large part in the action against the tubercle bacillus, but to what extent as yet remains unsolved It is an undoubted fact that some patients seem to carry on for many years without any sanatorium or specific treatment One of us (J C R) sees at six month intervals a patient in whom bilateral renal tuberculosis was diagnosed thirteen years ago, after the organism had been obtained from each ureter after ureteric catheterisation The patient has steadfastly refused any treatment but is apparently well, except for frequency of micturition

An attempt has been made to assess progress under the following headings

(1) Micturition (*a*) alteration in frequency, (*b*) presence or absence of pain during micturition.

(2) Cystoscopic appearances of the bladder

(3) Alteration in capacity of the bladder

(4) Sterilisation of the urine

(5) Alteration in intravenous or retrograde pyelograms.

STREPTOMYCIN ALONE

So much has already been published about the pharmacology, dosage, efficiency, and toxicity of streptomycin that it is enough for us to say that the total dosage in this series was 90 g given as 0·5 g b d. for ninety consecutive days, and that the urine was made alkaline before treatment with streptomycin was begun, and was kept so throughout the course of treatment We were particularly careful to keep the urine alkaline throughout the course because streptomycin resistance appears more rapidly in an acid medium, and sometimes appears within a few days (Finland et al. 1946, Harris et al. 1947) One of our great difficulties was to keep the urine alkaline, even after large doses of potassium citrate the urine occasionally remained neutral.

The results are shown in table I and are similar to those obtained by Jacobs and Borthwick (1950) and Lattimer (1948) and Lattimer et al. (1949) In none of the severe cases was there sufficient improvement to allow surgery Streptomycin seemed to have some effect on the cystitis, but this usually depended on removal of the primary focus

STREPTOMYCIN AND P.A.S TOGETHER

In view of these poor results, and of the fact that it was considered at that time undesirable to increase the dosage of streptomycin owing to possible toxicity, it was decided to use a combination of streptomycin and P.A.S Table II shows the results thus obtained.

STREPTOMYCIN AND P.A.S ALTERNATELY

At this stage of our investigation we had great difficulty in giving P.A.S and potassium citrate together, because of the tendency to nausea and vomiting We felt that since it was important to keep the urine alkaline during streptomycin therapy, we should try some other method, and decided to administer streptomycin and P.A.S alternately, giving the potassium citrate at the same time as the streptomycin. In support of this we knew that streptomycin resistance increased rapidly after 30 g had been given (M. E Florey, personal communication) No case of streptomycin resistance in an alkaline medium has been reported in less than 28 days, when streptomycin had been given at the rate of 1 g a day, on the other hand, 30% were resistant after 42 g had been given, and 60% were resistant after 60 g Further support of this method of treatment was afforded by Cayley's (1950) report of serum potassium deficiency following protracted administration of P.A.S

Table III shows the results of cases treated by this method

STREPTOMYCIN, P.A.S, AND THIACETAZONE

After considering these results we were still dissatisfied, although there appeared to be slight improvement with alternate streptomycin and P.A.S We therefore tried

In theory F P T should prove excellent as a primary and secondary stimulus, because it possesses optimal characteristics for both purposes

At the time of writing, 154 children, mostly aged only a few months, have been treated with a single subcutaneous injection of 0 5 ml of the material Schick tests a month later showed only two positive readings, both very faint, a conversion rate of 98 7% Only by study of the effect of single injections can the merits of a prophylactic be determined with any degree of accuracy No attempt is made to produce evidence that one injection will suffice In practice the 0 5 ml dose should be followed by a secondary stimulus some months later This could consist of 0 5 ml of F P T or F T

The main investigation is somewhat different Primarily Schick-negative infants of tender age are being treated with a single subcutaneous dose of F P T, and this is not being augmented by a secondary stimulus The post-Schick tests on these children will not be done before they reach the age of 1 year Comparison of the results, when available, with the normal expectations and trends, as shown in fig 3, will afford a fairly good indication of the success or failure of the procedure

Yet another group of Schick negative infants is being treated with a single 0 5 ml injection of F P T, by the subcutaneous route, followed by a secondary stimulus of 25 Lf units some months later The post Schick tests will be done at the age of 1 year, as in the former group From other experiences it is confidently anticipated that this method will yield good results

No untoward results have been encountered in the subcutaneous use of F P T, but it is advisable to warn parents that a very small lump will come under the skin, that this is quite normal, and that there is nothing to worry about If this is done, no complaints at all are received

If any other seekers after knowledge are interested in cooperating in these investigations on tiny infants, using F P T, Mr L B Holt, of the Wright-Fleming Institute of Microbiology, will be glad to furnish them with a supply

GENERAL REMARKS AND CONCLUSIONS

It is felt that one logical approach to the solution of the problem of post injection paralysis is to inoculate infants subcutaneously with suitable diphtheria prophylactics as early as possible in life, and certainly before the age of 6 months On the basis of work so far completed, F T in buffered saline solution, as three injections of 0 5 ml each at monthly intervals, should be an adequate treatment for small infants Alternatively, two well spaced subcutaneous injections of P T A P 0 3 ml should suffice A fairly long interval between the injections is probably best—up to 3 or 4 months—if infants are inoculated when extremely small, without preliminary Schick tests Such procedure is likely to be more effective in the small percentage of infants who are treated initially while they still possess maternally bestowed antitoxin in their blood

No mention has been made here of whooping cough prophylaxis Assessment of its value must await the results of extensive investigations undertaken by the Medical Research Council Nevertheless the demand for the treatment by the public is such that the matter cannot be ignored by any authority Combined prophylaxis constitutes an admirable bait for diphtheria immunisation, and many only accept this latter treatment to procure whooping cough injections But whooping cough or combined prophylaxis will have to be the subject of a separate inquiry

Finally, though it is admitted that only time can prove how correct are the conclusions reached above, I submit that the suggested approach is rational and worthy of an extensive trial Only by continued constructive thought and effort can the question of post injection paralysis be answered

SUMMARY

It is shown that poliomyelitis, in recognisable form, seems to occur much less often in the first months of life than in the next few years of childhood

As the risk of post injection paralysis is probably proportional to the liability to contract poliomyelitis, it is suggested that immunisation against diphtheria should be undertaken as early as possible in life—e.g, at the age of 2–5 months

Evidence is offered that infants can be immunised successfully at this age, and that the immunity holds good some 18 months to 2 years later in the great proportion of cases

The primary Schick state of 2781 infants has been studied to determine the percentage possessing natural protection against diphtheria at each age from 2–12 months It has been shown that active immunity can be procured in 98 9% of Schick-positive infants by about the 6th or 7th month of life

For the present it seems advisable to avoid intramuscular injections of diphtheria prophylactics, and to adopt the strictly subcutaneous route In an experience covering a very large number of injections, there have been no paralytic sequelæ, even throughout danger periods, when diphtheria antigens have been administered under the skin

Holt's P T A.P, given as two subcutaneous injections of 0 3 ml at a monthly interval, to children aged 1 year or less, has yielded a Schick conversion rate of 99 7%, without the production of objectionable reactions

The behaviour of a highly purified toxoid in buffered saline solution has been investigated, and further work is in progress on this material Given as three subcutaneous injections of 0 5 ml, it has produced a Schick conversion-rate of 99 2 in children aged 1 year or less

An experimental diphtheria prophylactic (F P T) is described It is hoped that this material will enable infants with excessive amounts of antitoxin of maternal origin to be actively immunised effectively Collaboration in this investigation is sought 154 small children, all initially Schick positive, showed a conversion rate of 98 7% a month after a single subcutaneous injection of 0 5 ml of the material

Prophylactics at present generally available, which should prove suitable for subcutaneous administration to infants aged 2–5 months, are fluid toxoid (purified toxoid in buffered saline solution) as three monthly injections of 0 5 ml., or two well spaced injections of 0 3 ml of P T A P In treating infants who have not been previously shown to be Schick-positive an interval of 3 or 4 months between the two injections of P T A.P is advised

Thanks are due to Dr A A. Anderson (medical officer, No 9 Middlesex Area) for many facilities and helpful discussion, to Dr V Russell, D M O, No 1 London Division, Dr H D Chalke, D M O, No 7 London Division, and Dr W H S Wallace, D M O, No 8 London Division, for many facilities, to Mr L B Holt, of the Wright-Fleming Institute of Microbiology, for the preparation of special antigens, to the General Register Office for investigating the incidence of poliomyelitis in infants during the first three quarters of 1950, to the numerous medical officers of health throughout the country who have given me information and statistical evidence, and finally to Sir Allen Daley (medical officer of health, London County Council) whose chance remark was responsible for the production of much of this evidence

TABLE V—STERILISATION OF URINE

Treatment	No of cases	Result
Streptomycin alone	18	13 became and remained sterile 3 remained persistently positive 2 became initially sterile but reverted to positive later
Streptomycin and P.A.S together	7	4 became and remained sterile, 1 remained positive 2 became initially sterile but reverted later
Streptomycin and P.A.S alternately	20	19 became and remained sterile 1 remained constantly positive no reversions occurred up to six months after cessation of treatment
Streptomycin, P.A.S and thiacetazone	6	6 have remained sterile up to date

Comparison Between the Four Groups—Treatment groups 3 and 4 seemed to offer the best promise of success Although the severe lesions were disappointing in their response to any method of treatment, there was some improvement in group 4 Seven cases of progressive hydronephrosis were encountered in the whole series Of these, one was in group 1, two in group 2, two in group 3, and two in group 4. This might possibly be taken to indicate that there is an increased fibrosis at the lower end of the ureter, brought about by healing, thus causing an increase in the hydronephrosis We have also found that cases in which hydronephrosis is present at the start of treatment rarely show any response in any of the four groups, and eventually require ureteric transplant into the colon

Comparison Between Single and Multiple Lesions—Out of 51 cases there were 26 in which the lesion seemed to be confined to the genito urinary tract, and 25 in which it was an incident in a generalised disease affecting other systems of the body There has been no significant difference between the response to treatment in the two divisions

Comparison Between the Five M.B.C Types—Type 1 seems to respond equally well to streptomycin alone and in combination Type 2, if anything, responds best to streptomycin and P.A.S given alternately Type 3 responds equally well to either of these methods of treatment Types 4 and 5 are disappointing, and are unpredictable in their response Treatment with the three drugs seems to be the most helpful in these advanced cases If hydronephrosis is present, however, the outlook is poor in any event

Sterilisation of Urine—The results are given in table V

Intravenous Pyelograms—The results are given in table VI.

SURGICAL TREATMENT

Nephrectomy has been done in twenty-two cases in this series, always under a "screen" of streptomycin In no case was the wound drained, and it is not our practice to remove the lower end of the ureter With this technique all the cases healed by first intention, and so far it has not been necessary to remove the lower end of the ureter later We believe that, provided there is adequate drainage of the ureteric stump into the bladder the ureter ultimately heals, becoming a solid fibrous cord The type of ureter which may require excision is the tortuous fixed indurated one that does not drain freely We deprecate the common practice of doing a nephrectomy for tuberculosis at a general hospital, and subsequently transferring the patient to a sanatorium for continuation of treatment The nephrectomy is a single, although a most important, incident in the treatment of a generalised disease, and requires careful timing if primary healing is to be achieved in every case

Epididymectomy was done on many occasions by Ross's (1948) technique The scrotum was not drained, and all the wounds healed by first intention We suggest that a tuberculous epididymis may lead to the appearance of tubercle bacilli in the urine, and that, until this source has been removed, it is impossible to be certain that a subclinical focus is present in either kidney The prostate gland has been massaged before and after epididymectomy, and in four cases the urine, which contained tubercle bacilli before the operation, has remained persistently sterile after epididymectomy

Ureteric transplant has been done on eight patients three by the extraperitoneal technique, and five by Cordonnier's (1949) intraperitoneal method There was no immediate postoperative mortality, but the former three patients (in each of whom the ureter of a remaining kidney was transplanted) died of uræmia within six months Of the latter five patients two died eight weeks after operation with an ascending infection, both of them had had the ureter of a solitary kidney transplanted and had severe cystitis and a contracted bladder The three other patients were well and improved after operation, the hydronephrosis being much reduced in size

Ureters were transplanted for (1) increasing hydronephrosis, (2) severe cystitis and contracted bladder, (3) severe intractable frequency of micturition, and (4) tuberculous stricture of the urethra

In view of the report by Baggenstoss (1949) that streptomycin does not penetrate the fibrous wall, and hence does not enter the cavities, of ulcero cavernous lesions—we tried to grow cultures of tubercle bacilli from the pus of cavities after nephrectomy, which was done always towards the end of the treatment period If we were successful, the organism was tested for sensitivity or resistance to streptomycin The streptomycin content of the pus from which these bacilli were obtained was also estimated.

TABLE VI—INTRAVENOUS PYELOGRAMS

Treatment	No of cases	Result
Streptomycin alone	18	15 remained unchanged 3 deteriorated 1 showing hydronephrosis and 2 involvement of more calyces
Streptomycin and P.A.S together	7	4 remained unchanged 3 deteriorated 2 showing increase in hydronephrosis and 1 involvement of additional calyces
Streptomycin and P.A.S alternately	20	16 remained unchanged 2 deteriorated both showing increase in hydronephrosis, 1 hydronephrosis improved 1 showed healing of an ulcero-cavernous lesion
Streptomycin, P.A.S and thiacetazone	6	4 unchanged 2 deteriorated, showing increase in hydronephrosis

The results (table VII) are discouraging, and only in case 13 could we grow a tubercle bacillus sensitive to a lower percentage of streptomycin than was present in the pus The resistant organisms were resistant to concentrations of streptomycin much in excess of those we found in the cavities, the greatest being 8 5 units per ml. in case 3 Probably the reason for this is the acidity of the pus which predisposes to the rapid emergence of a resistant strain of bacillus It is significant, however, that some streptomycin does penetrate the walls of the cavities

The variation in concentration is unexplained at present, but it may depend on the timing of the nephrectomy in relation to the last injection of streptomycin

It is also important to ascertain whether there is any difference in sensitivity between the organisms in the urine and those located etazone in conjunction with streptomycin and Since all three drugs may exercise their effect e tubercle bacillus in a different manner, it seemed l to assume that a combination of all three might ice better results

e thiosemicarbazone drugs, discovered in 1946, shown by Domagk et al (1946) to be active against ubercle bacillus, and have been extensively studied ermany since then In vivo experiments have n that some of them have a suppressive action on rowth of this organism Their action is apparently effective than that of streptomycin, but more ive than that of P A S (Donovick 1949) Toxic ions may develop, the commonest being anorexia, ea, vomiting, agranulocytosis, and hæmolytic ia Such reactions are relatively infrequent, ded the dose does not exceed 200 mg a day

haw and McDermott (1950) and Mertens and e (1950), summarising the extensive clinical trials rmany, reported that about 70% of lesions through he body were improved They issued a warning, ver, that these results were obtained against ng nutritional and social standard According to these workers, the cases responding most favourably were those in which the infection was confined to mucosæ—i e, tracheobronchitis, bronchitis, laryngitis, enteritis, and cystitis They thought that thiosemicarbazone was *not* sufficiently powerful by itself, but that in combination with other drugs it might prove of value in the treatment of tuberculosis In the German investigation few cases of genito urinary tuberculosis were included Hurni (1949) studied the effects in vivo of various combinations of thiacetazone, streptomycin, and P A S He showed that, though combinations of thiacetazone with P A S, and of thiacetazone with streptomycin, had no additive effect, combinations of all three drugs in therapeutic doses had some increased effect in mice So far we have only treated six cases by the combined method, but all the patients concerned showed encouraging improvement, although falling into the most severe type of case

Table IV shows the results in this small group

DISCUSSION OF RESULTS

We emphasise again that the final results of treatment can only be assessed after many years

TABLE I—RESULTS OF THERAPY WITH STREPTOMYCIN ALONE

C e	No of cases	Clinical improvement		Bladder		Sterilisation of urine	Intravenous pyelographic changes	Remarks
		Frequency of micturition	Pain on micturition	Appearance	Capacity			
	1	1 improved	1 improved	1 no change	1 no change	1 sterile	1 no change	
	7	5 improved (1 slight)	5 improved	4 improved	5 improved	5 sterile 1 constantly positive, 1 initially sterile but reverted later	7 no change	
	2	2 improved	2 improved	2 improved	2 improved	2 sterile	2 no change	
	4	4 improved (2 slight)	4 improved (2 slight)	1 improved 3 no change	1 improved 3 no change	3 sterile, 1 initially sterile, but reverted later	2 no change 2 deteriorated	The case which showed cystoscopic improvement deteriorated later despite treatment
	4	2 improved (slight) 2 no change	3 improved 1 no change	3 no change 1 deteriorated	3 no change 1 deteriorated	2 sterile, 2 remained positive	3 no change, 1 deteriorated, increase in hydronephrosis	

TABLE II—RESULTS OF THERAPY WITH STREPTOMYCIN AND P A.S TOGETHER

1	1 improved	1 improved	1 improved	1 improved	1 sterile	1 no change	
2	2 improved	2 improved	2 improved	2 improved	1 sterile, 1 initially sterile but reverted later	2 no change	
2	1 no change 1 deteriorated	1 no change 1 deteriorated	2 no change	2 no change	1 positive, 1 initially sterile but reverted later	2 deteriorated	Both showed increased hydronephrosis and had ureteric transplantation into the bowel
2	1 improved slightly 1 no change	2 improved	1 improved 1 no change	1 improved 1 no change	2 sterile	1 no change 1 deteriorated	

TABLE III—RESULTS OF THERAPY WITH STREPTOMYCIN AND P A.S ALTERNATELY

6	6 improved	6 improved	6 no change	6 no change	6 sterile	1 improved 5 no change	This case showed healing of an ulcerocavernous lesion
7	7 improved	7 improved	5 improved 2 no change	5 improved 2 no change	7 sterile	7 no change	
3	3 improved	3 improved	1 improved 2 no change	1 improved 2 no change	3 sterile	2 no change 1 deteriorated	Increase in hydronephrosis
4	3 improved 1 deteriorated	3 improved 1 deteriorated	2 improved 1 no change	2 improved 1 no change	3 sterile, 1 consistently positive	1 improved 2 no change 1 deteriorated	This improvement was manifested by a decrease in hydronephrosis the deterioration was an increase in hydronephrosis

TABLE IV—RESULTS OF THERAPY WITH STREPTOMYCIN, P.A S, AND THIACETAZONE

1	1 improved	1 improved	1 improved	1 improved	1 sterile	1 deteriorated	Increase in hydronephrosis
5	3 improved 2 no change	3 improved 2 no change	4 improved 1 deteriorated	4 improved 1 deteriorated	5 sterile	4 no change 1 deteriorated	Increase in hydronephrosis

melæna. He had about six months' history of upper abdominal discomfort after meals and some loss of appetite.

On admission he had collapsed after severe melæna, and his hæmoglobin was 46%.

Treatment and Progress.—Under treatment, including blood transfusion, he improved. Recurrence of bleeding called for a further transfusion of 2 pints of blood on June 10, after which he again improved till June 15, when at 9.30 A.M. he had severe upper abdominal pain and was once again collapsed and pale. His hæmoglobin was then 60%. Abdominally he was a typical case of perforated peptic ulcer. In view of the bad prognosis of the combination of perforation and hæmorrhage from gastric ulcer I felt that suture of the perforation alone held very little hope of recovery, and I decided on partial gastrectomy, after restorative measures, which lasted four hours. This seemed a very hazardous undertaking in a patient so ill, but I thought the risk justifiable. Gastric suction was instituted, 3 pints of blood was given, and morphine gr $^{1}/_{2}$ and atropine gr $^{1}/_{100}$ were injected as premedication.

At operation free gas and much free fluid was found in the abdomen. A perforated ulcer was present on the anterior wall of the stomach $2^{1}/_{2}$ in from the pylorus and just off the lesser curve. The perforation was rapidly closed, and the free fluid removed by suction. There was nothing in the appearance of the ulcer to suggest that it was not benign. A partial gastrectomy was done rapidly but it had to be a high one because of a second ulcer high on the posterior wall adjacent to the lesser curve. This ulcer I suspected of being the source of the hæmorrhage. The abdomen was closed without drainage. A blood drip had been continued throughout the operation, and the anæsthetic (thiopentone, gas oxygen, and curare), given by Dr J. Piney, caused so little upset that the general condition of the patient had improved when he left the operating theatre.

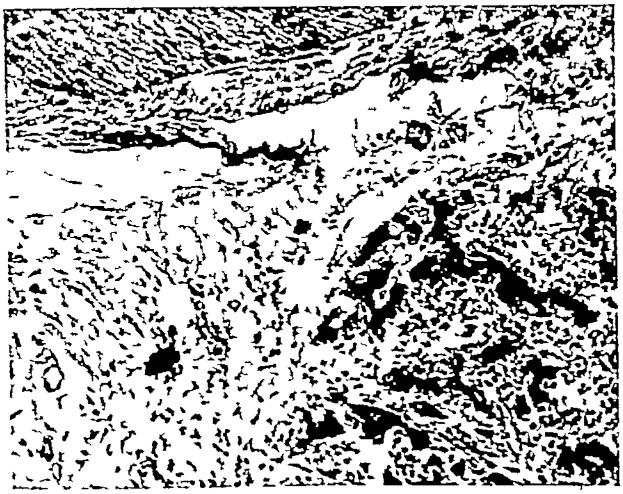

Fig. 2 (case 1)—The floor of the ulcer at the extremity of invasion by carcinoma cells at the level of the artery seen in fig 1. The wall of this artery can be seen at the top of the figure, the carcinoma cells at the right, and the fibrous tissue of the floor of the pre-existing ulcer on the left (× 100)

Postoperative Treatment and Progress.—Chemotherapy was given and a further 2 pints of blood and the patient's condition steadily improved. He was discharged on July 11, 1949, able to enjoy a normal diet. He returned from convalescence very fit, and when seen about a year later was in the best of health. On April 27, 1951, he was still in excellent health and working as a policeman in the R.A.F. constabulary.

Pathological Report (Dr M. O. Skelton).—'The stomach presents two chronic ulcers, one is 6 cm. proximal to the pylorus on the anterior surface, with one edge 3 mm. from the lesser curvature. This ulcer measured 2 × 1 cm., with the long axis longitudinally, and has perforated and been sutured with catgut. There is another ulcer, 5 cm proximal to the first, on the posterior wall 5 mm. from the lesser curvature. This ulcer measured 1·5 × ·5 cm. Microscopically the perforated ulcer from the anterior wall has a partially necrotic floor covered by granulation tissue overlying the muscularis, which shows fibrous replacement of some of the muscle tissue. There is a small artery in the floor of the ulcer plugged with fresh thrombus. At one edge of the ulcer the mucosal glandular epithelium has undergone malignant change, and short columns of poorly differentiated carcinoma cells are insinuating themselves between the muscle-bundles and the fibrous tissue strands of the ulcer, and are seen lying beneath its floor (figs 1 and 2). The malignant change appears to have begun at one end and to be sweeping across the ulcer from one side. Microscopic examination of the second ulcer (figs 3 and 4) shows a chronic peptic ulcer with undoubted carcinomatous change at both edges—groups of malignant cells are seen invading the stomach wall. A section across the mucosa between the ulcers shows chronic gastritis but no carcinoma cells. Lymph nodes from the left gastric group show no tumour invasion. There are two separate carcinomata developing in chronic gastric ulcers.'

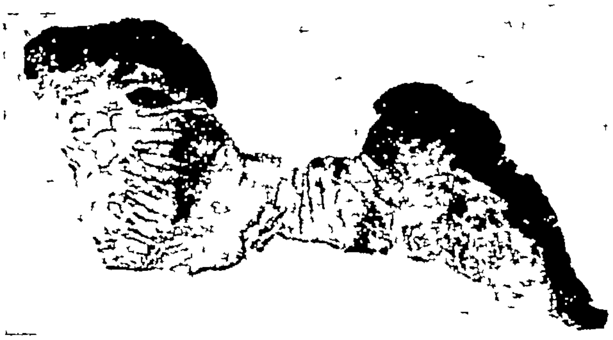

Fig 3 (case 1)—Ulcer on lesser curve of stomach showing the infiltration of the fibrous floor of the chronic gastric ulcer by carcinoma cells on the right. The infiltration has invaded the wall of the stomach fairly deeply but has not traversed it so extensively as in the ulcer shown in fig 1 (× 4)

The gratifying result in this desperately ill patient fully justified the formidable operation, and has convinced me that, for perforation after hæmorrhage, gastrectomy should be done if a skilled team and an able and experienced anæsthetist are available. The report of Mr W. J. Ferguson's two successful cases (Ives 1950) stimulated me to report this case in support of more radical measures for this grave condition.

The pathological report is of considerable interest because both ulcers were malignant and separated by a considerable area of stomach showing no malignant change. Two separate carcinomatous ulcers in one

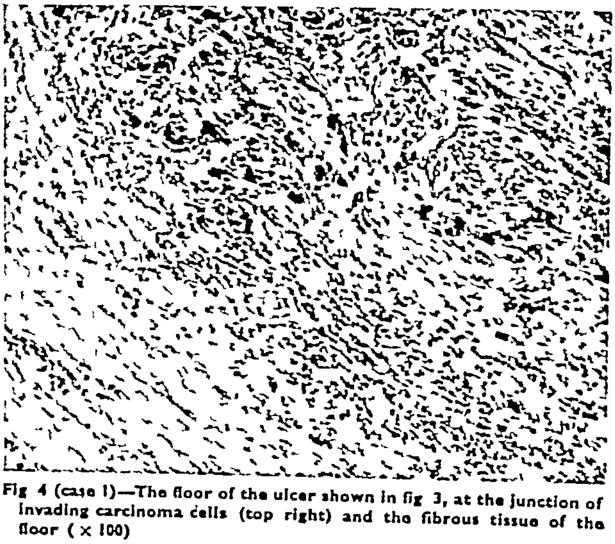

Fig 4 (case 1)—The floor of the ulcer shown in fig 3, at the junction of invading carcinoma cells (top right) and the fibrous tissue of the floor (× 100)

TABLE VII—CULTURES FROM PUS OF NEPHRECTOMY CAVITIES

Case no	Culture of tubercle bacillus isolated from pus in cavity	Sensitivity to streptomycin per ml	Streptomycin per ml of pus in cavities
1	Positive	Resistant to 64 u	None present no streptomycin for three weeks
2	Positive	Resistant to 64 u	5 u
3	Negative	Not estimated	8 5 u
4	Negative	Not estimated	4 u
5	Negative	Not estimated	None present, no streptomycin for four weeks
6	Positive	Resistant to 64 u	2 5 u
7	Positive	Sensitive to 8 u	2 u
8	Positive	Sensitive to 1 u	No pus
9	Positive	Sensitive to 1 u	No pus
10	Positive	Resistant to 64 u	No pus
11	Negative	Not estimated	3 5 u
12	Negative	Not estimated	2 u
13	Positive	Sensitive to 1 u	4 u
14	Negative	Not estimated	5 u
15	Positive	Resistant to 64 u	4 9 u

cavities Possibly the organisms excreted in the urine are sensitive to streptomycin, whereas those in the cavities (owing to the acidity) have become resistant The great difficulty of prosecuting this line of investigation is that, once the streptomycin course has been started, cultures of tubercle bacilli from the urine are difficult to obtain

CONCLUSIONS

In established cases of severe renal disease treatment with streptomycin alone seemed to have no apparent effect, except for some symptomatic improvement If the disease is unilateral nephrectomy remains the method of choice

Of the four treatment groups, group 4 seemed to give the most encouraging results

In M R C types 1, 2, and 3 the prognosis is good, in types 4 and 5 poor

The three drugs used are not substitutes for surgery, but will prove of value in combination with the usual surgical measures

The sanatorium régime is still an essential part of the treatment, and should be insisted on in every case

There is no significant difference in the results of treatment between those cases in which the genito urinary lesion is the only manifestation of the disease and those in which there are also lesions in other systems

Patients presenting initially with hydronephrosis respond badly, whatever the treatment, and usually require transplant of the ureter With the Cordonnier (1949) technique the hydronephrosis is definitely improved by operation

Surgery should always be done under a "screen" of streptomycin

Ureterectomy is not essential as a general rule

Calcification is no proof that the disease is inactive

The results of a preliminary investigation into the relation of the amounts of streptomycin in ulcero cavernous lesions to the sensitivity of the bacilli are discouraging

FUTURE POLICY

In view of the fact that more encouraging results have been achieved with streptomycin, P A S, and thiacetazone, we intend to use this treatment in all cases in future We have increased the dosage of streptomycin to 2 g a day (Lattimer et al 1949) and are using a possibly more active and less toxic thiosemicarbazone—i e, 'Ethizone' (Herts Pharmaceuticals Ltd.) Woody and Avery (1948) have shown the value of potassium iodide in increasing the effectiveness of streptomycin against the tubercle bacillus in laboratory animals and in pulmonary lesions We are therefore adding 5 g of potassium iodide to the alkaline mixture given as a routine during the administration of streptomycin

We wish to thank Dr J Dobson, superintendent and resident orthopædic surgeon, Wrightington Sanatorium, for his coöperation and keen interest, Prof A W Downie for his help with estimations of streptomycin sensitivity, and Herts Pharmaceuticals Ltd for technical assistance, and supplies of thioparamizone and ethizone

ASSOCIATED PERFORATION AND HÆMORRHAGE FROM UNSUSPECTED GASTRIC CARCINOMA

JAMES JEMSON

F R C S

CONSULTANT SURGEON, LEWISHAM HOSPITAL, LONDON

THE combination of perforation and hæmorrhage from gastric ulceration is rare (Ives 1950) and carries a very grave prognosis In twenty five years' surgical work in hospitals I have encountered several such cases and have been impressed by the fatal termination of most of them

Case 1, which came under my care on June 15, 1949, presented additional unusual features

Case 1 —A man, aged 52, was admitted to Lewisham Hospital on June 7, 1949 He had suddenly collapsed while having a drink three days previously and had subsequently had

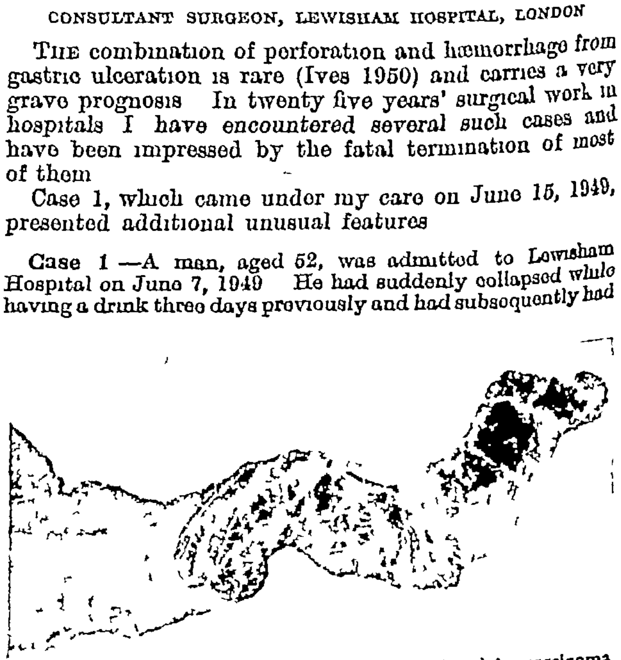

Fig 1 (case 1)—Ulcer in pyloric canal, showing dark staining carcinoma cells infiltrating the fibrous floor of the ulcer from the right. The malignant cells have traversed the floor of the ulcer as far as the large artery (× 4) possible, they still average about 50 a day No doubt similar conditions and a similar volume of work are to be found at most large hospitals in the country

Without large and extensive buildings and a very numerous and highly trained staff, major operating-theatre ritual for the treatment and dressing of wounds with such a volume of work is impossible In devising a practical method of treatment and dressing of wounds we *have to compromise* I have worked on the principle that cross infection from other patients is the most important factor to avoid, the organisms carried by the patient are considered to be of secondary importance in causing clinical infection of his wound To prevent cross infection it means that every instrument or pair of hands that touches one patient must be sterilised before it is used to dress the open wound of another patient

A no touch technique at first sight seems to be the answer to this, but I have yet to meet the person so dexterous with forceps that he can bandage a finger without touching the patient Washing the hands between each patient is a snare and a delusion Either the hands are washed so perfunctorily that the washing is of no value, or the hands become raw when many dressings have to be done, and cause infection on their own account To overcome this human element, in 1940, while serving in the Nigerian Medical Service, I devised an "assembly line" or "mass production" routine for doing dressings When I returned to Leeds to take charge of the casualty department, this method was introduced with only such modifications as the better equipment allowed

"ASSEMBLY LINE" ROUTINE

The routine now carried out in Leeds for dressings is as follows When the patient returns for a dressing, as he enters the department the old dressing is removed and a temporary dressing of sterile gauze is applied to the wound The patient holds this in place and walks over to the bench at the side of the casualty surgeon's table The patient lifts up the gauze, the surgeon inspects the wound, and the gauze is immediately replaced The surgeon records progress on a chart Tickets describing the dressing to be used and any other after treatment are given to the patient, who then passes behind a screen to the dressing team The tickets, each of which is of a different colour for each different treatment, are a great help in reducing contact between patient and dresser, for the dresser soon learns the significance of the different colours and can see at a glance what is required without having to read a card

The dressing team basically consists of three people—the server, dresser no 1, and dresser no 2 As the patient comes into the dressing line he sits down opposite dresser no 1, and as he does so the server places a sterile kidney dish, containing three pairs of forceps, pledgets of wool, and gauze dressing, on the table in front of the dresser With one pair of forceps the dresser removes the temporary dressing, and this pair of forceps is then discarded. With the remaining two pairs, one in each hand, the dresser swabs the wound with 1% cetrimide and places the next dressing on the wound The wound now being covered, the patient holds the dressing in place and moves down the bench to dresser no 2, who bandages the hand Meanwhile the server has removed the soiled kidney dish used for the first patient, and produces a new set of instruments as the next patient moves into place opposite dresser no 1 The soiled kidney dish of instruments is placed in the steriliser for use in turn later

It was found that patients with many stitches to be removed caused some delay to the main stream They were therefore diverted to dresser no 1a, who received from the server a standard set of instruments plus scissors, with which he cleaned the wound and removed the stitches, again using a no touch technique The patient then returned to the main stream for a bandage to be applied Often two dressers no 2 were required to do the bandaging so that no delay occurred after the dressing had been applied The server, usually the junior sister, was in charge of the team The dressers were from the general surgical firms, coming in teams of three, each team coming about once in 10 days Once they had learnt this routine, the teams became very quick in dressing, and, subject to the critical eye of the sister, there was a certain amount of competition The "prize" went to a team of three dressers and a nurse who did 45 dressings in 45 minutes This rapidity alone is a great help in preventing air contamination of the exposed wound, but, apart from this, it will be observed that no one handles the patient until the wound is covered, and so there was no need for dresser no 1 to wash his hands between each case When dresser no 2 bandages the patient, the wound is already covered, and so there is little chance of cross infection from this dresser's hands, and again there is no need for dresser no 2 to wash his hands between each case

The rapidity which the early morning dressing queue is disposed of also reacts on the efficient initial treatment of lacerations. The wounds are almost entirely sutured by the student dressers Therefore, as the wounds come in during the day, the students are free to proceed with them with the smallest possible delay On arrival in casualty the wounds are cleaned with 1% cetrimide Originally we used swabs for this, but now we use a soft 'Nylon' pastry brush Commonly we leave the patient to clean the wound and the surrounding skin by himself The arbitrary time of 10 minutes is fixed so that all the grease and dirt which may be present in the factory injuries can be adequately removed The wound is next inspected by the casualty officer, who grades it according to the amount of laceration and/or contamination (see figure) and possibly advises

stomach must be very rare, and the complications of hæmorrhage from one ulcer and perforation of the other is even rarer

It is known that malignant cells may become implanted in a suture line after conservative resection of the rectum, but this patient had not had any previous surgical interference, and so I do not think there is any parallel here, especially since the lower ulcer showed a more extensive infiltration by malignant cells than did the upper one If grafting of malignant cells had taken place, it might be reasonable to suggest that it took place from the lower ulcer to the upper one In the stomach this is theoretically possible if malignant cells can survive after detachment in the gastric juices My feeling in this case is that, with a more advanced stage of malignancy in the lower ulcer, grafting of malignant cells, though possible, is unlikely

This case lends support to Doll's (1950) warning that a gastric ulcer which perforates may not be a simple ulcer, and that if the patient is over 40 years of age he should be kept under observation Some cases of perforated carcinomatous ulcers are fairly easily recognised, but the fact that in 7 of 86 male cases reported by Doll (1950) a carcinoma was present in the stomach within three years after perforation confirms the view that a malignant ulcer may perforate long before it is possible to recognise it as malignant at operation

It was only the combination of perforation and hæmorrhage that decided me to undertake a gastrectomy and so incidentally gave the patient a much greater chance of cure from a deadly disease which otherwise might only have come to light much later when definitely incurable

Two other cases operated on by me have impressed on me the necessity of a careful follow up of cases of perforation One should submit them to early gastrectomy if suture of the perforation is not followed by complete relief from symptoms

Case 2 —A man, aged 66, had a prepyloric ulcer which perforated on April 14, 1949 At operation the ulcer appeared to be non malignant, but the patient returned with a recurrence of symptoms in January, 1950, when radiography suggested a neoplasm A further operation, on Feb 1, 1950, revealed an undoubted carcinoma of the pyloric antrum, and a high gastrectomy was done On March 8, 1951, the patient was in excellent health

In his pathological report Dr Skelton says that he thinks it very probable that the tumour (a poorly differentiated adenocarcinoma, penetrating the stomach wall deeply) has arisen in a pre existent chronic peptic ulcer The highest lymph node from the lesser curvature shows no evidence of tumour invasion

Case 3 —A woman, aged 66, who had a perforated gastric ulcer two and a half years ago, has had persistent symptoms for the last twelve months Laparotomy revealed an inoperable carcinoma of the stomach

CONCLUSIONS

Partial gastrectomy has a definite place in the emergency treatment of gastric ulcers in which both hæmorrhage and perforation have taken place

An apparently simple gastric ulcer which has perforated may be malignant

Early gastrectomy should be done if the patient still has symptoms after a perforated gastric ulcer has been sutured

In any case a careful follow up should be made of such cases

I am indebted to Mr J E Andrews, of the Southern Group Laboratory, Hither Green, for the photomicrographs

OUTPATIENT TREATMENT OF THE INJURED HAND

Maurice Ellis
M B Camb, F R C S, D T M & H

From the Casualty Department, General Infirmary at Leeds

The efficient treatment of the lacerated hand, so that the patient returns to work at the earliest date with a soundly healed wound, is of increasing importance Probably the biggest factor retarding healing is sepsis. This inquiry was instituted to find out the incidence of sepsis in lacerated hands treated in the busy casualty department of a general hospital Results of such an inquiry would then serve as a yardstick by which the merits of new methods could be measured Towards the end of the inquiry the Medical Research Council (1949) reported on this subject, dealing largely with the bacteriological aspect of infection Our inquiry dealt purely with the clinical aspect, and this account of methods and results is published as complementary to the M R C report

INFECTION AND SEPSIS

In the control of sepsis in wounds a considerable number of factors must be taken into account, but they may be placed in two large groups The first group of factors are those that have to do with the organisms and their entry into the wound The second group are those that have to do with the patient and his ability to prevent these organisms from gaining a foothold—i e, causing an infected wound The bacteriologist almost wholely concerns himself with the first group

The means whereby the infecting organism can reach the wound are

1. The organism can be carried into the wound at the time of wounding either on the wounding agent or from the surrounding skin
2. From the hands, implements, or covering used at the first aid dressing
3. From the air, the pharynx, or the hands of the surgeon in the operating theatre
4. From the implements or dressings used in the operating theatre
5. From sources 3 and 4 at the times of subsequent dressings and removal of stitches

In theory all these factors except the first should be capable of elimination, but theory and practice often differ widely The M R C report shows how infecting organisms can appear in the wound that were not there at the time of wounding Without doubt, if each minor lacerated wound was treated from its origin, and during its subsequent dressings until it was healed, with full major operating theatre ritual, the low incidence of infection from extraneous sources would please even the bacteriologist But practical realities and even sheer economic necessity preclude our using such a ritual for minor cases At the Birmingham Accident Hospital they deal only with accident cases and their problems are not so complicated as most other hospitals. Like the casualty department in all general hospitals, the casualty department in the General Infirmary in Leeds, is the receiving room for all emergency cases, besides accidents we have to deal with septic hands, abscesses of different kinds, and all other ambulant surgical infections The casualty officer has also to examine and dispose of acute surgical and medical admissions There is constant traffic in and out In Leeds, admittedly one of the busiest casualty departments in the country, there are about 34,000 new cases a year and over 80,000 attendances. The number of operations done in the one casualty theatre is over 600 a month In spite of the fact that dressings are done as infrequently as

SUMMARY

The causes of sepsis in lacerated wounds of the hand are discussed; cross infection is suggested as the chief danger to the wound.

An "assembly line" method of dressing wounds in a busy casualty department is described.

The incidence of sepsis in 555 cases of lacerated hand sutured in the casualty department of the Leeds General Infirmary is shown to vary with the initial amount of laceration or contamination and with the skill of the student dressers.

PULMONARY AND PERIPHERAL CIRCULATION TIMES IN HÆMORRHAGIC SHOCK*

S. R. MUKHERJEE

SENIOR LECTURER IN MEDICAL PHYSICS IN THE UNIVERSITY

In shock a well recognised feature is slowing of the peripheral circulation, but little is known about the extent of this slowing in the capillaries. Accordingly we have measured the time taken by blood to traverse the whole of a peripheral capillary bed.

METHOD

The experiments were made on cats. The circulation time between two points in a circuit was determined by

TABLE I—TIME TAKEN FOR RADIOACTIVE RED CELLS TO CIRCULATE FROM FEMORAL ARTERY TO CAROTID ARTERY WITH BLOOD VOLUME NORMAL

Expt no	Body-weight (kg.)	Blood-pressure (mm. Hg)	Circulation time (sec.)
1	3·0	95	9–11
2	2·5	90	9–10
3	3·0	80	9–10
4	3·4	110	10–11
5	3·0	105	10–11
6	3·4	150	9–11
			(limits 9–11)

injecting radioactive red blood-cells at one point and then taking samples of blood at the *other point*, at known intervals, and examining them for radioactivity. The circulation time was taken to lie between the time of appearance of the first sample which showed radioactivity and the time of its immediate precursor which did not. The positions of the injection and sampling points are shown in figs. 1 and 2. It will be noted that, if these are the femoral artery and the carotid artery, the labelled blood has traversed a peripheral bed and the pulmonary circuit, giving the total circulation time (T.C.T.). If the points are the femoral vein and the carotid artery, only the capillaries of the lung are traversed, giving the lung circulation time (L.C.T.). These times were measured both in normal and in shocked animals. As the results have been consistent, it has been possible to calculate the peripheral circulation time (P.C.T.) as the difference between the T.C.T. and the L.C.T. (figs. 3 and 4)—i.e., T.C.T.—L.C.T. = P.C.T. Owing to the low blood pressure on the venous side, it was impossible to measure the P.C.T. directly by taking samples of blood from a vein at short intervals.

EXPERIMENTAL PROCEDURE

Although other substances have been used to measure circulation time, there is no doubt that radioactive substances give the most reliable values. In our experiments red cells have been labelled with the radioactive

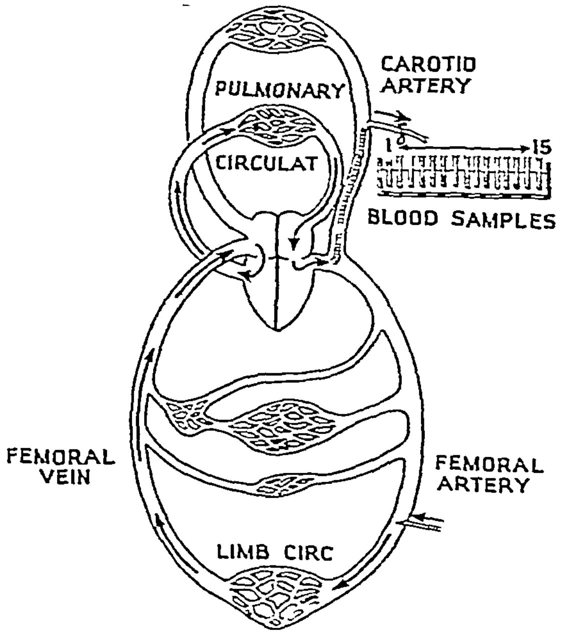

Fig 1—The labelled blood is injected into the femoral artery and traverses the limb (peripheral) capillary bed and the pulmonary capillary bed. The blood samples are collected from the cannula in the carotid artery. The cannula is inserted down to the level of the arch of the aorta. (*Based on Best and Taylor 1944.*)

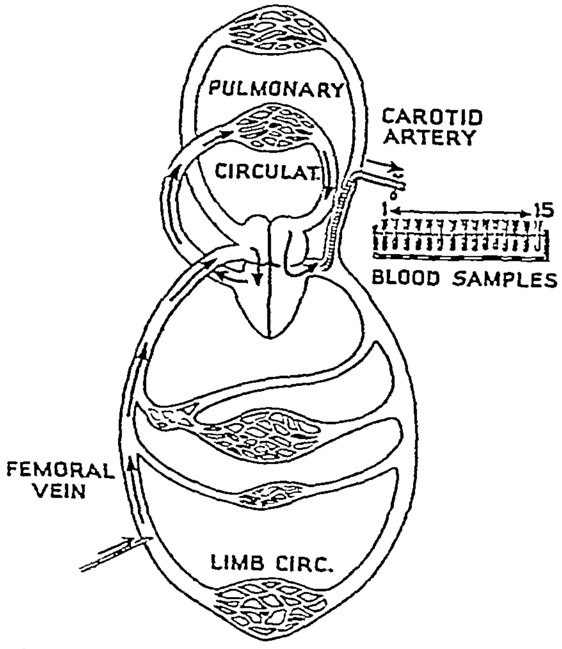

Fig 2—The labelled blood is injected into the femoral vein and traverses only the pulmonary capillary bed before the blood samples are collected.

*Paper presented to the Scottish Society for Experimental Medicine in Dundee on Oct. 14, 1950.

the dresser on the placing of the sutures Penicillin procaine injections were given as required The dressing was left in place for 5 days, and then the wound was inspected In most cases the stitches were now removed, the dressing was reapplied, and the patient was told to attend again for a final inspection on the 10th day At the inspection any clinical signs of sepsis were noted, together with any gaping of the wound margins

It should be realised that in these subsequent dressings of lacerated wounds, septic fingers and other abscesses were inspected and dressed in turn with the lacerations This practice is probably common to very many casualty departments As previously explained, with the volume of work in the casualty department of any busy general hospital, from the practical point of view this is to some extent inevitable

The figures presented here represent consecutive cases as they came to the casualty department over about 6 months There has been no selection of cases, except for two fortuitous short gaps of about a week each, which occurred while we were waiting for a fresh supply of the special chart on which the results were recorded Twenty patients who did not come back for inspection after the wound had been sutured have been excluded

The chart, both sides of which are shown in the figure, was devised to make the recording of pertinent facts as easy and simple as possible The term "hours" represents the time interval between the receipt of the injury and treatment The wounds were divided into lacerations and crushed wounds, in the assessment of the results no significant difference was found in the healing of these, and they have therefore all been classified together The lacerations were graded as follows grade 0 was a wound such as might be produced by a surgical incision, grade 1 represented a wound slightly more ragged than this, and the grading then proceeded with increasing laceration and/or contamination up to grade 4, where this was very severe I had four different junior casualty officers working with me during this inquiry, and after a short time our independent grading of the degree of lacerations usually coincided

At the first inspection of the wound, when the stitches were usually taken out, the amount of pus or sepsis present and any gaping of the skin edges were also graded In those wounds in which gaping was noticed a special search for the clinical signs of sepsis was made at the next inspection of the wound Any case showing sepsis at any time was regarded as a septic wound We tried to be as severe in our criticisms as possible

RESULTS

There were 555 cases in the series In 23 (4 1%) of these the wound was classed as septic The analysis of the wound according to the grading reveals some interesting features

Grade	*No of cases*	*No septic*
0	40	0
1	226	4 (*1 8%*)
2	186	10 (*5 4%*)
3	77	3 (*4 0%*)
4	27	6 (*22 2%*)

At first sight these figures show what might be expected With little or no tissue damage (grade 0 and 1) the incidence of sepsis was very small, with greater laceration (grades 2 and 3) about 5% of wounds turned septic, and with severe laceration (grade 4) about 25% did so

As already mentioned, these wounds were sutured almost entirely by student surgical dressers In the middle of the inquiry the surgical appointments finished for one batch of dressers, and the new batch appeared in casualty to take over their work The first batch of dressers were responsible for 324 cases, and the second batch for 231 cases After the inquiry had been proceeding for several weeks, an interim check on the discharged cases was made to find out the approximate incidence of sepsis 199 cases had been discharged, and of these 13 (6 5%) had shown sepsis These results were communicated to the students, and encouraging talks were given to them to improve on this Of the next 125 cases 2 (1 6%) became septic

When a new batch of students came they had little or no experience of sutures and dressings The methods of suturing were demonstrated to them by myself or my junior casualty officers, and the students were encouraged to practise using needles and forceps to sew cloth or other material at home Of the first 50 cases treated by the new batch of students 6 (12%) became septic Further demonstrations of encouragement were given, and as a result only 2 (1 1%) of the next 185 cases became septic

These figures show quite clearly the results achieved after skill and experience had been acquired by the students and after they had been stimulated to attend to the minor points of detail in cleaning and dressing the wounds The number of students in each batch was over thirty, therefore each student would not have attended very many cases, and even with this small experience an adequate level of competence was soon reached

Effects of Penicillin

After the first batch of students had left, the incidence of sepsis in their cases was checked against the use of penicillin In grade 0 cases penicillin was rarely used, but none of these cases became septic Of 143 cases in group 1 78 had been given 600,000 units of procaine penicillin at the time of suture and the remaining 65 had no penicillin There were 2 septic wounds in the penicillin cases and 2 in the non penicillin cases, and all these 4 cases had occurred in the first 199 cases It was therefore felt that, with careful suturing, penicillin was unnecessary, and it was therefore decided not to use penicillin for grades 0 and 1 until a further review had been made In the next 83 cases in *grade 1* there were no septic wounds In grade 2 cases *600,000* units of procaine penicillin was given at the time of suture and no more until the wound was inspected for the removal of stitches on the 5th day In grades 3 and 4 it was considered that the full use of penicillin should be made, and we aimed to give 600,000 units of procaine penicillin on alternate days until the wound was soundly healed, the patients did not all attend for these injections That this precaution was necessary is shown in two cases in grade 3 The wound had been inspected on the 5th day, when the stitches were removed The wound was inspected again on the 10th day and considered to be soundly healed Penicillin had been given on days 0, 2, 5, and 8 On the 10th day both patients were discharged On the 13th day, however, they returned with lymphangitis spreading up the arms from the wound, which had not broken down The lymphangitis was rapidly cured with penicillin I suggest that in these cases a secondary streptococcal invader had appeared in the wound, and while penicillin was present this streptococcus had not had a chance to multiply When the effect of the penicillin had worn off, the streptococcus multiplied and produced clinical infection These two cases quite clearly bear out the danger of secondary streptococcal invasion of the wound, which the M R C report showed bacteriologically to be quite common

CONCLUSIONS

The rate of sepsis in lacerated wounds of the hand depends on the degree of laceration and/or contamination at the time of wounding, and the degree of skill used in the initial treatment and subsequent dressings of the wound

If a reasonable degree of skill is used at the initial suturing, the method of dressing by the "assembly line" principle is adequate to keep down the infection-rate of the wounds to less than 2%

SUMMARY

The causes of sepsis in lacerated wounds of the hand are discussed, cross infection is suggested as the chief danger to the wound

An "assembly line" method of dressing wounds in a busy casualty department is described

The incidence of sepsis in 555 cases of lacerated hand sutured in the casualty department of the Leeds General Infirmary is shown to vary with the initial amount of laceration or contamination and with the skill of the student dressers

*Paper presented to the Scottish Society for Experimental Medicine in Dundee on Oct 14 1950

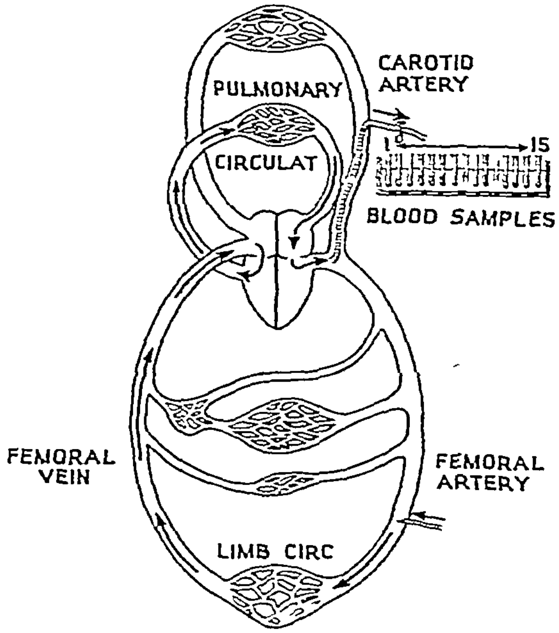

Fig. 1—The labelled blood is injected into the femoral artery and traverses the limb (peripheral) capillary bed and the pulmonary capillary bed. The blood samples are collected from the cannula in the carotid artery The cannula is inserted down to the level of the arch of the aorta. (Based on Best and Taylor 1944.)

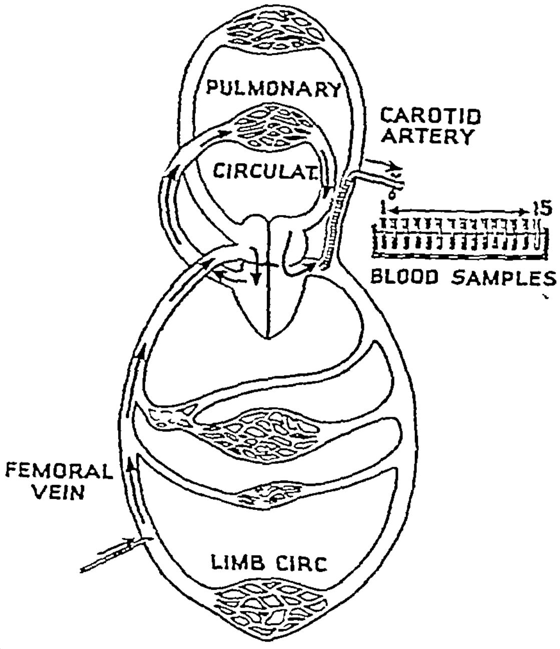

Fig 2—The labelled blood is injected into the femoral vein and traverses only the pulmonary capillary bed before the blood samples are collected.

TABLE II—TIME TAKEN FOR RADIOACTIVE RED CELLS TO CIRCULATE FROM FEMORAL VEIN TO CAROTID ARTERY WITH BLOOD VOLUME NORMAL

Expt no	Body weight (kg)	Blood pressure (mm Hg)	Circulation time (sec)
1	3 0	110	3–4
2	2 5	100	3–4
3	3 0	120	4–5
4	3 5	110	3–5 (limits 3–5)

isotope P^{32} by the method described by Hevesy and Zerahn (1942), which has the advantage that the test substance is whole blood and not some substance foreign to the circulation In addition, the radioactive substance is firmly attached to the red cells, and the quantity lost to the plasma or tissue fluids in the course of an experiment is negligible

The animal is anæsthetised with 'Nembutal' and laid on its back Blood pressure is recorded from the right femoral artery Immediately before an injection is made, the speed of the drum is increased to record in seconds The labelled red cells in whole blood are injected into the left femoral vein or the left femoral artery at a time recorded on the drum with a mechanical time marker For 2 minutes samples are taken at intervals of 1–2 seconds from the left carotid artery into small tubes, the time of each sampling being recorded

To assay the samples, 0 1 ml of blood is withdrawn from each tube and dried in a thin uniform layer on a standard nickel counting planchet The activity of each sample is then estimated with a Geiger Müller counter

It was found unnecessary to make any correction for the fraction of a second taken by the blood to pass through the cannula in the carotid artery

RESULTS

In the first series the blood volume was normal and the circulation time was measured in six cases from the femoral artery to the carotid artery (table I) and in four cases from the femoral vein to the carotid artery (table II)

TABLE III—TIME TAKEN FOR RADIOACTIVE RED CELLS TO CIRCULATE FROM FEMORAL ARTERY TO CAROTID ARTERY WITH BLOOD VOLUME REDUCED

Expt no	Body weight (kg)	Initial blood pressure (mm Hg)	Amount of blood lost (ml per kg)	Final blood pressure (mm Hg)	Duration of hypo tension (min)	Circulation time (sec.)
1	3 0	130	25 0	55	45	22–25
2	5 0	140	22 0	55	45	32–34
3	2 4	100	14 0	65	90	19–21
4	3 2	110	13 5	60	45	23–25
5	4 0	120	20 0	60	120	32–34
6	3 0	130	20 0	40	45	53–55
7	2 2	95	18 0	50	120	36–38
8	3 0	130	27 0	60	60	46–48
9	3 5	140	22 5	80	120	26–29
10	4 2	100	28 0	45	180	55–58 (limits 19–58)

In the second series shock was produced in twenty cases by graded and controlled hæmorrhage In ten cases circulation time was measured from the femoral artery to the carotid artery (table III), and in ten cases from the femoral vein to the carotid artery (table IV)

Tables I and II show that the T C T lies between 9 and 11 seconds and the L C T between 3 and 5 seconds

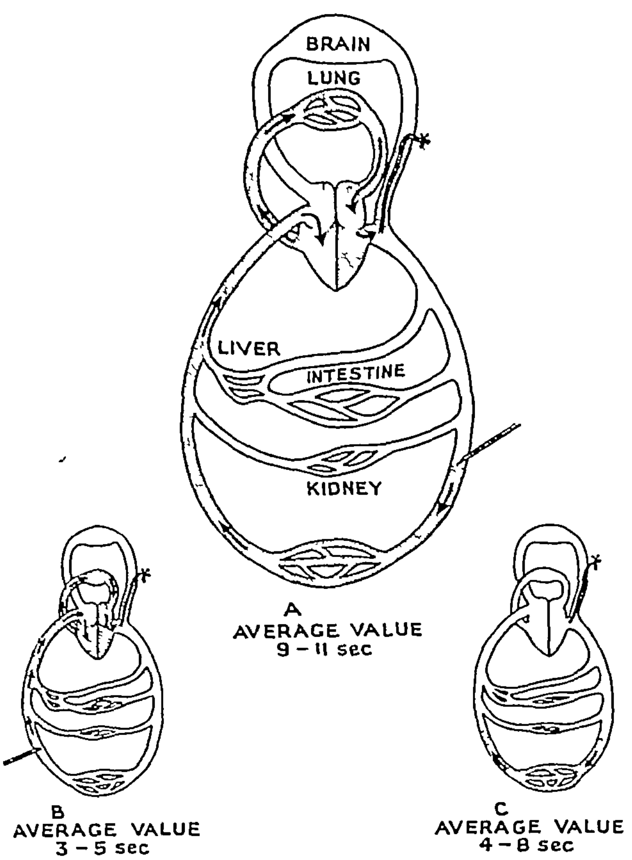

Fig 3—Limits of normal circulation time: A, from femoral artery to carotid artery (see fig 1); B from femoral vein to carotid artery see fig 2) C, peripheral

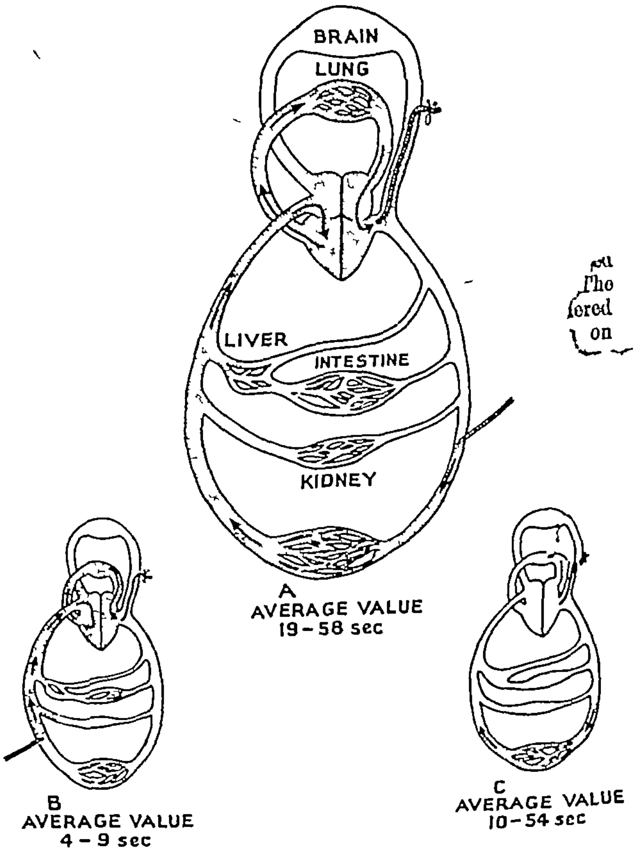

Fig 4—Limits of circulation time in hæmorrhagic shock: A from femoral artery to carotid artery; B from femoral vein to carotid artery; C, peripheral

TABLE IV—TIME TAKEN FOR RADIOACTIVE RED CELLS TO CIRCULATE FROM FEMORAL VEIN TO CAROTID ARTERY WITH BLOOD VOLUME REDUCED

Expt. no	Body weight (kg)	Initial blood pressure (mm. Hg)	Amount of blood lost (ml per kg)	Final blood pressure (mm. Hg)	Duration of hypotension (min)	Circulation time (sec.)
1	2 6	95	30	60	45	4–5
2	2 8	120	21	40	60	4–5
3	3 2	125	21	60	60	4–5
4	3 0	120	20	70	50	4–5
5	3 0	115	25	50	90	5–6
6	3 5	120	25	45	120	7–8
7	2 4	150	36	45	60	7–8
8	3 2	85	17	45	90	6–7
9	3 4	140	27	70	150	8–9
10	4 3	150	36	50	120	8–9 (limits 4–9)

P C T lies therefore between 4 and 8 seconds (fig 3) The data obtained are not yet sufficient for statistical analysis, but these limits serve the present argument well enough

The figures in tables III and IV suggest that the circulation time is definitely increased in hæmorrhagic shock, the L C T has limits of 4–9 seconds but the T C T varies between 19 and 58 seconds These results are plotted in fig 5, which shows that the T C T tends to increase with falling blood pressure, whereas the L C T is little changed Thus it is possible to set a range for the peripheral circulation times after hæmorrhage by subtracting from the limits of the total circulation time the limits for the lung circulation time In this way the P C T after hæmorrhage is seen to lie in the range 10–54 seconds (fig 4) When more data have been collected, it may be possible to express circulation time quantitatively in terms of blood lost per kg of body-weight Even with the present data, if the figures for the oligæmic animals are compared with the figures for those with a normal blood volume, a striking difference is apparent between the pulmonary and peripheral circuits (table V)

TABLE V—PULMONARY AND PERIPHERAL CIRCULATION TIMES WITH NORMAL AND REDUCED BLOOD VOLUMES

Group of animals	Pulmonary circulation time limits (sec.)	Peripheral circulation time limits (sec)
Normal animals	3–5	4–8
Animals in hæmorrhagic hypotension	4–9	10–54

reas in shocked animals the lung circulation time is er doubled, the peripheral circulation time may increase more than six times, a discrepancy which seems to have escaped notice In previous measurements of circulation time, the test substance injected intravenously has been detected in the lung, in the carotid sinus, or in the peripheral vessels before it has traversed the whole of the peripheral capillary bed. Such methods cannot detect the greatly increased peripheral circulation time in hypotension The relatively small effect on lung circulation time of hæmorrhagic hypotension is confirmed by the results of Wang et al. (1947) Using sodium cyanide as the test substance, they measured lung circulation time in dogs in hæmorrhagic hypotension, and observed only a slightly increased time after a hæmorrhage severe enough to be fatal. It is clear that in hæmorrhagic shock the lung circulation is not subject to the same changes as is the peripheral circulation

The relationship between circulation time and percentage reduction in blood pressure is shown in fig 5, which distinguishes between points relating to long and short periods of hypotension It will be noted that in four out of five cases of hæmorrhagic hypotension of short duration the lung circulation times lie within normal limits With prolonged hypotension they show an increase which is small compared with the increase in peripheral circulation time Further experiments will be necessary before it is certain that the duration or severity of hæmorrhagic shock has a significant effect on lung circulation time

When the other points on the graph are examined, it is evident that there is a correlation between percentage fall in blood-pressure and peripheral circulation time, and that the peripheral circulation time increases with the duration of hypotension, because the points relating to prolonged hypotension lie above those relating to short hypotension Further experiments have been planned to investigate the relationships between degree and duration of hæmorrhagic hypotension and peripheral circulation time

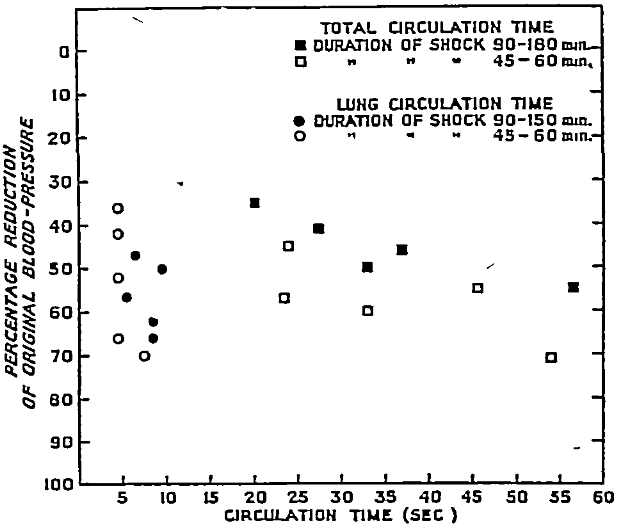

Fig 5—Effect of hæmorrhagic hypotension of long or short duration on lung circulation times (circles) and on peripheral circulation time (squares)

SUMMARY

The blood circulation times have been measured in cats by using red blood cells labelled with a radioactive isotope

In hæmorrhagic hypotension the peripheral circulation time increases considerably with fall in blood-pressure, whereas the increase in the lung circulation time is relatively small.

Peripheral circulation time is increased by prolonging the state of hypotension

One of us (S R M.) was assisted by a Government of India scholarship

The medical planners express deep concern that the general practitioner should be tempted to tackle work outside his competence,' a loose phrase typical of many in common use today In this connection it can at once be pointed out that errors of judgment and technique cling to a general practitioner, who lives amongst his patients far more tenaciously than to a consultant protected as he is by his status and grading the fear of bad results makes it extremely unattractive for the general practitioner to attempt things outside and, often enough well within his competence I wonder if the specialist is not more likely to attempt things outside his competence than the general practitioner is to attempt things outside his '—C J L WELLS, *Postgrad med J* 1951 27, 237

TABLE II—TIME TAKEN FOR RADIOACTIVE RED CELLS TO CIRCULATE FROM FEMORAL VEIN TO CAROTID ARTERY WITH BLOOD VOLUME NORMAL

Expt no	Body weight (kg)	Blood pressure (mm Hg)	Circulation time (sec)
1	3 0	110	3–4
2	2 5	100	3–4
3	3 0	120	4–5
4	3 5	110	3–5 (limits 3–5)

isotope P³² by the method described by Hevesy and Zerahn (1942), which has the advantage that the test substance is whole blood and not some substance foreign to the circulation In addition, the radioactive substance is firmly attached to the red cells, and the quantity lost to the plasma or tissue fluids in the course of an experiment is negligible

The animal is anæsthetised with 'Nembutal' and laid on its back Blood pressure is recorded from the right femoral artery Immediately before an injection is made, the speed of the drum is increased to record in seconds The labelled red cells in whole blood are injected into the left femoral vein or the left femoral artery at a time recorded on the drum with a mechanical time marker For 2 minutes samples are taken at intervals of 1–2 seconds from the left carotid artery into small tubes, the time of each sampling being recorded

To assay the samples, 0 1 ml of blood is withdrawn from each tube and dried in a thin uniform layer on a standard nickel counting planchet The activity of each sample is then estimated with a Geiger Müller counter

It was found unnecessary to make any correction for the fraction of a second taken by the blood to pass through the cannula in the carotid artery

RESULTS

In the first series the blood volume was normal and the circulation time was measured in six cases from the femoral artery to the carotid artery (table I) and in four cases from the femoral vein to the carotid artery (table II)

TABLE III—TIME TAKEN FOR RADIOACTIVE RED CELLS TO CIRCULATE FROM FEMORAL ARTERY TO CAROTID ARTERY WITH BLOOD VOLUME REDUCED

Expt no	Body weight (kg)	Initial blood-pressure (mm Hg)	Amount of blood lost (ml per kg)	Final blood pressure (mm Hg)	Duration of hypo tension (min)	Circulation time (sec.)
1	3 0	130	25 0	55	45	22–25
2	5 0	140	22 0	55	45	32–34
3	2 4	100	14 0	65	90	19–21
4	3 2	110	13 5	60	45	23–25
5	4 0	120	20 0	60	120	32–34
6	3 0	130	20 0	40	45	53–55
7	2 2	95	18 0	50	120	36–38
8	3 0	130	27 0	60	60	45–46
9	3 5	140	22 5	80	120	26–29
10	4 2	100	28 0	45	180	55–58 (limits 19–58)

In the second series shock was produced in twenty cases by graded and controlled hæmorrhage In ten cases circulation time was measured from the femoral artery to the carotid artery (table III), and in ten cases from the femoral vein to the carotid artery (table IV)

Tables I and II show that the T C T lies between 9 and 11 seconds and the L C T between 3 and 5 seconds

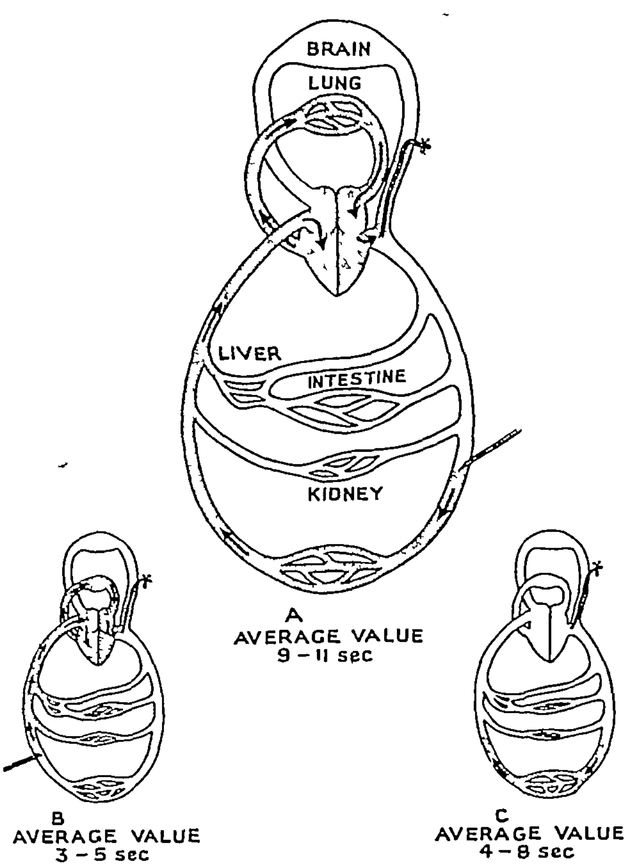

Fig. 3—Limits of normal circulation time: A from femoral artery to carotid artery (see fig 1); B from femoral vein to carotid artery see fig 2) C peripheral

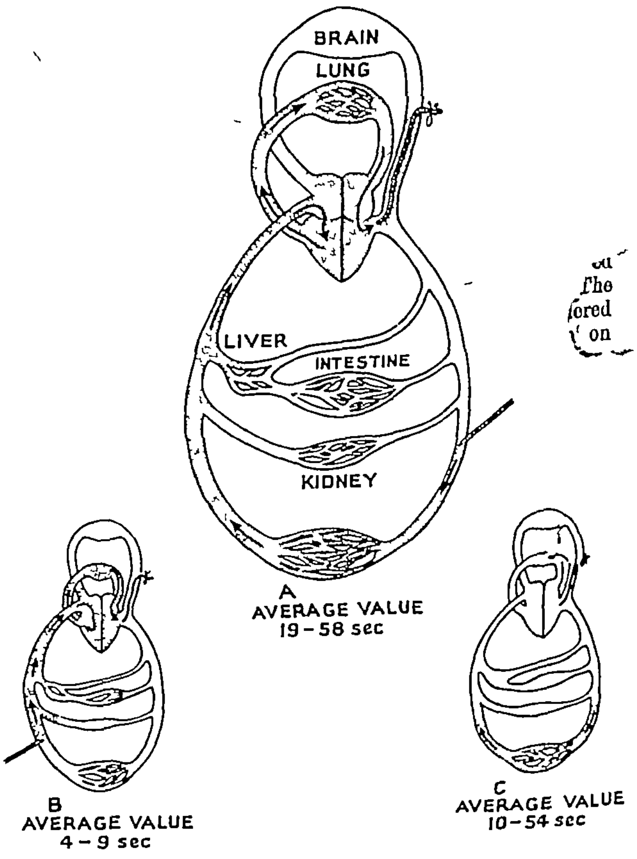

Fig 4—Limits of circulation time in hæmorrhagic shock: A, from femoral artery to carotid artery; B from femoral vein to carotid artery C peripheral

in the tube and saturated with carbon monoxide or coal gas. Water is added to the 100% mark and gently shaken. The ratio of the photo-electric readings (test standard) is multiplied by 100 and by the N.P.L. factor to give the concentration of hæmoglobin in percentage of Haldane normal, or by 14·8 × the factor to give g. of Hb per 100 ml. of blood.

INSTRUMENTS

Visual Photometer.—This was the Medical Research Council grey wedge photometer described by King (1947) and King et al. (1948c). It was made by Keeler Optical Products and fitted with an Ilford 625 bright spectrum yellow-green filter.

Spectrophotometer.—This was a Beckman DW instrument with which 1 cm. cells were used. Measurements were made at 540 mμ, and the density scale was checked with a calibrated grey screen.

Photo-electric Photometers.—A Spekker absorptiometer manufactured by Hilger & Watts was equipped with 1 cm. cells and Ilford 625 filters. The same filter was also used in a single-cell test-tube colorimeter made by EEL. Measurements were made with the normal cuvette (equivalent light-path about 1·3 cm.) on all solutions except carboxyhæmoglobin. The last-named was used as described above.

Conversion Factors.—The experimental results were converted into hæmoglobin content (g. per 100 ml.) by the following means:

(1) the Hüfner factors were used for the iron and gas analyses—i.e., Hb contains 0·334% Fe; 1 g. Hb ≡ 1·34 ml. O_2 or CO;

(2) the readings at 540 mμ on the Beckman instrument were divided by the specific extinctions given by Donaldson et al. (1951) and the calculated extinction coefficients given in that paper (for coloured solutions from 100% bloods, as measured through the 625 filter) were used to convert the Spekker values to g. of Hb per 100 ml.;

(3) the M.R.C. photometer and the carboxyhæmoglobin method with Haldane tubes provided results on the Haldane scale (the equivalent 100% ≡ 14·8 g. of Hb per 100 ml. was used); and

(4) the EEL photo-electric instrument with the normal size cuvette had previously been calibrated with a series of normal blood samples of known iron content.

RESULTS

The results are given in the accompanying table. In each group the mean value of the hæmoglobin content found by each method has been calculated. The figures in parentheses are the coefficients of variation of each result from the iron analysis of the corresponding blood sample.

DISCUSSION

The base-line results (iron and gas capacity) show a pattern already familiar from the earlier papers in this series dealing with normal blood samples. Iron analysis and total hæmoglobin measured by CO capacity after reduction are in good agreement. The oxygen capacity is about 3–5% lower, presumably because it does not measure inactive hæmoglobin (and methæmoglobin if present). In the present samples these inactive pigments seem to be present in normal amounts.

In the colorimetric methods there is also good agreement between the average hæmoglobin values and the iron results. Many of the coefficients of variation are higher than those found using similar methods on normal blood samples. However, the average hæmoglobin concentrations of this present series are much lower than those found previously. The coefficient of variation is calculated by expressing the standard deviation as a percentage of the mean; hence the diminished mean values have correspondingly increased the coefficient of variation.

The calculation of the results has involved the use of factors, extinction coefficients, &c., which had been determined in experiments with normal blood. It is apparent that these coefficients are appropriate to the pathological blood samples studied here. The earlier papers in this series presented conclusions drawn from hæmoglobin methods applied to samples of blood from healthy laboratory personnel and other normal people. These conclusions seem applicable also to the estimation of hæmoglobin in pathological blood samples.

SUMMARY

The hæmoglobin content of 56 blood samples has been estimated. Most of the blood samples were drawn from patients with diseases affecting the blood.

Agreement was good between the results obtained by accurate analytical methods and the results obtained by colorimetry.

The extinction coefficients, &c., calculated on normal blood can be used in work on samples of pathological blood.

The average hæmoglobin values, as determined with instruments calibrated purely from an optical-density basis, are in as good agreement with the value derived from iron as are the results from an instrument calibrated by means of material standards.

This investigation has been made for the Medical Research Council's subcommittee on analytical methods. The expenses were partially defrayed by a grant from the Medical Research Council, to whom grateful acknowledgment is made. Our thanks are due to Sir Charles Harington, chairman of the subcommittee, for much valuable advice.

CORONARY OCCLUSION IN YOUNG ADULTS

REVIEW OF A HUNDRED CASES IN THE SERVICES

MAURICE NEWMAN
M.D. Lpool, M.R.C.P.
PRINCIPAL MEDICAL OFFICER, MINISTRY OF PENSIONS

In a previous paper (Newman 1946) I collected and analysed the Service records of 50 cases of coronary occlusion in Service personnel aged up to 35. The analysis showed that severe degenerative changes can exist in the coronary arteries at an early age, and that coronary disease is not so rare in the young as was formerly thought.

I report here a further 50 similar cases in men and women since discharged or released from the Services, and review the whole series of 100 cases. As before, only those cases have been selected where the diagnosis was beyond doubt—i.e., either proved by necropsy or where the electrocardiogram supported the clinical diagnosis. All doubtful cases have been excluded. Of the 50 cases in the present series the diagnosis was established clinically in 9 and at necropsy in 41.

AGE INCIDENCE

The youngest patient in this series was aged 21, and 11 of the 50 patients were in their twenties. As in the previous series the frequency of coronary occlusion

DETERMINATION OF HÆMOGLOBIN

VIII ACCURACY OF METHODS APPLIED TO ABNORMAL BLOODS

E J King R J Bartholomew M Geiser
S Ventura I D P Wootton
Postgraduate Medical School of London
R G Macfarlane
Radcliffe Infirmary, Oxford
R Donaldson R B Sisson
National Physical Laboratory, Teddington

The determination of hæmoglobin has been studied, and described in previous papers of this series, with clinical instruments (Macfarlane et al. 1948), by iron analyses, oxygen and carbon monoxide capacities (King et al 1948a), by several colorimetric and photometric procedures (King et al 1948b), and with a simple grey-wedge instrument, the M R C photometer (King et al 1948c), and the photometric measurement of the various coloured derivatives of hæmoglobin by visual and photo electric means was critically reviewed by Donaldson et al. (1951)

The net conclusion of these investigations has been that it is possible to determine hæmoglobin with a high degree of accuracy by analysis of blood for a constituent of the hæmoglobin molecule (i e, iron), by measurement of a chemical reaction in which hæmoglobin takes part (i e, carbon monoxide combining capacity after reduction, but not so accurately by oxygen capacity), and by accurate photometry of the concentration of coloured derivatives of hæmoglobin—oxyhæmoglobin, carboxyhæmoglobin, cyanmethæmoglobin, acid and alkaline hæmatin, and cyanhæmatin—provided that the chemical reaction takes place under suitable conditions and is given sufficient time to go to completion (e g, with acid hæmatin) All the coloured derivatives studied yielded satisfactory results when their light absorptions were accurately assessed, but it was concluded that, for simplicity of preparation and closeness of agreement with base line measurements of iron and carbon monoxide capacities, the oxyhæmoglobin and the cyanhæmatin procedures were to be favoured, the former for visual assessment and the latter for photo electric

All these previous studies have been concerned with the investigation of samples of blood procured from normal healthy people It has remained to test the methods, and the conclusions reached, on blood samples taken from persons with the more important diseases in which the blood pigment may be abnormal The present paper describes this work

METHODS

Blood Samples—25 ml specimens were taken from an antecubital vein and transferred to bottles containing the residue from four drops of 30% potassium oxalate In most cases the analyses were made on the same day Iron titrations and, occasionally, other manipulations were completed next day The samples were all obtained from patients in Hammersmith Hospital They have been placed in five groups (see table) Group A were normal bloods—i e, from patients with conditions not affecting the blood—and B and C were from patients with various forms of anæmia The specimens in group D were from jaundiced patients, and group E contained miscellaneous conditions, including six cases of methæmoglobinæmia

Iron analyses were made by titanous chloride titrations of ashed samples with the all glass microburette modified by Wootton and King (1948) from Trevan (1925) The method is described in full by King et al (1948a) and King (1951)

Gasometric Estimations—With the manometric Van Slyke apparatus, oxygen capacity was estimated by the method of Van Slyke and Neill (1924) The carbon monoxide method after reduction with hydrosulphite was done by the recent modification described by Van Slyke et al (1949)

Hæmoglobin Derivatives—The methods for making the coloured solutions have been described by Macfarlane et al (1948) Two modifications must be given in detail

Cyanhæmatin—For making the cyanhæmatin solutions 0 5 ml of blood was added to 49 ml of water in a 100 ml volumetric flask, followed by 0 5 ml of 10 *N*HCl The mixture was allowed to stand for 10 min Sodium phosphate solution (40 ml of 10% Na_3PO_4 $12H_2O$) was added to buffer the solution at an alkaline pH, and then 10 ml of 10% NaCN and water to the mark.

Carboxyhæmoglobin—The Haldane method was used with photo electric colorimeters (EEL, Gallenkamp, Hilger) fitted with micro adapters for the Haldane tubes The Haldane standard, and tube marked only at the 2 ml mark (i e, 100%) (Messrs Hawksley & Son) were given a factor, which takes into account the capacity and the diameter of the tube, for conversion to true hæmoglobin percentages of the readings of test and standard (National Physical Laboratory) Blood (0·02 ml) is washed into about 1 ml of ammonia water 0 4%

COMPARISON OF HÆMOGLOBIN METHODS, WITH COEFFICIENTS OF VARIATION FROM IRON ANALYSES AVERAGES FOR GROUPS OF HOSPITAL PATIENTS, RESULTS IN G OF HÆMOGLOBIN PER 100 ML OF BLOOD, WITH COEFFICIENTS OF VARIATION AS PERCENTAGES IN PARENTHESES

with lesions of the conducting bundles. There was no evidence of rheumatic disease. The coronary arteries showed very advanced atheroma, which (the pathologist said) "at his age can only be described as precocious in the extreme." There was also shortening or deficiency in the cusps of the valves, not inflammatory.

The association of congenital morbus cordis with advanced atheroma of the coronary arteries in this case implies a congenital weakness of the coronary arterial system, and supports the contention that genetic influences play a more important part than extraneous factors in coronary disease in young adults.

All the 9 patients in the second series who have survived the initial attack of coronary occlusion are still alive 3–6 years after the occlusion. They are all working in similar occupations to their pre-Service ones, but symptoms such as shortness of breath on effort, pain, and tightness in the chest on exertion are complained of by all.

NECROPSY FINDINGS

The necropsy findings in the present series of 41 deaths were similar to those in the previously published cases. The left coronary arteries were much more frequently affected than the right—13 left and 3 right. Both coronary arteries were affected in 20 cases. In the remaining it was not stated which coronary arteries were affected. In 18 of the 41 cases the heart was enlarged, and in 1 patient, aged 32, the heart was very large, owing to aneurysmal dilatation of the left ventricular wall. The heart muscle was very thin and there was much fibrous tissue. Both coronary arteries showed considerable atheroma, and the first half-inch of the descending branch of the left coronary artery was completely occluded by atheroma. This man had died suddenly, four months after release while working as a stone finisher. He had to lift heavy weights. A thrombus was found in only 12 cases. In 8 cases myocardial infarction was found either recent or old standing.

In the total series of 80 deaths, the left coronary artery was affected in 30 cases, the right in 8 cases, and both were involved in 36 cases. The heart was enlarged in 38 cases—i.e., in about half. Myocardial infarction, either recent or old, was found in 25 cases. A thrombus was found in only 22 of the 80 cases. The degenerative changes found in the coronary vessels were similar to those found in the older age groups, the arteries being thickened, tortuous, and calcified. Occlusion took place in the non-thrombus cases as the result of the gross atheroma or of an atheromatous plaque blocking the lumen. Atheroma of the aorta was also present in most cases.

These findings do not support Leary's (1941) view that in the younger age group the pathological changes differ from those in the older age group (over 45), thrombosis being more common, and calcification not occurring, in the younger group.

DISCUSSION

This further series of 50 cases of coronary occlusion in young people confirms my previous view that advanced degenerative changes in the coronary arteries may exist at an early age, and that coronary occlusion is not so rare as was formerly thought. It is remarkable that, in spite of the advanced degenerative changes present in their coronary arteries, these patients appear to be in excellent health and can serve as grade I men for several years, many overseas in combatant units, without any symptoms or signs of cardiac inadequacy until occlusion takes place. Full clinical examination, even a few hours before the occlusion, as happened in 2 cases, revealed no indication of the underlying degenerative arterial disease with its impending crisis. In only 1 case was the coronary occlusion preceded by angina pectoris, which in view of the youth of the patient and normal radiogram and electrocardiogram was not diagnosed as true angina but as an irritable heart with no organic lesion.

Coronary disease in young people seems to be predominantly confined to males, only 1 female occurring in the 100 cases. Body-build is an interesting factor because most of the patients were above the average weight for age and height, and such terms as "powerfully built," "well developed," and "muscular" were often used in the necropsy reports.

The second 50 cases do not confirm that infection is an important ætiological factor in coronary disease in young adults, for there was no such history in any. No cases of syphilis occurred in this series, although 2 cases occurred in the previous published series, which confirms that syphilis is a very infrequent cause of coronary disease, as in the older age groups. Hypertension is recorded in 5 out of the 9 surviving cases of the second series. In the previous series it was noted in 3 cases. In view of the fact that in most of the fatal cases the patients had had no illness necessitating investigations during life, the blood pressure was only occasionally recorded in these cases, as on routine examination, and so it is impossible to give the true incidence of hypertension, or discuss its influence as a factor in the ætiology of coronary disease in the young.

Most of these cases of coronary disease in the young fall in the Registrar-General's social classes IV or V, and there seems to be little evidence of any relationship to heavy responsibilities or mental stress. Ryle and Russell (1949), on the other hand, in a study of the epidemiology of coronary disease in the older age groups, found that the incidence of coronary disease was much greater in the business and professional classes, and suggested this was related to mental rather than physical stress. In discussing my first 50 cases these workers state: "Where extraneous factors in early life are far to seek it may possibly be shown that genetic influences play a more important part than habits of life and work."

The high mortality, 80%, is a striking feature in coronary disease in the young. So is the rapid onset of death: sudden death occurred in 74 out of the 80 fatal cases.

The necropsy findings are similar to those found in the older age groups, the coronary arteries showing all stages of atheroma, including calcification and occlusion by atheromatous plaques, with or without thrombus formation, and indicating that, in spite of the youth of the victims, the pathological process has been present for years.

These pathological findings at such an early age, the predominance in males, the body build, and the lack of relationship to mental stress or other extraneous factors support the view that genetic influences are the most important factors in the ætiology of coronary disease in young people.

SUMMARY

100 cases of coronary occlusion in young adults in the Services or following release therefrom are reviewed.

All the patients but one were males, and of good physical development and previous good health.

Infection rarely seems to be an ætiological factor.

The great majority of cases fall in the Registrar-General's social classes IV or V, and there is little evidence of any relationship to heavy responsibilities or mental stress. Physical stress occurred in less than half the cases.

The mortality was 80%, with sudden death in 74 of the 80 fatal cases.

At necropsy the atheromatous changes in the coronary arteries were similar to those usually described in the older age groups. A thrombus was found in only 22 of the 80 fatal cases.

TABLE I—AGE INCIDENCE

Age (yr)	20	21	22	23	24	25	26	27	28	29	30	31	32	33	34	35
No of cases	1	3	4	3	3	3	1	4	9	2	9	8	10	11	12	17
No in 4 yr and 8 yr groups	11				11				28				50			
	22								78							

increased with age, as in the older age groups The age incidence of the combined series is shown in table I It will be noted that half the cases occurred in persons aged less than 32, and that 33 cases were in persons aged less than 30, the youngest being aged 20

SEX-INCIDENCE

In the first 50 cases there was only 1 female, and in the present series there were no females, hence the incidence of female cases was only 1 in 100 Even allowing for the greater number of males to females in the Services —10–15 males to 1 female—there seems no doubt that coronary disease in the young is very rare in females

BODY BUILD

In the earlier report I remarked on the good physical development and nourishment of these young adults, 43 of the patients weighing more than 126 lb on entry into service, and many more than 150 lb In the second 50 only 8 weighed less than 126 lb on entry into service, 28 weighed more than 140 lb, and 16 more than 150 lb The highest weight was 202 lb on entry which increased to 240 lb at the time of the occlusion Physical fitness was again shown by the fact that 46 of the second 50 were graded A1 or fit on entry, and of the 4 exceptions 3 were downgraded for minor defects (flat foot and poor vision), the heart and general development being recorded as normal In the remaining case the man was graded II owing to enlargement of the heart shown on radiological examination He was accepted for service because there were no symptoms Subsequent necropsy showed he had congenital morbus cordis Since 45 of the first 50 were graded fit, or I, on entry, 91 of the 100 were graded fit, or I, on entry

PREVIOUS INFECTION

In the first 50 cases 3 patients gave a history of rheumatic fever and 2 of scarlet fever before entry into service In the second 50 none gave such a history Hence it seems that previous infection is rarely, if at all, a causal factor of coronary disease in young people

PRE SERVICE OCCUPATION

Of 49 recorded occupations in the second 50 cases only 6 were sedentary Of the 43 non sedentary occupations 25 would be considered as heavy work, 16 patients being labourers Of the 46 recorded occupations in the first 50 cases 8 were sedentary and 23 were heavy work Hence in the total series of 100 cases 14 patients had sedentary occupations before joining up, and 48 did heavy work, 33 being labourers Only 9 out of the 100 patients were officers, and all of these, apart from a doctor and an instructor lieutenant in the Royal Navy, had begun their service as rankers None of the commissioned officers were of higher rank than lieutenant, and they would not have been subject to sustained mental stress with heavy responsibilities Most of the cases of coronary occlusion in young people therefore fall in the Registrar General's social classes IV and V

PHYSICAL STRESS

Half of the second 50 patients had their coronary occlusion after release from service and therefore cannot be directly associated with Service stress The intervals between release from service and the onset of coronary occlusion, together with the post Service occupation, are shown in table II

It will be observed that the interval following release from service varied from 10 days up to 6 years As regards occupations at the time of the occlusion, 3 patients had not yet begun work, and, although 2 were students, none of the occupations could be said to involve mental stress asssociated with responsibility

Of the other 25 patients who had the coronary occlusion during Service, 24 had served more than three years, and 16 more than five years, before the occlusion, and 22 had served in the Middle East The 1 patient who had not served three years had his coronary occlusion three weeks after entry into service, while training In only 9 of these 25 cases did the occlusion come on while the patients were performing duties involving physical stress

TABLE II—ONSET OF CORONARY OCCLUSION IN RELATION TO RELEASE FROM SERVICE AND TO OCCUPATION *

Case no	Interval after service	Post Service occupation	Case no	Interval after service	Post Service occupation
51	1 yr 6 mos	Clerk	79	2 yr 9 mos	Motor mechanic

77	3 yr 6 mos	Clerk	95	2 yr 6 mos	Postman
78	20 days	No work	100	3 yr 9 mos	Law student

PROGNOSIS

In my previous report I remarked on the high mortality (30 deaths) and of the tendency to die quickly after a coronary occlusion (33 patients were found dead, or died almost immediately after a collapse) The second 50 cases show a similar high mortality—41 deaths, making the mortality 80 in the 100 cases

In all 41 fatal cases in the second 50 death took place suddenly and, with 2 exceptions, in apparently fit and healthy men In one case the man, a motor driver since release from service, called at a hospital because of sudden pain in his chest and vomiting The hospital case sheets record "Despite a thorough physical examination nothing abnormal was detected, and he was sent home" He collapsed on the way home and dropped dead

In the 2 exceptions, one complained of angina pain following release from service, but, since the radiogram and the electrocardiogram were normal, he was diagnosed as having an irritable heart with no organic lesion He died suddenly three years later, and necropsy showed complete occlusion of the left coronary artery, with atheromatous plaques

In the other case, a bank clerk, aged 18, was graded II on entry into service, owing to clinical enlargement of the heart, confirmed by radiography, which showed a globular heart consistent with right sided preponderance

> There was no history of rheumatism, he had no symptoms, and the exercise tolerance test was good After three years' uneventful service in this country as an equipment assistant, he was investigated in hospital owing to concussion following a lorry accident The electrocardiogram showed a left bundle-branch block, and the man was invalided with this disability A Kahn test was negative After discharge the patient continued his pre Service occupation as a clerk for three and a half years without any discomfort or need for medical attention, when he suddenly collapsed and died at the age of 25, while out walking with his wife Necropsy disclosed a large heart, wholly diseased with severe fibrosis of the type associated

with absence of the [illegible] cordis. There was no evidence of rheumatic disease. The coronary arteries showed very advanced atheroma, which (the pathologist said) "at his age can only be described as precocious in the extreme." There was also narrowing or calcification in the cusps of the valves but no inflammatory change.

The association of congenital morbus cordis with advanced atheroma of the coronary arteries in this case implies a congenital weakness of the coronary arterial system, and supports the contention that genetic influences play a more important part than extraneous factors in coronary disease in young adults.

All the 9 patients in the second series who have survived the initial attack of coronary occlusion are still alive 3–5 years after the occlusion. They are all working in similar occupations to their pre-Service ones; but symptoms such as shortness of breath on effort, pain, and tightness in the chest on exertion are complained of by all.

NECROPSY FINDINGS

The necropsy findings in the present series of 41 deaths were similar to those in the previously published cases. The left coronary arteries were much more frequently affected than the right—13 left and 3 right. Both coronary arteries were affected in 20 cases. In the remaining it was not stated which coronary arteries were affected. In 18 of the 41 cases the heart was enlarged, and in 1 patient, aged 32, the heart was very large, owing to aneurysmal dilatation of the left ventricular wall. The heart muscle was very thin and there was much fibrous tissue. Both coronary arteries showed considerable atheroma, and the first half-inch of the descending branch of the left coronary artery was completely occluded by atheroma. This man had died suddenly, four months after release, while working as a steel-finisher. He had to lift heavy weights. A thrombus was found in only 12 cases. In 8 cases myocardial infarction was found, either recent or old-standing.

In the total series of 80 deaths, the left coronary artery was affected in 30 cases, the right in 8 cases, and both were involved in 36 cases. The heart was enlarged in 35 cases—i.e., in about half. Myocardial infarction, either recent or old, was found in 25 cases. A thrombus was found in only 22 of the 80 cases. The degenerative changes found in the coronary vessels were similar to those found in the older age-groups, the arteries being thickened, tortuous, and calcified. Occlusion took place in the non-thrombotic cases as the result of the gross atheroma or of an atheromatous plaque blocking the lumen. Atheroma of the aorta was also present in most cases.

These findings do not support Leary's (1934) view that in the younger age-group the pathological changes differ from those in the older age-group (over 45), thrombosis being more common, and calcification not occurring in the younger group.

DISCUSSION

This further series of 50 cases of coronary occlusion in young people confirms my previous view that advanced degenerative changes in the coronary arteries may exist at an early age, and that coronary occlusion is not so rare as was formerly thought. It is remarkable that, in spite of the advanced degenerative changes present in their coronary arteries, these patients appear to be in excellent health and can serve as grade-I men for several years, many overseas in combatant units, without any symptoms or signs of cardiac inadequacy until occlusion takes place. Full clinical examination, even a few hours before the occlusion, as happened in 2 cases, revealed no indication of the underlying degenerative arterial disease with its impending crisis. In only 1 case was the coronary occlusion preceded by angina pectoris, which in view of the youth of the patient and normal radiogram and electrocardiogram was not diagnosed as true angina but as an irritable heart with no organic lesion.

Coronary disease in young people seems to be predominantly confined to males, only 1 female occurring in the 100 cases. Build is an interesting factor because most of the patients were above the average weight for age and height, and such terms as "powerfully built," "well developed," and "muscular" were often used in the necropsy reports.

The second 50 cases do not confirm that infection is an important aetiological factor in coronary disease in young adults, for there was no such history in any. No cases of syphilis occurred in this series, although 2 cases occurred in the previous published series, which confirms that syphilis is a very infrequent cause of coronary disease, as in the older age-groups. Hypertension is recorded in 5 out of the 9 surviving cases of the second series. In the previous series it was noted in 3 cases. In view of the fact that in most of the fatal cases the patients had had no illness necessitating investigation during life, the blood-pressure was only occasionally recorded in these cases, as on routine examination, and so it is impossible to give the true incidence of hypertension, or discuss its influence as a factor in the aetiology of coronary disease in the young.

Most of these cases of coronary disease in the young fall in the Registrar-General's social classes IV or V, and there seems to be little evidence of any relationship to heavy responsibilities or mental stress. Ryle and Russell (1949), on the other hand, in a study of the epidemiology of coronary disease in the older age-groups, found that the incidence of coronary disease was much greater in the business and professional classes, and suggested this was related to mental rather than physical stress. In discussing my first 50 cases these writers state: "Where extraneous factors in early life are far to seek it may possibly be shown that genetic influences play a more important part than habits of life and work."

The high mortality, 80%, is a striking feature in coronary disease in the young. So is the rapid onset of death: sudden death occurred in 74% of the 80 fatal cases.

The necropsy findings are similar to those found in the older age-groups, the coronary arteries showing all stages of atheroma, including calcification and occlusion by atheromatous plaques, with or without thrombus formation, and indicating that, in spite of the youth of the patients, the pathological process has been present for years.

These pathological findings at such an early age, the predominance in males, the build, and the lack of relationship to mental stress or other extraneous factors support the view that genetic influences are the most important factors in the aetiology of coronary disease in young people.

SUMMARY

100 cases of coronary occlusion in young adults in the Services or following release therefrom are reviewed.

All the patients but one were males, and of good physical development and previous good health.

Infection rarely seems to be an aetiological factor.

The great majority of cases fall in the Registrar-General's social classes IV or V, and there is little evidence of any relationship to heavy responsibilities or mental stress. Physical stress occurred in less than half the cases.

The mortality was 80%, with sudden death in 74% of the 80 fatal cases.

At necropsy the atheromatous changes in the coronary arteries were similar to those usually described in the older age-groups. A thrombus was found in only 22 of the 80 fatal cases.

The findings support the view that genetic influences are more important factors than habits of life and work

I wish to thank Col F T Rees, Director General of Medical Services of the Ministry of Pensions, for permission to publish

SIMMONDS'S DISEASE (HYPOPITUITARISM) IN A MAN

DUE TO TRAUMATIC HÆMORRHAGE INTO THE PITUITARY GLAND

CHEMICAL PATHOLOGIST

DEPARTMENT OF CLINICAL INVESTIGATION, THE LONDON CLINIC

The following case presented certain features suggesting Simmonds's disease, caused by hæmorrhage into the pituitary gland Simmonds's disease is not common in men, and an acute lesion such as hæmorrhage into the anterior pituitary has rarely been reported

CASE RECORD

A man, aged 44, was admitted to the London Clinic in August, 1947, with an illness which had begun at the age of 39, when he was a brigadier on active service and was leading a vigorous outdoor life At that time he was athletic, and for a height of 71½ in weighed 178 lb

History

He felt absolutely fit and well until Jan 31, 1943, when during a game of deck tennis he jumped to catch a high quoit and felt a sharp crick at the back of his neck, as if a red hot needle had been driven into the nape Momentarily he howled with agony and held his hand to the back of his neck He then tried to continue the game but he began to feel "groggy" and had to stop playing He could not eat dinner, was violently sick and developed a severe headache Throughout the night this headache continued, with vomiting every half hour From midnight to 1 A M he had diarrhœa At 5 30 A M a doctor was called The patient's temperature was then 100°F (37 8°C) and he was feeling very ill At 7 A M he was examined by a medical consultant who ordered his removal to hospital Fluid removed by lumbar puncture was said to be normal He was told that he did not have meningitis or a fractured skull A diagnosis of cerebral dengue was made and he remained in hospital six weeks, spending a further two weeks in a convalescent home

On April 1, two months after the accident, he returned to camp feeling far from well, listless, and lacking in energy He had lost about 28 lb in weight On May 2 he went on sick leave, but on June 2 he was readmitted to hospital because of his failure to improve Encephalitis was tentatively diagnosed, and an attempt to increase his body weight by giving him insulin was discontinued because of coma He remained in hospital for two months After a severe attack of headache and vomiting, lasting eight days, he was again admitted to hospital on Sept 1 His condition deteriorated, and he lost consciousness for about ten days His weight had now fallen to 110 lb, a loss of 68 lb in eight months Recovery from the coma left him exhausted, but at the same time he had a peculiar sense of well being He felt no longer toxic, and he formed the impression that the disease had run its course and that he was going to get better

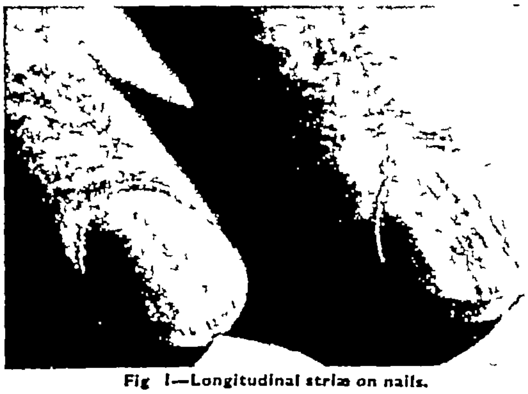

Fig 1—Longitudinal striæ on nails.

There is little of relevance in the later history, except that he had two attacks of pleurisy (February and August, 1944), and that in April, 1944, his teeth, previously in excellent condition, began to loosen and decay, those in the upper jaw being removed He was discharged from the Army in August, 1944, and three months later he returned to civilian occupation His condition remained static until his admission to the London Clinic in August, 1947

Complaints

On admission the patient complained that for the past few years he had lost all energy He tended to collapse after exercise, felt cold easily, had lost much weight, and was subject to severe attacks of headache and vomiting, lasting three days at a time During these attacks he could not eat but craved for water and passed about five litres of urine daily These attacks were said to occur almost regularly every month, and to be so severe that he could not leave his bedroom The last severe attack had been in April, 1947 They were worse in the winter than in the summer

He also complained of constipation, loss of sexual powers, and difficulty in swallowing solid food without sipping liquid His mouth had become dry, with little saliva

Clinical Examination

His height without shoes was 70½ in Before the accident his height had been 71½ in. This apparent loss of height was confirmed by the patient and by his wife and family (three children aged 19, 17, and 15) He weighed 128 lb, being 50 lb (23 kg) below his weight before the accident but 18 lb heavier than he was when his illness passed its acute phase He looked undernourished, and there was a loss of fullness at the terminal phalanges of the fingers, which tended to point, showing an absence of pads The nails were brittle and showed longitudinal striæ (fig 1)

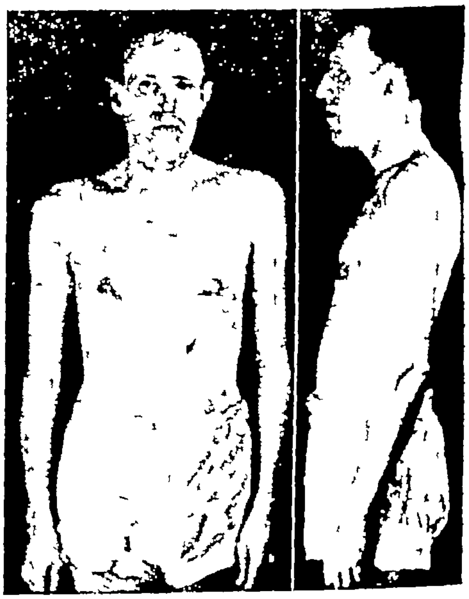

Fig 2—Patient on admission in 1947

Hair—The axillary and pubic hairs were scanty but present as a soft down Before his accident he had had a heavy hard beard, required to shave in the evening if attending any social functions After the accident his beard was soft and he shaved on alternate days The hair of his head had tended to fall out after the accident, and though it was still thick in texture it did not grow so quickly There was considerable thinning of the eyebrows and hair was absent from the outer third of each There was no hair on the first phalanx of each hallux, and hairs in his ears and nose were very scanty, although before the accident it had been necessary for the barber to trim the hair growing in the ears and nose.

The *skin* was dry over the whole of the body

Facies—The patient looked ill and much older than his years (fig 2) His lips were thin and slightly parted His face was expressionless (fig 3) yet distinctive and unlike that seen in any other disease It could be described as mummified or like that of an old man asleep with his eyes open No puffiness was seen under the eyes

Cardiovascular System—The basal pulse rate was 38 (regular) and the basal blood pressure 85/50 mm. Hg Radiographically the heart and aortic shadows were normal. Electrocardiography showed sinus bradycardia with P summits flat in II and III, and T summits inverted in III (fig 4)

Alimentary System—The tongue was clean, and the six teeth in the lower jaw were loose and carious.

Body temperature—97 F (36 C) The thermometer was left in the mouth for six minutes

Radiography—The pituitary fossa was normal in size and shape and there was no radiological evidence of a lesion in the skull. The whole of the spine was examined for evidence of fracture but none was found.

Ophthalmological Report—There were no ocular signs to indicate any abnormality in the central nervous system.

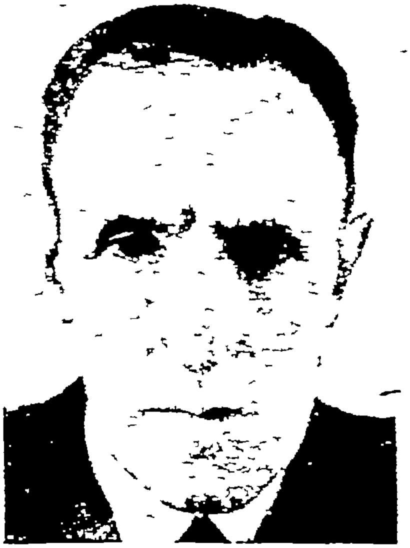

Fig. 3—Expressionless face on admission.

Investigations

Hæmatology—Examination of the blood showed Hb 78% (11 3 g per 100 ml.), red cells 4,050 000 per c.mm., colour index 1 0, white cells 4400 per c.mm. (neutrophils 50% lymphocytes 40% monocytes 6%, eosinophils 4%) The red cells were normochromic but showed slight anisocytosis. The erythrocyte sedimentation rate (E.S.R.) was increased to 31 mm. in 1 hour (Wintrobe)

Serology—The Wassermann reaction of the serum was negative

Relating to the Thyroid Gland—The basal metabolic rate (B.M.R.) was −40 (standards of Aub DuBois) and the blood-cholesterol level 130 mg per 100 ml., suggesting that this was not a case of primary myxœdema, and that the fall in basal metabolism was due to a secondary dysfunction of the thyroid gland.

Relating to the Adrenal Gland—The serum sodium was 355 mg per 100 ml the serum potassium 28 mg and serum-chlorides 585 mg The urinary excretion of chlorides was 9·3 g and of potassium 2 8 g in twenty four hours.

Relating to the Adrenal Gland and the Kidney—The Robinson-Power Kepler index (Robinson et al. 1941) with extension of biochemical investigations, is shown in the accompanying table

After drinking 20 ml. of water per kg of body weight (1160 ml.) the patient passed only 130 ml. of urine—a phenomenon noted by Rosenow (1925) in Addison's disease Estimations of urea and chlorides in the urine showed a concentration of these crystalloids after a large intake of water although the net output per hour fell. All these findings were in complete contrast to those obtained in a normal person (see table) The urea-clearance gave a mean of 67%, a figure not uncommonly obtained in normal healthy people A urea-clearance of 54% was obtained later

Relating to the Pancreas—Several fasting blood sugar estimations on different occasions gave 60–70 mg. per 100 ml. A glucose tolerance test gave the following results

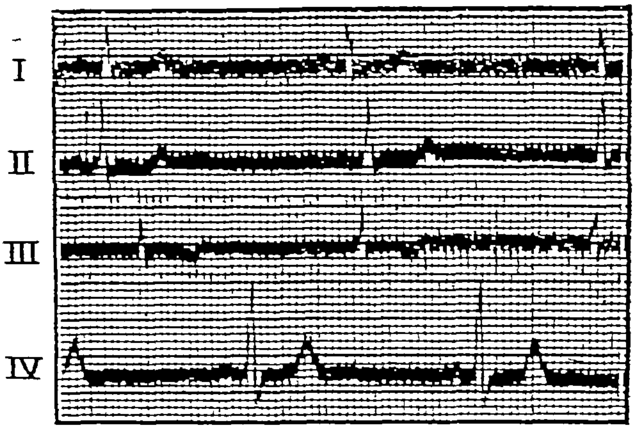

Fig 4—Electrocardiogram showing sinus bradycardia, P summits flat in II and III and T summits inverted in III

Resting blood sugar	70 mg per 100 ml
½ hour after glucose 50 g	110 mg ,,
1 hour	100 mg
1½ hours	65 mg
2 hours	60 mg

It was decided not to proceed with the standard (Fraser and Smith 1941) insulin tolerance test in view of the previous history of hypoglycæmia and the low fasting blood sugar level (This fortunate decision will be discussed elsewhere Recently, in a case of Simmonds's disease the intravenous injection of insulin 0·03 unit per kg of body-weight brought on severe hypoglycæmia with a blood sugar level of 15 mg per 100 ml in twenty five minutes and large doses of glucose by mouth did not prevent coma.)

Hormone Excretion—The excretion of 17 ketosteroids was less than 1 mg in twenty four hours

Gastric Function—A fractional test-meal showed a concentration of free hydrochloric acid reaching a maximum of the equivalent of 57 ml of N/10 NaOH and an emptying time of 1½ hours

Renal Function—Three hours after the drinking of 1 litre of water 105 ml. of urine contained 2 08 g of urea per 100 ml

ROBINSON POWER-KEPLER INDEX AND OTHER FINDINGS

Time	Urine

NORMAL CONTROL	26	580	229 0
PATIENT	30	580	3 2

and the blood urea level was 35 mg per 100 ml, giving a normal urea clearance of 84%, impairment of water elimination being compensated for by a high concentration of urinary urea A urine concentration test gave the following figures

Time (A M)	*Volume* (*ml*)	*Sp gr*
6 30	530	1 014
7 30	415	1 012
8 30	70	1 020

The very restricted fluid intake caused no concentration of the urine, but instead urine with a diminished specific gravity was passed A urea concentration test gave the following figures

Specimen	*Volume* (*ml*)	*Urinary urea* (*g per 100 ml*)
Resting	26	1 3
	Ingestion of urea 15 g	
1 hour	60	2 3
2 hours	50	2 7
3 hours	52	2 1
4 hours	55	2 1

Treatment

After preliminary treatment with graduated doses of deoxycortone acetate, testosterone propionate, and thyroid gland for five weeks, and a high intake of salt and glucose, 400 mg of deoxycortone acetate and 400 mg, of testosterone propionate was implanted into the anterior abdominal wall

Progress

Two months after treatment was begun, the patient's condition had improved He weighed 140 lb, a gain of 12 lb (5 5 kg) The B M R was −19, the basal pulse rate 50, and the blood pressure 140/90 mm Hg The urinary excretion of 17 ketosteroids was 4 6 mg, of potassium 4 7 g, and of chlorides 9 9 g in twenty four hours Plasma chlorides 620 mg, serum sodium 355 mg, and serum potassium 23 mg per 100 ml The fasting blood sugar remained low, about 70 mg per 100 ml There was no change in the blood picture, but the E S R had fallen to 20 mm in 1 hr (Wintrobe)

The patient felt very much better, and said he had never felt so well since the accident He could walk two or three miles without fatigue For business reasons he had to return home after treatment had been in progress two months

Follow up—A note from him three months later said he was feeling almost normal and was driving his car, which he had been unable to do since the accident, driving as much as 200 miles a day without fatigue He has had no more attacks of headache, sickness, and vomiting since treatment was started Advice was given that reimplantation every six months might be necessary, according to his clinical condition

DISCUSSION

Simmonds's disease is not very common in the male It was some ten years after Simmonds * (1914) first described a case in a woman that Lichtwitz (1924) described a similar condition in a man Lichtwitz also suggested that the name "Simmonds's disease" be given to the pathological syndrome that Simmonds (1916) in his third communication had called "cachexia of hypophyseal origin," because, according to Lichtwitz, as a result of different degrees of damage to the pituitary gland, a varied clinical picture was found

Simmonds's disease caused by trauma has only rarely been reported There are two main causes a fractured skull and a bullet wound

Five, possibly six, cases due to a *fractured skull* have been reported (Cyran 1918, Reverchon et al 1921, Schereschewsky 1927, Berblinger 1934, Lisser and Curtis 1945, and possibly Lerman and Means 1945, case 2)

Two cases of *bullet wounds* of the pituitary gland have been reported Frank's (1912) case was questioned by Leschke (1919), who saw the X ray films and said that the bullet was lodged above the sella turcica Further, signs of damage to the anterior lobe of the pituitary gland were not clearly described Lerman and Means's (1945) case 1 is clear cut, and all the signs and symptoms of Simmonds's disease developed shortly after the accident

A further possible cause of Simmonds's disease is hæmorrhage into the pituitary gland De Costobadie and Ryrie (1924) described a case with an extensive hæmorrhage into the pituitary, but it was the hæmorrhage and not the Simmonds's disease that caused death.

The history is vague, but during the previous year the patient, a man aged 49, had complained of headache, failing vision, and hairlessness (which takes time to develop) The patient died six weeks after the acute lesion, during which time he was practically comatose At necropsy the pituitary showed a recent hæmorrhage, causing the pituitary, five times its normal size, to bulge up outside the sella turcica, and there was clear evidence of encephalitis lethargica

Our case presented all the signs, symptoms, and laboratory evidence typical of true Simmonds's disease The history and the findings at the time of the accident make it clear that there was an acute trauma, and that probably the lesion was a hæmorrhage into the pituitary gland, involving chiefly the anterior lobe With improvement in clinical and laboratory diagnosis it seems reasonable to diagnose Simmonds's disease at an early stage, thanks mostly to Sheehan (1939, 1940, 1948) and his colleagues (Sheehan and Summers 1949, Cooke and Sheehan 1950), who have pointed out that many cases of emaciation are misdiagnosed as Simmonds's disease

The differential diagnosis seemed to be between anorexia nervosa, Addison's disease, myxœdema, and Simmonds's disease Against anorexia nervosa were the sudden onset, the extreme weakness and reduction of activity, the normal appetite, the patient's age, the very low 17 ketosteroid excretion, and the loss of hair and teeth Against Addison's disease were the lack of pigmentation of the body and mucosæ, the normal plasma chloride and serum sodium levels, the normal excretion of urinary chlorides and potassium, and the bradycardia Against myxœdema were the low blood cholesterol level and other biochemical observations Thus Simmonds's disease was the most probable, and in favour of this were the sudden onset following an accident, the typical signs and symptoms, the failure of function of the thyroid, adrenals, and gonads, and the degenerative changes in hair, skin, and teeth

The tests commonly used showed no renal impairment, but an attempt to concentrate the urine by the usual procedure of Volhard as modified by Fishberg (1939) failed, leading to a large output of urine of low specific gravity—the opposite of what happens in normal people With the increased concentration of urinary urea and chlorides and diminished urine output following the ingestion of a large amount of water, it is tempting to postulate, in the present case, an increased accumulation of an antidiuretic substance (A D S) Our finding not dissimilar from those obtained by Birnie et al in a study of the A D S in normal and in adrenalect rats The A D S may act by increasing tubular reabsor tion of water or diminishing glomerular flow If, as Birnie and his colleagues suggest, the A D S has its origin in the posterior lobe of the pituitary, the lesion in our case affected only the anterior lobe

The insulin tolerance test, even when done w but small an intravenous injection of insulin as 0 03 u kg of body weight, is not without risk, a da hypoglycæmia can develop, the blood sugar level from 75 to 15 mg per 100 ml in twenty five m even when the procedure of Engel and Scott (1949), designed to prevent hypoglycæmic coma by giving glucose by mouth half an hour after intravenous insulin 0 1 unit per kg of body weight, is used

---

* Simmonds is given the credit for being the first to draw attention to a clinical syndrome due to post partum necrosis of the pituitary gland, afterwards limited by Fraenkel (1916) to the anterior lobe An abstract of a paper by L K Glinski of Poland, published in 1913 has been found in which he described three cases of pituitary necrosis following puerperal sepsis An attempt is being made to trace the original paper or papers, and these may show that Glinski anticipated Simmonds (Robertson 1951)

SUMMARY

A case of Simmonds's disease in a man was caused by an acute lesion, probably due to hæmorrhage, in the pituitary gland No similar case has been traced

The patient improved considerably on treatment with deoxycortone acetate, testosterone propionate, and thyroid gland

It is a pleasure to thank Mr A V Bridgland, chairman of the Trustees of the London Clinic for generously providing all facilities for this investigation, Mr J A Roberts for much technical assistance, Dr M Frisch for assistance in translations, and our patient for his most willing coöperation

METHÆMOGLOBINÆMIA DUE TO SODIUM NITRITE

T E OPPÉ
M B Lond, M R C P
LATE CHILDREN'S HOUSE PHYSICIAN, GUY'S HOSPITAL, LONDON

CYANOSIS in infancy is usually due either to congenital heart disease, or to respiratory-tract disease caused by congenital malformation, obstruction, or infection Occasionally cyanosis is due to alteration in hæmoglobin with methæmoglobinæmia or sulphæmoglobinæmia

In the case described here cyanosis was due to sodium-nitrite poisoning

CASE RECORD

A male baby, aged 2 months, was admitted to Guy's Hospital with cyanosis of 3 hours duration He was the only child of healthy parents, and there was no history of cyanosis in the family He had been delivered by forceps at home His birth weight was $7^{3}/_{4}$ lb, at birth he cried vigorously, and was not cyanosed He was breast-fed for 10 days and then put on bottle feeding Owing to mild dyspepsia—wind and colicky pain—the parents had been advised to give [illegible] sodium citrate gr 4 at each feed On the evening before [illegible]sion a new supply of tablets had been obtained from [illegible]emist and two tablets of this new supply were used for [illegible]ly morning feed on the day of admission

At 7 A.M he had a normal feed with two tablets added to it this he took well At 8 20 A M he went "almost black", there was some retching but no vomiting The cyanosis persisted soon the hands and feet became blue, and at [illegible]0 A.M. he collapsed with drowsiness and rapid respirations [illegible] was immediately taken to the local practitioner, who [illegible] him collapsed and duskily cyanosed, with tachycardia [illegible] hypnœa

[illegible]dmission at 12 30 P M the child had a peculiar slate [illegible]anosis unlike that of congenital heart-disease He did [illegible]ear distressed and had no pyrexia There was only slight dyspnœa, and no signs of respiratory obstruction. Examination of the chest and cardiovascular system disclosed no abnormality The abdomen was soft and the liver and spleen were not palpable There was no neck rigidity, and the fontanelle was normal

Toxic methæmoglobinæmia was diagnosed, and the remaining tablets, which the mother had fortunately brought, were sent for analysis

The baby was placed in an oxygen tent, which did not relieve his cyanosis, and the stomach was washed out with sodium bicarbonate, since potassium chlorate poisoning was suspected

Blood examination Hb 61% (Haldane), red cells 3,200,000 per c mm, with no nucleated red cells Spectroscopy of a solution of whole blood after hæmolysis showed the characteristic absorption band of methæmoglobin, confirmed by its disappearance after the addition of alkali It was later reported that the tablets each contained sodium nitrite gr 1, the amount ingested therefore being gr 2—the amount named in the *British Pharmacopœia* as the maximum dose for an adult

That evening cyanosis was still present, although less severe, blood that was withdrawn was brownish 0 3 ml of a 5% solution of methylene blue was injected intravenously *Immediately the baby's colour became chocolate brown* but during the next 20 minutes his colour returned to normal

Cyanosis did not recur, and the patient was discharged, well, 5 days later

DISCUSSION

Toxic methæmoglobinæmia in infancy and childhood, which is not uncommon, should be considered in all cases of unexplained cyanosis Lately this condition has received much attention because of outbreaks associated with nitrate-contaminated well water or aniline derivatives in marking ink Isolated cases of methæmoglobinæmia, due to accidental absorption of other toxic compounds, occur occasionally in infants and children

Nitrite poisoning has been previously reported in a girl, aged 5 years, who, with her mother and father, ingested a large quantity of sodium nitrite in mistake for table salt, with a fatal outcome (McQuiston 1936) Roe (1933) reported several cases of methæmoglobinæmia in infants treated with bismuth subnitrite, with one death

Aniline derivatives are used in the manufacture of some wax crayons, and acute methæmoglobinæmia has been caused in children by their ingestion (Jones and Brieger 1947, Clark 1947) An interesting case in a schoolboy of 14, who accidentally came into contact with pure aniline during a chemistry lesson and suffered from almost fatal poisoning, is described by Sterning (1951)

Poisoning with nitrobenzene has been reported in twins, aged 3 weeks, by Stevens (1928), the source was a proprietary disinfectant used to kill bed bugs in the children's mattress Leader (1932) described a case of toxic methæmoglobinæmia in a 20 month old girl, the cause was poisoning with nitrobenzene mistakenly prescribed for almond oil, and the patient was treated successfully by exsanguination transfusion

The clinical picture of slate grey cyanosis, collapse, and vomiting without evidence of respiratory or cardiac disease should suggest methæmoglobinæmia If the cyanosis is unrelieved by oxygen therapy, and blood withdrawn from a vein shows the characteristic chocolate-brown coloration, the diagnosis is certain Methylene blue 1–2 mg per kg body-weight should at once be injected intravenously, and the causal substance must be sought and eradicated

SUMMARY

An infant with cyanosis due to accidental sodium-nitrite poisoning was successfully treated by intravenous injection of methylene blue

I wish to acknowledge gratefully Dr R C Mac Keith's interest in this case, and his help and encouragement in preparing this report

HYPERPYREXIA WITH CEREBELLAR DAMAGE IN ACUTE RHEUMATISM

ERIC K CRUICKSHANK
M D Aberd, M R C P
LECTURER IN MEDICINE IN THE UNIVERSITY OF ABERDEEN

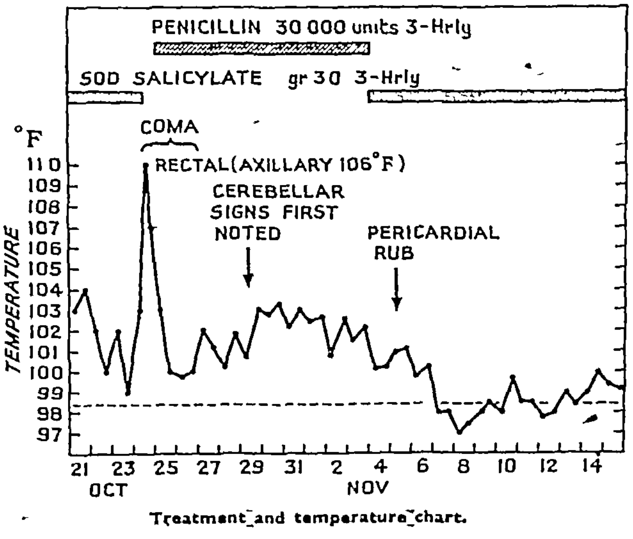
HYPERPYREXIA seems nowadays to be rare as a complication of acute rheumatism, but it was quite familiar to the physicians of the latter part of last century So far as I know, cerebellar damage following hyperpyrexia has not been recorded in rheumatism, although it is a recognised sequel to the hyperpyrexia of heat stroke The case reported here presented both these features

CASE RECORD

A tractor driver, aged 20, was admitted to Woodend Hospital, Aberdeen, on Oct 21, 1948, with the history that he had been fit until six weeks before admission, when he had had a sore throat, which had lasted two or three days He had been well again until fourteen days before admission, when he had had a recurrence of sore throat with some swelling of the neck glands Seven days later he had developed pain in the right shoulder Thereafter pain and stiffness had occurred serially in the right elbow, right wrist and fingers and on the day before admission both knees had become swollen, stiff, and painful He had been sweating profusely He had received sulphapyridine 7 g from his own doctor

On examination he was a well built man with a flushed face and injected conjunctivæ and was sweating profusely His temperature was 103°F His right wrist and elbow were swollen and painful There was some limitation of abduction of the right shoulder, some pain on flexion of the right hip, and stiffness of both knees, especially the left The heart-rate was 76 The apex beat was palpable 4 in from the mid sternal line in the 4th left intercostal space, and a soft systolic murmur was audible at the apex The blood pressure was 138/46 mm Hg These findings were not regarded as indicating active carditis No abnormalities were demonstrable in other systems He was bright and coöperative His speech was slow, but his voice and articulation were normal A white cell count showed 19,450 per c.mm, and the erythrocyte sedimentation rate (E S R) was 115 mm in one hour (Westergren) The urine contained albumin, numerous pus cells, a few red cells, and some hyaline casts A blood culture was sterile Urine culture was not done The patient therefore presented a classical picture of a moderately severe case of acute rheumatism with a low grade urinary infection

Treatment —He was treated with sodium salicylate gr 30 three hourly and an alkaline mixture of potassium citrate and sodium bicarbonate, āā gr 30 four hourly, with a high fluid intake



Treatment and temperature chart.

Progress —During the next three days the joint pains almost went, the temperature was settling, and the abnormal urinary findings disappeared But on the morning of the fourth day after admission the patient complained of a black cloud in front of his eyes and buzzing noises in his ears, and said he felt funny and that "it was the last" Salicylates being thought to be responsible, the next dose was omitted That afternoon at 4 15 P M the patient got out of bed and stood waving his arms about and talking incoherently He was put back to bed and lay smiling, grimacing, and screwing up his eyes There was occasional rhythmical twitching of his arms, lasting a few minutes The axillary temperature was 106°F and rectal temperature 110°F He next developed generalised clonic movements going on to intermittent tonic spasms with arching of the back Between spasms he was deeply comatose, with widely dilated fixed pupils, flaccid limbs, absent reflexes, and extensor plantar responses

The windows were opened The patient was stripped and wrapped in sheets dipped in cold water Oxygen was administered and nikethamide 6 ml given intramuscularly These measures reduced the rectal temperature to 104°F and were continued for the next twelve hours Lumbar puncture produced a clear fluid not under pressure and containing protein 30 mg per 100 ml and no increase in cells

The patient remained comatose during the night, but his blood pressure rose to 100/70 mm Hg, with a pulse rate of 110 Occasional clonic twitching of the arms and legs continued As he could not swallow he was given 8 pints of glucose saline solution intravenously during the next forty eight hours On the evening of Oct 25, 1948, he mumbled something to the night nurse, and by the morning of Oct. 26 he was conscious, but his speech was slow and mumbling He was moving all his limbs, the deep reflexes were brisk and equal, and the plantar reflexes flexor Unfortunately his central nervous system was not fully examined until Oct 29, when scanning speech, a gross intention tremor of both arms, and incoordination of the legs were found There was no nystagmus and no evidence of damage to the sensory system or the upper and lower motor neurones

The patient continued to have fever for thirteen days after the hyperpyrexial attack (see figure) Penicillin 1,000,000 units in ten days was given to prevent a respiratory infection Sodium salicylate was withheld for ten days because it was regarded as possibly responsible for the hyperpyrexia It was given again on the tenth day after the hyperpyrexial attack, and the temperature fell to normal in three days A transitory pericardial rub was noted on Dec 5, 1948 The intention tremor of the arms and incoordination of the legs gradually disappeared in the next three weeks, but the speech disorder persisted

During the next three months the patient had three recrudescences of the rheumatic infection, there was a pericardial rub and a transient diastolic murmur during one episode, and another was associated with a patchy consolidation of the left lower lobe

Thereafter the E S R remained below 3 mm in one hour, and there was no clinical evidence of permanent cardiac damage The speech remained slightly scanning A brother said he had not noticed any mental changes since the illness, but the patient's speech was slightly but definitely altered There was no evidence of ataxia or incoordination of the limbs when he was last reviewed in June, 1949, and he had again been working as a tractor driver for six months

DISCUSSION

Hyperpyrexia was such a common and dramatic complication of acute rheumatism in the last century that in 1879 a special committee of the Clinical Society of London was nominated to investigate it Their detailed report (Committee on Hyperpyrexia in Rheumatic Fever 1882) reviewed 67 cases in various London hospitals in 1871–80 They found that hyperpyrexia was commonest in first attacks of rheumatic fever, where it might suddenly supervene in apparently favourable cases, and that half the patients died At that period salicylates were not in general use in the treatment of rheumatic fever, this therapy was first used in this country by Maclagan in 1874, and he did not publish his results until 1876 It therefore seems likely that salicylates have been mainly responsible for the extreme rarity of hyperpyrexia in rheumatic fever in recent years

The committee described among the neurological manifestations muscular tremors, tonic spasms, convulsions, a silly manner, and hesitating speech, all of which were features of the present case in the early stage, but they did not mention signs of cerebellar damage persisting after recovery

Destruction of the cells of the hypothalamic nuclei in heat stroke have been demonstrated by Morgan and Vonderahe (1939) There is good evidence that these cells, among other functions, act as the thermostat of the body, and damage to them may produce gross disturbance of temperature regulation It is therefore reasonable to assume that the hyperpyrexia of acute rheumatism is the result of damage to these cells from the encephalitic changes which may complicate that disease Winkelman and Eckel (1932) reviewed these changes and concluded that they were not greatly different from those occurring in any severe infection Frisch (1934) reported a case of rheumatic encephalitis complicating a typical attack of rheumatic fever, which had initially responded to salicylate therapy

Seventeen days after admission signs of severe chorea with maniacal outbursts developed. The temperature was 103–106°F and later rose to 108 4°F when the patient became comatose and cyanotic The cerebrospinal fluid was under slightly increased pressure and contained an increased amount of globulin and 70 cells per c.mm , 80% of which were lymphocytes. Signs of diffuse brain damage with maximal involvement of the basal ganglia appeared thereafter These gradually disappeared, and eight weeks after the onset no abnormality was demonstrable in the nervous system

Alpers (1928) and Dobbs and de Saram (1938) describe acute hæmorrhagic encephalitis in acute rheumatism

The patient of Dobbs and de Saram was a girl, aged 8 years, with moderately severe rheumatism who, after responding satisfactorily to salicylates, suddenly developed nervous symptoms and hyperpyrexia (108°F) and died in coma eighteen hours later Histological examination of the brain showed numerous small and large ball and ring shaped hæmorrhages scattered generally throughout the substance None of the changes were regarded as specific to acute rheumatism.

Bourne (1936) and High and Aegerter (1945) record cases of acute rheumatism with features of meningo-encephalitis, but none of them mentions clinical or histological evidence of damage to the cerebellum Lhermitte and Pagniez (1930) and van Gehuchten (1931), however, noted predominant lesions in the dentate nucleus and Purkinje cells of the cerebellar cortex in patients dying in the course of acute chorea

Changes in the cerebellum as well as elsewhere in the brain have been demonstrated histologically in fatal cases of heat stroke, and the damage may be maximal in the region of the Purkinje cells (Brouwer 1913, Schwab 1925, Hartman 1937, Freeman and Dumoff-Stanley 1944)

Nonne (1907, cited by Weisenberg 1912) gave one of the first clinical records of cerebellar damage following heat-stroke Weisenberg (1912) described a patient who had gross ataxia of the limbs head, and tongue after coma with a temperature of 107°F due to heat-stroke Nystagmus was not present Stewart (1918) gave details of another case where the temperature reached 109 2°F and was accompanied by clonic convulsions and deep coma After recovery gross incoördination of the limbs nystagmus, and mental deterioration were still present sixteen months later Clinical evidence of gross cerebellar damage without nystagmus was also found by Freeman and Dumoff Stanley (1944) in a patient whose axillary temperature had reached 108°F

McAlpine (1946) gives a brief account of three soldiers who had recovered from heat-stroke All three were dysarthric and showed ataxia and unsteadiness in walking None showed nystagmus. In two the signs cleared in a few weeks, but in the third they persisted McAlpine describes a further case presenting features very similar to those seen in advanced disseminated sclerosis , the patient had made no improvement two months later

It is therefore apparent that in some people the cells of the cerebellum are particularly susceptible to damage from hyperpyrexia, and such damage may be temporary or permanent In the published cases the cause of the hyperpyrexia has been "heat stroke" In our patient the hyperpyrexia occurred during acute rheumatism and was probably due to damage to the nuclei of the hypothalamus from the encephalitic changes that may take place in acute rheumatism An unusual toxic action of sodium salicylate may have been responsible, but no such toxic action has been reported Moreover hyperpyrexia has become a very rare complication in acute rheumatism since the introduction of salicylates as the routine remedy, and in our patient pyrexia continued when sodium salicylate was withheld, but rapidly disappeared when sodium salicylate was given again The only evidence of any permanent damage to the central nervous system in this patient is the persistence of some hesitancy of speech

SUMMARY

A case of acute rheumatism complicated by hyperpyrexia is described

After the patient had recovered from the resultant coma, signs of cerebellar damage were demonstrable These signs disappeared in three weeks, but some hesitancy of speech persisted

A C T H IN DERMATOMYOSITIS

REPORT OF A CASE

A ALUN WILLIAMS
M.D Lond , M.R C.P.E
ASSISTANT PHYSICIAN

D P BOWLER
M.D Lond , M.R C.P.
LATE REGISTRAR

NUMBER TWO MEDICAL CLINIC TEES SIDE HOSPITALS

DERMATOMYOSITIS is classified as one of the collagenoses Dowling (1950) states that nothing is known of its ætiology, and classifies it with the sclerodermas In 1939 he drew attention to the presence of lymphorrhages in the muscle, and to a possible relationship with thyroid disease (Dowling 1940)

O'Leary (1949) holds that the most probable cause is infection culture of the affected muscle during an acute phase has revealed streptococci, staphylococci, or both, and occasionally a vaccine made from the organisms cultured has led to improvement He thinks that the histological changes in the muscle are inflammation (this may correspond to the lymphorrhages of Dowling) followed by degeneration

According to Selye (1950) dermatomyositis is one of the many manifestations of the adaptation syndrome and responds to adrenocorticotropic hormone (A C T H).

CASE RECORD

A married woman aged 34, was admitted to hospital on March 15, 1950, with eighteen months history of shortness author's obvious enthusiasm for his operation, and his minute description of preoperative and postoperative treatment, are delightful The opinions of any expert, writing on his own subject, are all the more interesting when he compares his own methods and results with those of others Professor Hryntschak has obviously absorbed every detail of Harris's work and more recently that of Millin, and put it to very good effect All urologists will derive pleasure from reading this detailed book and may learn much from it It is a pity that the publishers have included advertisements in the text and have relegated the illustrations to an envelope within the back cover

Conference on Problems of Aging

Editor Dr NATHAN W SHOCK New York Josiah Macy, Jr, Foundation 1950 Pp 258 $3 75

AT present, when so many doctors in Great Britain are considering the processes of ageing, it is interesting not only to learn something of the ideals and work of the Josiah Macy Foundation in gerontology, but also to appreciate the wide field reviewed at this conference Subjects ranged from scientific details of research methods, on the one hand, to matters of principle, or practical policy, in developments of geriatric services on the other, and the speakers spoke with authority

Most of the discussions were scientific, relating to biological research on regeneration of the liver in old age, sexual regeneration in elderly women, nutritional factors, long term hæmorrhage anæmia in dogs, life span experiments with rats, and like subjects Others dealt with social problems such as the age of retirement, and with the organisation of research units in gerontology, and the chances of coöperation between gerontological societies in Europe and America Discussions started all manner of fascinating hares, among them the recruitment of young people for work in geriatrics, the development of geriatric services in connection with hospitals, and the psychology and psychiatric care of the old The volume should be widely read, not only for information but for the vigorous exchange of ideas it presents

Terminal Care for Cancer Patients

WILLIAM F PETERSEN, M D, chairman of the advisory committee, Central Service for the Chronically Ill Chicago, Ill Institute of Medicine of Chicago Pp 211

THIS is the record of an inquiry by a specially appointed "survey staff" into "the facilities and services available and needed for the terminal care of cancer patients in the Chicago area," made in 1947–49 The field work was clearly excellent the facts disclosed have been recorded and correlated and the problems that emerged are thoughtfully and imaginatively considered The report itself is less admirable long words, awkward or obscure phrases, and much repetition make tedious reading of what should be a stimulating recital of facts to be faced None the less it deserves to be read and considered, and the work might well be repeated in some comparable district here

The survey distinguishes between the "terminal phase" of a cancer—the phase in which curative treatment is no longer possible and the disease is progressing towards death—and the "terminal carestage," in which the patient can no longer fend for himself It is with the latter that the writers are mainly concerned, though they observe that, despite the new therapeutic weapons, the average length of the terminal phase has not increased since 1921 The average length of the terminal care stage, as determined in this survey, is 93 days It varies with the site of the growth from 66 days' average for respiratory to 631 days for skin cancers For every four cancer deaths per annum in a community one patient, at any given time, is needing terminal care, and he needs an average of 4 hours' bedside care a day 20% of all cancer patients, these workers find, can remain at home to the end and prefer to do so The 80% who die in hospital will on an average, spend over half the terminal care stage at home, so at any one time about two-thirds of these patients will be at home and needing some care there. As to the kind of care, it is often as much housekeeping as nursing, and the nursing needed is often very simple The report urges that "practical nurses" and nurse housekeepers should be trained and made available in much greater numbers than at present their usefulness would extend far beyond the terminal care of cancer The provision of special homes or hospitals for late cancer is roundly condemned, and the writers find with satisfaction that general hospitals would willingly accept these patients if they had the beds The formidable financial difficulties of making appropriate or acceptable provision for them are examined in detail, as are the equally formidable emotional difficulties, due largely to misconceptions about the clinical features of cancer in its commoner forms

A final chapter gives an encouraging account of recent progress towards adequate provision for these unhappy patients in and about Chicago, but it is clear that there is still a long way to go Whether things are better or worse in this country probably only a similar survey could show

---

British Encyclopædia of Medical Practice (2nd ed London Butterworth Medical Publications 1951 Vol 5 Pp 680 £3)—Publication of the new edition of this important work is proceeding apace, the fifth volume, which sustains the high standard of its predecessors, carries forward this alphabetically devised compendium from Ecthyema (by Dr J E M Wigley and Dr O L S Scott) to Gassing and Poison Gases (by Lieut Colonel C A de Candole) This volume includes an unusually clear exposition, by Sir Adolphe Abrahams, of Etiquette and Ethics in medical practice

A Manual of Psychiatry (Christchurch, N Z N M Peryer 1950 Pp 294)—The work of Dr K. R Stallworthy, medical superintendent of Porirua Hospital, this textbook of psychiatry covers the syllabus for the New Zealand psychiatric nurse but should also prove of value to students and general practitioners in the Dominion It is clearly written, and the attitude to the patient which it both enjoins and exemplifies is altogether admirable

A Complete Outline of Fractures, including Fractures of the Skull (3rd ed London Heinemann *Medical* Books 1951 Pp 671 42*s*)—Mr J Grant Bonnin's justly popular textbook has reached its third edition without any serious increase in girth His deliberate attention to the needs of undergraduate and postgraduate students has kept him, as he says in the preface, from including exuberant detail, or "the peculiar fractures which appeal to the connoisseur" Instead, he has revised some judgments, added to the illustrations, and put in new matter about such things as the Küntscher nail, the operative treatment of hand and finger injuries, and streptomycin The line drawings are his own, and show him as an excellent draughtsman

Clinical Parasitology (5th ed London Henry Kimpton 1951 Pp 1032 84*s*)—Colonel C F Craig and Prof E C Faust have sifted the vast amount of information published on medical parasitology since their fourth edition, and present the results in this completely revised volume New drugs for the treatment of malaria, filariasis, and several of the diseases transmitted by arthropods, and new insecticides for slaughter of the transmitters, have been given due space and Prof Albert Miller contributes a chapter on the control of 'medically important arthropods" which reminds readers that this phylum includes such large direct attackers as scorpions, centipedes, and biting spiders as well as those smaller trouble bearers, lice, mites, and the like

Doctors of the Mind (London Robert Hale 1950 Pp 327 15*s*)—This book has the subtitle "The Story of Psychiatry", and a very dramatic story Miss Marie B Ray has made of it She has evidently read widely, and she acknowledges the help of no fewer than 27 psychiatrists whom she has interviewed or consulted. She begins by tracing the evolution of mind from the unicellular organism to the primates, describing Kohler's work with apes and then Broca's discovery of the speech centre, and going on to Mesmer and the later hypnotists, and the growth of psychotherapy, via Charcot, Bernheim, and Liebault to Freud Adler, and Jung A full account is given of physical methods of treatment from Wagner-Jauregg to Meduna, Sakel, and Davidoff The style is colourful and over optimistic, and weighty problems are over simplified but the material is all there

THE LANCET

LONDON SATURDAY, MAY 12, 1951

More Discretion for Hospitals

IN his report[1] accompanying the summarised accounts of the National Health Service for 1949–50 Sir FRANK TRIBE, the Comptroller and Auditor-General, remarks that some hospital authorities had not adjusted, or had declined to adjust, salaries in excess of the approved scales He goes on to say that the Ministry of Health tells him that, as a number of boards have not complied, the question of making regulations under section 66 of the National Health Service Act is being considered

The brevity with which the matter is handled in Sir FRANK's report lends colour to the opinion expressed in the press—that here we have a simple clash between the principle of central control and some recalcitrant hospitals But actually the position is probably more complex Judging by the few instances of which something has been heard, the point at issue is whether hospitals may use their free moneys to supplement salaries Some hospitals have sought permission to supplement certain salaries out of their free moneys, honestly believing that such a course would be in the public interest, but this permission has been refused, no doubt because the Ministry foresees a chaotic state of affairs and is apprehensive of wholesale evasion of the centrally regulated salary scales Nettled by this refusal, relying on the undoubted general intention of the Act that hospitals should be encouraged to accept real responsibility for their own affairs, and conscious of the extent to which they themselves control public moneys, some hospitals have paid, or continued to pay, the excess out of public funds It seems a pity that no compromise has been found possible, and for our part we should feel happier if we knew from the Ministry whether any via media has been seriously considered For example, where a hospital can find the money to do so, might it not be allowed to supplement the salaries of certain senior officers by a sum not exceeding such and such per cent of their salaries —subject, if necessary, to the Ministry's explicit approval in the particular circumstances, and also perhaps subject to compliance with certain known conditions, of which length of service with the hospital might be one? Would it not be very much in the general interest to allow this degree of discretion to the employing authority, so that a man would feel some sort of debt to his board and the board in turn enjoy a slight, but valuable, hold over its servant?

As matters stand—or will stand if the threatened regulation is made—the hospitals will be brought into line with the Civil Service This solution should not, we think, be tamely accepted The analogy with the Civil Service is far from complete, indeed, it is little more than superficial The individual hospital authorities are not branches of a Department, but separate units with power to appoint and dismiss, and the status of their officers is quite unlike that of a Civil Servant who is promoted from one post to another throughout his career There are other branches of the public service where rates are centrally negotiated—as for example the recently published scales for chief officers of local authorities—where a real and important discretion is allowed to the local unit In that field it has obviously been thought important not to destroy by uniformity the element of dependence of the officer on the good opinion of his authority, with all the incentive that is involved therein. In the hospital world very similar circumstances apply, and some sort of inquiry into the principles involved is desirable before the matter is settled We are, or should be, concerned not so much with avoiding trouble today as with devising a plan which will make for the excellence of the service tomorrow

[1] Report of the Comptroller and Auditor General on National Health Service Accounts H M Stationery Office Pp 37 1s 3*d*

The Influenza Virus

"I could be bounded in a nut shell, and count myself a king of infinite space"

Sir MACFARLANE BURNET takes Hamlet's words for his text in the Herter lectures for 1950[1] His theme is Some Biological Implications of Studies on Influenza Viruses, and he attempts to show how the detailed study of a nutshell can provide us with knowledge of infinite space—not a simple task in this expanding universe

The first lecture describes the process of infection by influenza viruses Understanding of the initiation of influenza infection is due in large part to the work of HIRST in America and of BURNET and his colleagues in Australia HIRST[2] noticed that when allantoic fluid from chick embryos infected with influenza virus was mixed with chick blood, the red cells became agglutinated He was quick to appreciate that this would provide not only a most valuable laboratory technique for measuring the concentration of influenza virus and antibody, but also a model, suitable for study in test-tubes, of the method which the influenza virus adopts in order to enter respiratory cells BURNET describes how the Australian workers started with the red-cell model and then adapted their results to the study of the early processes of infection in the fertile egg and the mouse Largely as a result of this work, the "receptor substance" on red cells to which the virus adheres has been shown to be a mucopolysaccharide An enzyme from *Vibrio cholerae* filtrates, usually known as R D E (the receptor-destroying enzyme), can inactivate the receptor substance on red cells so that influenza viruses can no longer be adsorbed STONE[3] has shown that R D E will also prevent the adsorption of influenza virus to the cells lining the allantoic cavity and the respiratory tract of the mouse In these sites, R D E can therefore prevent influenza infection from making a start Once the virus has entered the cells, however, it is no longer susceptible to attack by agents of this type, so let us leave the nutshell and join BURNET in his attack on the kernel.

The second lecture deals with reproduction and variation in influenza viruses, and the lecturer adopts a genetic approach to the problem of how the influenza virus multiplies Recent work on bacterial virus genetics has introduced the disciplines of mathematics into what was once considered a biological field But the application of similar techniques to animal virus genetics meets with many difficulties It is comparatively simple nowadays to study the behaviour of a single bacterium infected with a single bacteriophage particle, but it is not yet possible to examine isolated animal cells in this way This has not deterred **Burnet** from tackling the problems of virus genetics, and he summarises the results of recent investigations for us Details of the work have lately been published[4] Of great interest is the demonstration of combination of characters of two similar viruses—a sort of hybridisation Two strains of influenza virus were injected together into mice intracerebrally—e g, strain NWS which has neurotropic properties and MEL which is non neurotropic Under certain conditions it was possible to isolate virus with the neurotropic properties of NWS and the serological characters of MEL Control experiments failed to show that MEL produced neurotropic variants spontaneously One possible explanation is that the phenomenon is analogous to the transformation of serological types of pneumococci Recently it has been shown that a desoxyribonucleic acid fraction, isolated from type 3 pneumococci, is capable of conferring type 3 specificity on a pneumococcus of another type The new hereditary characters are then maintained in the absence of further added desoxyribonucleic acid A second possibility which **Burnet** favours, is the hypothesis advanced in order to explain recombination of virus characters in bacteriophages It is suggested that the influenza virus particle, on entering the infected cell, breaks up into a number of discrete genetic units, that these replicate independently, and that towards the end of the period of multiplication they recombine to form complete virus particles Such a hypothesis proposes a basically different method of multiplication of viruses from that of bacteria and higher organisms, and has evolutionary implications of the greatest interest It is clear that important developments in virus genetics are to be expected in the near future

The third lecture is concerned with the ecological approach to virus diseases—what might be called a virocentric point of view How does the virus survive in nature? One of our main methods of defence against virus infections is the production of specific antibody Those viruses whose primary point of attack is in the respiratory tract—e g, influenza and the common cold—have found a weak spot in our defences, where specific antibody is not readily available to meet them, poliomyelitis may come into the same category Infection does not produce a life long immunity to these successful viruses, and it is not a coincidence, therefore, that these diseases are among the most troublesome of the infections of today

Burnet concludes with the suggestion that the academic study of viruses can furnish an approach to many of the fundamental problems of biology Like the biochemist, he feels that living matter is made of fairly uniform bricks, and that information obtained from the careful study of one brick will be found to apply to the other bricks of the building This is a question which only the experimentalist can decide, for theories are but the shadow, and facts the substance, of the scientist's daily life

Dietary Treatment of Laennec's Cirrhosis

The usual methods of controlling ascites in patients with cirrhosis of the liver—repeated paracenteses and the injection of mercurial diuretics—have proved unsatisfactory Drawing off the ascitic fluid depletes the body of protein and aggravates the inanition commonly present in cirrhosis patients The mercurial diuretics, on the other hand, when given alone often do not mobilise water from the peritoneal cavity In combination, the two procedures can be extremely dangerous, for they may precipitate acute depletion of electrolytes and death from the "low salt syndrome" Our ideas about treatment need revision in the light of the newer knowledge of the pathology of ascites in cirrhosis

The classical concept that the ascites results from portal hypertension and hypo albuminæmia is certainly not wholly true and may even be wholly false Raising the low serum albumin levels to normal by infusions of human serum albumin is usually ineffective in these patients, and may sometimes make the ascites worse It has been shown that albumin infused into the blood stream may pass into the patient's swollen peritoneal cavity, where, by osmosis, the albumin will bind the water and salt it has carried from the blood stream This passage of albumin, salt, and water from the circulation to the peritoneal cavity will produce a rapid and distressing increase in the amount of ascitic fluid As for portal hypertension, reducing the pressure in the portal vein to a normal level, by means of portacaval or splenorenal venous shunts, cannot be relied on to relieve the ascites Some patients have had successful shunts made for indications other than ascites—such as hæmorrhage from œsophageal varices—and these patients have later developed ascites although their portal pressure was within normal limits

The primary factor in the genesis of ascites in cirrhosis may be a disturbance in the patient's sodium metabolism In 1948, **Farnsworth**[1] noted that in cirrhotics with ascites or œdema the urinary excretion of sodium was abnormally low, and this observation has since been confirmed many times **Eisenmenger** et al[2] demonstrated that these cases also excrete an abnormally small amount of sodium in their sweat and saliva, though their fæcal excretion is normal At Yale, **Goodyer** and colleagues[3] have demonstrated with salt and-water loading tests and renal clearance estimations that in cirrhotics dietary sodium is retained as a result of increased renal tubular reabsorption These various disturbances in the sodium metabolism are probably associated with overactivity of "11-desoxycorticosterone like" hormones, and both **Eisenmenger** et al[4] and **Kark**[5] have found an abnormally high urinary excretion of cortical hormone in cases of cirrhosis with ascites The cause may be in a failure of the liver to detoxify the mineral retaining adrenal hormones of the blood stream or in excessive secretion by the adrenals. In any case the disturbances in sodium and adrenal metabolism provide, at last, a rational basis for the use of low-sodium and high-protein diets in the management of cirrhotic patients with ascites, whose tissues are notoriously depleted of protoplasm. The results obtained by EISENMENGER et al.,[5] RICKETTS,[6] and KARK,[7] leave no doubt that this regimen is an advance over previous treatments.

In practice, diets high in protein and low in sodium are difficult to plan without using specially prepared protein or amino-acid supplements from which the sodium has been removed by dialysis or otherwise. KARK's paper should be consulted for details of management, diets, recipes, and low sodium food supplements. Before long, however, it should be possible to discard the present rigid sodium restriction and allow the patient fairly normal food, merely following each meal with a dose of the appropriate kation exchange resin, which will remove sodium in exchange for hydrochloric acid during its passage down the bowel.

Medicine and Society

THE measure of the statesman is the gap left by his going. The chairman and the two principal medical speakers at a discussion on social medicine held by the section of epidemiology and State medicine of the Royal Society of Medicine on April 20 referred to the debt of inspiration which they owed to the late Prof. JOHN RYLE. To RYLE social medicine meant the application of medicine to man in society with a view to understanding and alleviating his health problems, and not merely to removing or relieving a present disorder. A wide concept of this kind holds within it various elements for study. An interest in ætiology draws attention to the interactions between man and his environment which influence his mental and physical health. Diagnosis requires measurement of important manifestations of health and disease as they appear in different groups of the community. Rational treatment involves not only the development of social policies to meet needs which have been carefully measured, but also the study of individual and group attitudes to these policies, and measurement of their effects once they have been introduced. The elements are easy to state but less easy to practise. The neat order of the laboratory experiment is not readily paralleled in a complex social environment. Ethical considerations may forbid controlled studies, and emotion and expediency may colour policy, almost unknown to its proponents. Policies adopted to meet a certain set of circumstances are apt to roll on through decades without any careful estimation of what they have achieved or of how they should be modified to meet new needs. The challenge is there and opportunity is not lacking. There is advantage in the present situation where the National Health Service has set us all by the ears. More and more doctors are brought daily to ponder on social policies as they relate to health; and the politicians, now closely concerned with social welfare, need advice in dealing with anticipated health problems. Moreover the new administrative machine, if fully used, can provide invaluable data, not only for assessing its own efficiency, but also for basic studies of our people's well-being.

It was a happy thought that brought together a politician, a general practitioner, and a medical officer of health at the meeting of the Royal Society of Medicine. Mr ARTHUR BLENKINSOP, parliamentary secretary to the Ministry of Health, pointed out the need he feels for guidance through the study of major social changes and the problems they will involve. The politician must, for instance, prepare to deal with an ageing population; and unless he is helped by those aware of the requirements of the elderly he may frame policies from expediency rather than with an eye to the true interests of the people. Twenty years ago, because economic necessity appeared to demand it, early retirement was glibly recommended as a double blessing to solve unemployment and confer leisure on the elderly. Today economic pressure impels us in the opposite direction, and equally glibly we assert that the solution lies in extending the working life of the ageing and so conferring on them the boon of prolonged usefulness. There is a danger that slogans on health may become instruments of casuistry unless we base claims on evidence rather than impression; and this evidence should come from the researches of academic social medicine. If it is true that men benefit by a prolonged working life, then it may be necessary to plan for change of employment rather than retirement. But what is the best age at which to make the change? We may be too late if we wait until the traditional time of retirement. Mr BLENKINSOP set us other questions over which the policy-maker needs guidance: for example, the impact of the stress of contemporary life on mental health, and the hazards to this country from the rapidity of air travel. (As to the speed of air travel, he suggested that enlightened self-interest might force us to develop a more moral attitude to the health of less privileged countries.) He saw danger in the prevalent popular belief that a solution to all social problems may be expected from the wonders of science rather than from pursuing the harder road of social adjustment. Dr G. O. BARBER, too, appealed for help from the exponents of social medicine; but he appealed as a general practitioner, and therefore a field-worker dealing from day to day with problems which are raw material for its studies. As Dr BARBER remarked, the general practitioner holds the data of morbidity research in his hands: he has first impressions of changing stresses on health, but he must look to the professors for guidance on how to ask his questions and order his material, and on how to process this when it has been collected. Dr GREENWOOD WILSON, medical officer of health for Cardiff, described steps he has taken to meet medicosocial needs as a result of suggestions from Professor RYLE. In Cardiff they experimented first with a service of aftercare for diabetic patients. This is provided by specialist health visitors who bridge the gap between hospital and home by maintaining contact with both; and that this experiment has succeeded is suggested by the falling proportion of cases readmitted in coma. Aftercare services have been developed for peptic ulcer, pædiatric, and asthma cases; and plans are under way for a similar service in mental health.

virus multiplies. Recent work on bacterial virus genetics has introduced the disciplines of mathematics into what was once considered a biological field. But the application of similar techniques to animal virus genetics meets with many difficulties. It is comparatively simple nowadays to study the behaviour of a single bacterium infected with a single bacteriophage particle, but it is not yet possible to examine isolated animal cells in this way. This has not deterred BURNET from tackling the problems of virus genetics, and he summarises the results of recent investigations for us. Details of the work have lately been published.[4] Of great interest is the demonstration of combination of characters of two similar viruses—a sort of hybridisation. Two strains of influenza virus were injected together into mice intracerebrally—e.g., strain NWS which has neurotropic properties and MEL which is non-neurotropic. Under certain conditions it was possible to isolate virus with the neurotropic properties of NWS and the serological characters of MEL. Control experiments failed to show that MEL produced neurotropic variants spontaneously. One possible explanation is that the phenomenon is analogous to the transformation of serological types of pneumococci. Recently it has been shown that a desoxyribonucleic acid fraction, isolated from type 3 pneumococci, is capable of conferring type 3 specificity on a pneumococcus of another type. The new hereditary characters are then maintained in the absence of further added desoxyribonucleic acid. A second possibility which BURNET favours, is the hypothesis advanced in order to explain recombination of virus characters in bacteriophages. It is suggested that the influenza virus particle, on entering the infected cell, breaks up into a number of discrete genetic units, that these replicate independently, and that towards the end of the period of multiplication they recombine to form complete virus particles. Such a hypothesis proposes a basically different method of multiplication of viruses from that of bacteria and higher organisms, and has evolutionary implications of the greatest interest. It is clear that important developments in virus genetics are to be expected in the near future.

The third lecture is concerned with the ecological approach to virus diseases—what might be called a virocentric point of view. How does the virus survive in nature? One of our main methods of defence against virus infections is the production of specific antibody. Those viruses whose primary point of attack is in the respiratory tract—e.g., influenza and the common cold—have found a weak spot in our defences, where specific antibody is not readily available to meet them; poliomyelitis may come into the same category. Infection does not produce a life-long immunity to these successful viruses, and it is not a coincidence, therefore, that these diseases are among the most troublesome of the infections of today.

BURNET concludes with the suggestion that the academic study of viruses can furnish an approach to many of the fundamental problems of biology. Like the biochemist, he feels that living matter is made of fairly uniform bricks, and that information obtained from the careful study of one brick will be found to apply to the other bricks of the building. This is a question which only the experimentalist can decide, for theories are but the shadow, and facts the substance, of the scientist's daily life.

Dietary Treatment of Laennec's Cirrhosis

THE usual methods of controlling ascites in patients with cirrhosis of the liver—repeated paracenteses and the injection of mercurial diuretics—have proved unsatisfactory. Drawing off the ascitic fluid depletes the body of protein and aggravates the inanition commonly present in cirrhosis patients. The mercurial diuretics, on the other hand, when given alone often do not mobilise water from the peritoneal cavity. In combination, the two procedures can be extremely dangerous, for they may precipitate acute depletion of electrolytes and death from the "low-salt syndrome." Our ideas about treatment need revision in the light of the newer knowledge of the pathology of ascites in cirrhosis.

The classical concept that the ascites results from portal hypertension and hypo-albuminæmia is certainly not wholly true and may even be wholly false. Raising the low serum-albumin levels to normal by infusions of human serum albumin is usually ineffective in these patients, and may sometimes make the ascites worse. It has been shown that albumin infused into the blood-stream may pass into the patient's swollen peritoneal cavity, where, by osmosis, the albumin will bind the water and salt it has carried from the blood-stream. This passage of albumin, salt, and water from the circulation to the peritoneal cavity will produce a rapid and distressing increase in the amount of ascitic fluid. As for portal hypertension, reducing the pressure in the portal vein to a normal level, by means of portacaval or splenorenal venous shunts, cannot be relied on to relieve the ascites. Some patients have had successful shunts made for indications other than ascites—such as hæmorrhage from œsophageal varices—and these patients have later developed ascites although their portal pressure was within normal limits.

The primary factor in the genesis of ascites in cirrhosis may be a disturbance in the patient's sodium metabolism. In 1948, FARNSWORTH[1] noted that in cirrhotics with ascites or œdema the urinary excretion of sodium was abnormally low, and this observation has since been confirmed many times. EISENMENGER et al.[2] demonstrated that these cases also excrete an abnormally small amount of sodium in their sweat and saliva, though their fæcal excretion is normal. At Yale, GOODYER and colleagues[3] have demonstrated with salt-and-water loading tests and renal clearance estimations that in cirrhotics dietary sodium is retained as a result of increased renal tubular reabsorption. These various disturbances in the sodium metabolism are probably associated with overactivity of "11-desoxycorticosterone-like" hormones, and both EISENMENGER et al.[4] and KARK[5] have found an abnormally high urinary excretion of cortical hormone in cases of cirrhosis with ascites. The cause may be place for the higher grade child; and when children under 2 years of age are certified as "ineducable" before they have had an opportunity to be educated, it is no wonder that some institutional waiting lists are distressingly long.

Many of those dealing with adult defectives have a static conception of mental deficiency. Social conditions have changed so much in the last 20 years that our standards of what the defective can do and cannot do in society must be radically revised. Social security legislation, National Assistance, the disabled persons register, and the abolition of mass unemployment have all greatly altered the problems with which the defective in the community has to cope. Often patients who have spent many years in an institution can be returned to the community to earn their living under the friendly supervision of welfare workers, and many institutions are arranging for them to do this. The Board of Control have wisely encouraged this development, but some institutions are not yet taking full advantage of the changed situation.

The following charges have been made by the National Council for Civil Liberties and given wide publicity: that wrongful certification and detention exist today; that the legal safeguards, which should protect the rights of the individual, are not, in some cases, being applied; that the type of testing used is not adequate to distinguish between temporary educational backwardness and permanent deficiency; that the law is being applied in a far from humane manner; that the use of patient labour creates a vested interest, so that many are detained as useful workers and employed at substandard rates of pay; and that the law itself needs complete revision. These allegations should be thoroughly investigated, and evidence taken from both sides. Misconceptions can then be corrected, and if changes are needed they can be made boldly, with the coöperation of the whole service.

FLUORESCENCE IN GYNÆCOLOGY

THE changes occurring in the vulval skin in health and disease are far from being fully understood, and some useful information may emerge from the studies of Benson and his colleagues[1] in San Francisco or from developments of their technique. This method is based on fluorescence—the property of converting ultraviolet or other radiations with wave-lengths shorter than the blue violet of the visible spectrum into visible light, the advertising potentialities of which are being rapidly explored in England though the fluorescent materials for the poster paints now enlivening the London hoardings are, we understand, all imported from the U.S.A. In medicine fluorescence is no new tool. For many years dermatologists have examined possible cases of ringworm of the scalp under light from a mercury-vapour lamp filtered through Wood's glass, which contains oxide of nickel and transmits very little light outside the ultraviolet range (3600–3300 Å). Healthy hair and skin fluoresce very slightly under this irradiation—looking in the darkroom as if they had been lightly dusted with flour—but the finger nails glow more brightly, and hairs infected with the small spored ringworm give off a brilliant green light for as long as the ultraviolet lamp is turned on them. (If they continued to glow after it was switched off they would be called phosphorescent.)

The vulva is viewed by ultraviolet light that has passed through a complex system of filters. The fluorescent colours seen range from yellow before puberty, through green, to the light-purple of the reproductive period and the deep purple of advanced pregnancy, which soon fades after delivery or if pregnancy is previously terminated. At the menopause the vulva fittingly turns an autumnal brown. These appearances seem to reflect the activity or otherwise of the ovarian hormones. In bleeding states the vulva fluoresces bright red or orange, through the action of porphyrins formed from the decomposition of hæmoglobin which the day's ablutions have not removed. A similar fluorescence due to porphyrins is observed on the tongue[2] in healthy young people and tends to disappear in pernicious anæmia, sprue, vitamin-B deficiencies, and old age; the porphyrins are formed by bacteria and disappear with local applications of antibiotics.

The remarkable colour-changes on the vulva have yet to be explained. It would be interesting to know whether they show any correlation with variations in vascularity demonstrable by infra-red photography, which have been studied in the case of the breasts in pregnancy.[3] Fluorescence of the vulva is unlikely to rival the existing tests for pregnancy, either in accuracy or in consideration for the patient's feelings; and as an indication of missed abortion or intra-uterine fœtal death it is not likely to be taken very seriously. But there is a group of conditions in which the results would be worth studying—those atrophies of the vulva, loosely termed chronic atrophic leukoplakic vulvitis, leukoplakic kraurosis, and the like, whose ætiology, pathology, and hormonic underlay, if any, are still undecided.

HERPANGINA

LESIONS on the mucosa of the mouth and throat are common in many infectious diseases; but, apart from glandular fever and the primary stomatitis of herpes simplex, we know little about the viruses causing sore throat. In 1920 Zahorsky described several cases of an illness that did not fit the pattern of any of the usual bacterial infections, and four years later[4] he suggested that it should be called "herpangina." The name is confusing, for it seems pretty certain that the condition has nothing to do with either herpes simplex or zoster. Similar outbreaks were later described by Levine et al.[5] and Breese,[6] who thought they might possibly be of herpetic origin. Lately Huebner et al.[7] have gone far to establish herpangina as a separate and specific infection, commonly seen in the neighbourhood of Washington, D.C. Last summer the five-year-old daughter of a doctor was taken suddenly ill with fever, headache, and abdominal pain, and when she complained of sore throat her father saw many small ulcers on the anterior pillar of her fauces. Two days later the child was well again; but in the next fortnight 5 of her playmates developed a similar illness, with small punched-out ulcers, having a greyish base and surrounded by a reddened areola, on the fauces, soft or hard palate, and occasionally the tongue. The lesions were not painful and there was no œdema, though one child's ulcers were over 5 mm. in diameter, and persisted for a week. All the children were afebrile within three days. No growth was obtained from the throat swabs taken in 4 of the cases; and if there had not been an epidemiological team working in the area the small outbreak would have joined the thousands of other unexplained outbreaks in the lumber-room of clinical experience. As it was, the throat swabs were examined for viruses, and from 3 of the patients an organism related to group A Coxsackie virus was recovered; it was also recovered from the fæces of all 6 cases, though it had not been present a month before. The virus was shown to be present in the fæces in large amounts in the acute stage of the illness, in decreasing amounts during convalescence, and not at all a month

The chairman, Dr W. H. BRADLEY, reminded us of an exhortation by Johann Peter Frank over a century and a half ago:

> "Let the Government expel from our province the people's misery, most powerful mother of diseases! Then the wife's fertile womb will produce strong and numerous children. The fields cultivated by sinewy arms will thrive. The diseases will return to the cities that are rotten with debauchery. Joy, virtue, patriotism and the former health of the citizens, secured by labour will be restored."[1]

When this phrase was first uttered, strong words had to be used and little governmental action could be expected. Today the danger lies not in lack of action but in action misdirected from lack of knowledge. The discussion showed that policy-makers and field-workers alike may appreciate this danger. The door is open and help is invited. Now it is for the experts of social medicine to respond.

Annotations

BLOOD COLLECTION BY MACHINERY

ACCUSTOMED though we are to machines that calculate and remember and to the rest of cybernetics, it nevertheless comes as a shock to learn that a machine has been perfected that takes in blood and turns out separated red cells, white cells, gamma globulins, and plasma proteins, all without human handling. Yet such, according to the *New York Times*,[2] is the achievement of Prof. Edwin J. Cohn and his colleagues at Harvard. This team has done notable work in the separation of blood fractions, and what they support must be taken seriously. According to the *New York Times* correspondent, the whole processing takes place in a closed system which operates automatically from the donor's vein to the plastic containers for the various fractions. All tubes, needles, and so on are either made of, or coated with, a non wettable material—presumably silicone or plastic. As soon as possible the blood is passed over an exchange resin that removes the calcium and so obviates troubles from clotting. A heat exchange unit then cools the blood, which passes on through a continuous centrifuge that separates cells and plasma. The separated plasma is first passed over another exchange resin that removes prothrombin, then a trace of zinc glycine is added that causes precipitation of gamma globulins and fibrinogen, and these are removed by further centrifuging. After this there remains a "stable plasma protein solution", the zinc is removed by passage over yet another exchange resin, and the solution is sterilised by "cathode rays" and passed to a final sterile container in which it is frozen and dried. The red and white cells are collected into a "protein salt sugar" solution and are separated from one another by centrifuging at different speeds. The machine is said to produce 4 pints of plasma an hour, and can presumably deal with 6–8 pints of blood an hour. It is described as "portable," presumably meaning movable since it comprises three, if not four, centrifuges and a heat exchange unit among all the other gadgets, and this is probably a small scale pilot model since an output of 4 pints an hour is not very rewarding for all the trouble.

We shall await with interest the full description of this remarkable machine, which might well enable the Minister of Health to dispense with much of the staff of the Blood Transfusion Service. Meanwhile it is important to note the modern techniques employed in it, for they may well have applications elsewhere. An unusual feature is the extensive use of ion exchange resins to remove unwanted substances like calcium and prothrombin, without the addition of chemicals, such as oxalate or barium salts, that would be harmful if they got into the final product; the use of resins obviates elaborate steps for subsequent removal of these chemicals. This technique clearly has important applications in blood coagulation studies, especially as it is possible by suitable methods to elute, say, prothrombin that has been removed by a resin. The days of oxalated blood may well be numbered; but relative costs will, we suspect be a determining factor. Professor Cohn considers that his "stable plasma protein" preparation will replace the usual plasma preparations, and it should keep well. It may be an advantage to have red cells separated; their value for transfusion depends on the composition of the "protein salt sugar" solution in which they are suspended.

A NEW DEAL FOR DEFECTIVES

MENTAL deficiency, that usually placid backwater of psychiatry, has had its mud rudely stirred by a report issued by the National Council for Civil Liberties[1]; the popular press has taken up the cause with the result that the public is disturbed and the medical and nursing professions self righteously indignant. It is natural that those working in the mental deficiency service, which is virtually a law unto itself, should resent strongly the criticisms of a lay body; and probably their first reaction to this report will be to dismiss it as an unjust and exaggerated misrepresentation of the truth. Nevertheless, the National Council for Civil Liberties, however sensational their prose style, have evidently gone into the question seriously; and the cases quoted—which they say are only a representative few out of 200 which have already been brought to their notice—are sufficiently disturbing to indicate that a full inquiry into the present administration of the mental deficiency services would not be amiss. Many professional and other associations and committees have recently discussed bringing the Mental Deficiency Act up to date, and the ferment produced by this report may activate new ideas.

The provisions of the Mental Deficiency Act have continued, with only minor amendments as to definitions, since it was passed in 1913. Nothing corresponding to the Mental Treatment Act, 1930, with its revolutionary concept of the voluntary patient has been incorporated into the Mental Deficiency Act. The nearest approach is in section 3, whereby a patient may be "placed" in a mental deficiency institution by his parent without a magistrate's order; but for some obscure reason he is seen by two justices and recertified in the ordinary way at the end of the first year. Even during the first year the parent cannot withdraw his child without the permission of the Board of Control. The position of the child thus bears no resemblance to the position of the voluntary patient.

Because all adult defectives were once children, it is particularly important that "borderline" defective children should not be certified too early. Our schools for the educationally subnormal have places for only 15,000 pupils, though they are expected to cater for our 28,000 educationally subnormal children. In other words, insufficient educational facilities are being provided for this type of child, and some of them are inevitably reported as ineducable. If their home conditions are bad they may then be certified as mental defectives and ordered to a mental deficiency institution. Under present conditions of overcrowding this may not be the best

SINGLE ROOMS IN HOSPITAL

ESTIMATE OF THE MEDICAL NEED

J W D GOODALL
M D Edin, F R C P E
MEMBER OF TEAM INVESTIGATING FUNCTIONS AND DESIGN OF HOSPITALS (NUFFIELD PROVINCIAL HOSPITALS TRUST AND THE UNIVERSITY OF BRISTOL)

THE proportion of beds to be provided in single rooms within the ward unit has an important bearing on ward design Single rooms may be needed as an amenity, for privileged or paying patients, or on medical grounds This paper is concerned solely with the medical reasons for giving patients special accommodation

Studies of the present practice in hospitals do not give a clear indication of what proportion of beds should be in single rooms, or which patients should have them It is, I think, fair to say that at present the provision of single rooms is inadequate The large open ward, which is still the commonest type in this country, has usually one or two single rooms (or in some cases double rooms) attached to it These rooms are often used for convalescent patients of a different social class who would be ill at ease in a large ward, and it is quite common to find the single rooms occupied by sick members of the medical or nursing staff or their near relatives But this, of course, is by no means always the case, and many of the patients in single rooms are there on purely medical grounds For example, the hyperthyroid patient who is very nervous and sometimes irritable, the infectious patient or the patient suspected of infection, and in maternity hospitals the pre eclamptic

Single rooms are also occupied by "nuisance" cases —e g, patients suffering from lung abscess or gangrene of the lung, patients who shout or use foul language, and unsociable or quarrelsome patients, though these latter categories are rather rare In some instances the dying or seriously ill are removed from large wards to single rooms, but more often they are "screened off" in the open ward at a place convenient to the nursing staff for observation

If the above description of present practice in hospital wards is accepted, it will be evident that the claims of the doctor, the nurse, and the patient are all being considered in rather a haphazard way

Since most hospitals were built great advances have been made in medical knowledge We now know more of the causes of infections, and how to control or cure them Consequently, many more tuberculous patients and more infectious patients who would formerly have been sent to isolation hospitals are being treated in general hospitals, and they usually require single rooms or segregation in small wards In addition we have learnt that there are certain groups of patients who are particularly susceptible to infection—especially infants, patients suffering from burns, and those undergoing plastic operations—and they must be isolated

Thus there are overriding medical reasons for providing single rooms Naturally, in so far as segregation of patients increases the work of the nurses and makes observation of patients more difficult, the medical demands may have to be modified But it is essential to know what they are

CLASSIFYING THE REASONS

I began my investigation by asking a number of clinicians, drawn from all specialties, on what medical grounds they would place their patients in single rooms The reasons given by 24 specialists can be summarised under five headings

(*a*) Infective cases (patients liable to infect others)
(*b*) Infectable cases (patients particularly susceptible to infection)
(*c*) Dying and seriously ill cases
(*d*) Nuisance cases (patients likely to disturb others or be disturbed by others)
(*e*) Cases requiring special attention.

Each specialist was also asked to indicate the proportion of beds which he thought should be provided in the form of single rooms, and to state approximately how long a patient would be required to stay in a single room for each reason. Only a minority attempted such estimates, but a few were very definite Two superintendents of fever hospitals said that *all* infectious patients must have single rooms The specialist in the treatment of burns also required 100% single rooms for his patients, and the pædiatrician asked for single rooms for all babies from birth to two years of age Some surgeons wanted their patients to stay in single rooms for 24–48 hours after operation Other specialists estimated the proportion of single rooms required as between 2 and 20%

In order to obtain more precise information on this point I drew up a schedule of conditions warranting single room accommodation, based on the replies from the 24 specialists Each qualification for a single room was given a number, so that when records came to be made a number could be entered for each patient who qualified The 31 conditions fall into the five categories shown above, but it became apparent that patients requiring separate accommodation can also be divided into two main groups (1) those who have to be kept under close observation, and (2) those who require to be separated but who do not necessarily need constant supervision by the nursing staff Examples of the former, which I shall call type A, are dying or seriously ill patients, and cardiac patients needing peace and quiet, examples of the latter (type B) are patients suspected of infection and patients who are smelly or socially unpleasant The division is important from the ward planning point of view, since type A single rooms must be situated for easy observation, and therefore near the centre of the ward, whereas type B single rooms can if necessary be placed at the periphery of the ward

The schedule was as follows

	All dying cases
A	Dying cases
	Infective cases
B	Exanthemata chickenpox, &c
B	Tuberculosis all open cases all meningitis cases all cases receiving special treatment.
B	Venereal disease in infectious stage
B	Ringworm of scalp
B	Mastoid cases
B	Sinus infections.
B	All hare lips cleft palates and major skin losses
B	Suspected cases of infection (likely to infect others)
B	Other infections
	Seriously ill cases
A	Pre-eclamptic and eclamptic cases
A	Bacterial endocarditis
A	Other seriously ill cases
	Infectable cases
B	All burns, for whole period in hospital
A	All infants from birth to age of two years for whole period in hospital
B	Other infectable cases (particularly susceptible to infection)
	Nuisance cases
A	Nervous restless irritable patients—e g cerebral irritation and severe hyperthyroid
B	Smelly or otherwise unpleasant cases—e g lung abscess fistula in perineum offensive discharge
A	Cardiac cases needing peace and quiet
A	Severe vomiting
A	Post traumatic psychosis—e g, foul language indecent behaviour (mainly in association with head injuries and operations)
B	Other nuisance cases
	Cases requiring special attention
A	Eye cases with complications—e g pneumonia
A	Cases receiving special treatment—e g oxygen tent.
A	Postoperative cases (other than very minor operations), and all fenestration cases for 48 hours unless longer period thought necessary

successfully propagated in suckling mice, and in the convalescent sera of 4 of the human cases high levels of neutralising antibody were demonstrated against H_1 but not against other strains of virus

The epidemiologists soon established that doctors in the Washington area had seen many young children in the summer of 1950 with a mild uncomplicated fever and the typical vesicular or ulcerated lesions in the throat These might have been examples of herpetic, aphthous, or Vincent's stomatitis, so fæcal and other specimens were obtained from 31 of the cases and the virus of herpangina was isolated from 26 of them In suckling mice all the strains produced lesions which were indistinguishable from those caused by known strains of group A Coxsackie virus The immunological relationships of these viruses have yet to be worked out, but four H types (H_1–H_4) have already been differentiated by complement fixation and cross immunity tests Two previously known types of Coxsackie virus—group A type 2 and the High Point Texas type—have recently been isolated from more typical cases of herpangina, and this is probably only a beginning In the original epidemiological study the H virus was seldom recovered from people who were not known to have been in recent contact with cases of frank herpangina, and it was rare to find it in people with other illnesses Thus we have yet another disease to add to summer grippe, paralytic and non paralytic poliomyelitis, epidemic myalgia, and other conditions thought to be associated with the Coxsackie viruses In this diagnostic morass it is well to remember that some of the reports are of doubtful value, and that Dalldorf is cautious about the part these viruses play in causation Nevertheless, the experience and critical tests applied by Huebner et al strongly suggest that these viruses are intimately associated with herpangina, and this illness may well turn out to be the chief, if not the only, clinical manifestation of human infection with the A group of Coxsackie viruses

METHÆMOGLOBINÆMIA IN INFANCY

IN infants cyanosis is a common sign, and usually there is no difficulty in discovering its cause in the heart or lungs In the absence of cardiac or pulmonary disease, however, diagnosis is less easy, and the solution may be found by examining the blood for evidence of the abnormal pigments, methæmoglobin and sulphæmoglobin Simple inspection of the blood will reveal the characteristic chocolate colour of methæmoglobinæmia

The causes of methæmoglobinæmia can be grouped under the headings of toxic, hæmolytic, and idiopathic For several years pædiatricians have been intrigued by the toxic causes These are aniline derivatives, the sulphonamides, especially sulphapyridine and sulphanilamide, acetanilide, phenacetin, phenazone, methyl sulphonal and sulphonal, potassium chlorate, and the nitrites The newer sulphonamides do not cause methæmoglobinæmia, and there seems no reason to prescribe any of the other drugs to infants Roe[1] has reported a fatality from administration of bismuth subnitrite There are two main sources of accidental poisoning The first of these to be recognised was the aniline derivatives in ink used to mark napkins[2], and several outbreaks in maternity units have been traced to this cause[3] Prevention is secured by laundering all napkins before use The second source of accidental poisoning was brought to light in 1945 by Comly,[4] who first recognised methæmoglobinæmia in bottle fed babies under two months of age whose drinking water came from wells contaminated by nitrates Since then the con

Canada,[5] and in Belgium[6] Dr Ewing and Dr Mayon White[7] have described the first cases in England, a further case is reported in this issue by Dr Evel Jones Prevention of this well-water cyanosis is difficult but Krueger[8] has described two methods of removing nitrate from water by anion exchange resin Some rare causes of methæmoglobinæmia are mentioned by Dr Oppé in his article on p 1051

The reason why only infants under two months of age should develop methæmoglobinæmia is not clear Cornblath and Hartman[9] suggested that, owing to the gastric hypochlorhydria of infancy, the nitrate nitrite reducing organisms inhabit the upper as well as the lower bowel, and thus the area for reduction of nitrates and absorption of nitrites is greatly increased Lecks,[10] on the other hand, believes that the capacity of fœtal hæmoglobin to reduce methæmoglobin is less than that of adult hæmoglobin The poor excretory power of the infantile kidney, and a possible deficiency in ascorbic acid have also been named as contributory causes. Toxic methæmoglobinæmia can be treated very effectively In experimental methæmoglobinæmia methylene-blue (methylthionine chloride) in a dosage of 1–2 mg per kg body weight intravenously will convert all the methæmoglobin into active hæmoglobin within forty five minutes[11] In man its use was introduced by Williams and Challis[12] and Steele and Spink[13] with equally satisfactory results. This forms the mainstay of treatment, although blood transfusion and oxygen therapy are valuable adjuvants. Ascorbic acid, which also reduces methæmoglobin, acts too slowly to be useful in acute poisoning[14]

Hæmolytic methæmoglobinæmia may be found in phenylhydrazine poisoning and in severe infections. Cyanosis with hæmoglobinuria and jaundice has been noted in outbreaks among neonates, and has been given the title Winckel's disease[15], but this is probably a manifestation of intense septicæmia and not a specific entity Idiopathic methæmoglobinæmia is rare and may exist only in a familial form, but Schwartz and Rector[16] could find no cause for their non familial cases. The familial group is well defined[17] Breakey et al.[18] have shown in two cases that the erythrocytes have an abnormally low capacity to reduce methæmoglobin in the presence of glucose and lactate, and that the activity of diaphorase I (co enzyme I) is deficient, thus proving the long suspected metabolic abnormality in the disease[19] In this condition cyanosis can be controlled by ascorbic acid in large doses or methylene blue by mouth.

The few tragedies due to methæmoglobinæmia in infancy could have been avoided if the diagnosis had been made and the simple treatment more widely known The recognition of "well water methæmoglobinæmia" in England should increase our awareness

Air Vice-Marshal J MACCONNELL KILPATRICK has been appointed director-general of Royal Air Force Medical Services in succession to Air Marshal Sir PHILIP LIVINGSTON, who retires on June 30

SUMMARY

A survey was undertaken to determine what proportion of beds in a ward should reasonably be provided in single rooms in order to satisfy the medical needs of the patient.

After reference to a number of consultants, a list of 31 conditions qualifying patients for accommodation in single rooms was compiled.

This schedule of conditions was used by housemen, in 29 wards of 8 general hospitals, to record each day over a period of a month whether the patients in the ward qualified for single rooms.

An analysis of these records enabled conclusions to be drawn about the most desirable provision of single rooms. For wards of sixteen beds these are

General medical wards	4 single rooms
General surgical wards	3 „ „
Gynæcological wards	3 „ „
Maternity wards	2 or 3 single rooms

For larger wards the proportion of single room beds to total beds would be somewhat less and for smaller wards it would be somewhat greater.

I should like to thank the staff of the 8 hospitals who kept such painstaking records on their daily rounds, and Mr Bailey for his invaluable statistical work on analysing the records.

WINTER ADMISSIONS TO LONDON HOSPITALS

Work of the Emergency Bed Service, 1950-51

As is generally known, in the past winter great difficulty was experienced in London in the admission of acutely ill patients to hospital. These difficulties caused great hardship to patients as well as extra work for their doctors. But it is not easy to turn these generalisations into facts and figures. There are no figures to show the total number of urgent cases requiring admission to the London hospitals, though many of the hospitals keep a note of their own figures. Thus the figures of the Emergency Bed Service (E.B.S.) seem to be the only ones covering greater London as a whole.

The E.B.S. is an auxiliary service intended to help doctors who have made an unsuccessful direct application for the admission of a patient to the hospital of their choice. What proportion of the acute cases in London are admitted through such direct applications by their doctors could only be discovered by putting a lot of extra work on hospital officials. Random checks have shown that some hospitals admit three or four acute cases direct from doctors to every one admitted through the E.B.S., in others the proportion is about equal, and on the average the ratio of direct to E.B.S. seems to be about 2 : 1. But these proportions apply to total admissions, and it must be remembered that the doctor who cannot get his patient admitted direct can apply to the E.B.S., who may be more fortunate; whereas if the E.B.S. fails to find a bed for a patient the failure is usually final. Thus, though only about a third of all the admissions are arranged through the E.B.S., the service's failures represent a much larger proportion of the total—indeed, if all London doctors make a rule of trying the E.B.S. before resigning themselves to keeping the patient at home then the E.B.S. failures will be the total failures in London. Broadly speaking, then, the E.B.S. experience will give a reasonably representative picture of the position in London.

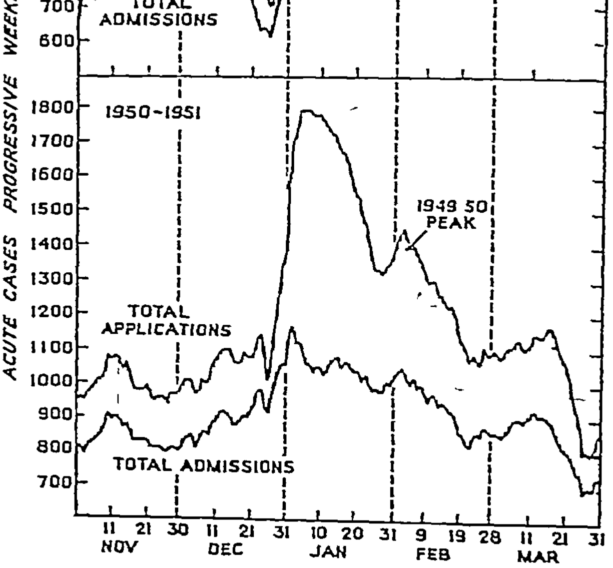
THE WINTER'S WORK

The work of the E.B.S. followed normal lines until Dec. 9, 1950, when, presumably owing to the influenza epidemic, it began to increase rapidly, instead of slackening, as is usual, before Christmas. For the first time in the 13 years since the service started, Christmas Day, 1950, was a busy day, 106 applications being received for the admission of acute cases compared with 68 on Christmas Day, 1949. Thereafter the curve of applications rose steadily, as it always does after Christmas; and on Jan. 1, 1951, the total reached its peak figure of 293—the highest number yet recorded on one day. This exacerbation lasted for about 10 days, after which the demand began to fall steadily; even so, January's applications were 35% higher than the total for January, 1950.

The accompanying chart shows that the admissions kept up fairly well with the applications until Christmas, but thereafter the admissions rapidly fell behind; for the whole of January the E.B.S. found a bed in only two thirds of the cases applying for admission. In other words, one applicant out of every three could not get into hospital. For February and March the proportions of successful applications were 75.7% and 80.5%, and by the end of March the E.B.S. was once again working pretty well normally.

What do these figures mean in actual cases? At the worst time the failures amounted to 100 a day. In January applications for admission were received for 7064 acute medical and surgical cases, of which 4632 were admitted and 2432 could not be placed. Among the patients for whom beds could not be found were 247 whose applications were withdrawn, and these should not be counted among the failures. Without them the month's daily average of failures was 70.5.

If we assume that an application is received by the E.B.S. for 1 in every 3 urgent cases and that the remainder are all admitted direct—for otherwise the doctors will surely try the E.B.S.—then the total number of patients applying for admission to the London hospitals in January was three times the total E.B.S. applications, or about 21,200; all except the E.B.S. failures were admitted, so the failure rate for London as a whole can be estimated as 11.6%. The E.B.S. served an area containing 200 hospitals, not counting fever hospitals



A Epilepsy and all cases of ' fits
A Shock cases having drip treatment
A Cases in labour a long time with ruptured membranes
A Failed forceps
A Cases requiring constant supervision
A Other cases requiring special attention

THE SURVEY

In the main survey (undertaken after a preliminary pilot survey) residents in 8 hospitals cooperated by recording on their daily rounds those of their patients who qualified for a single room according to the schedule I had prepared Returns were made by residents in 29 wards over a period of at least a month There were 10 surgical wards, 10 medical, 4 gynæcological, 3 maternity, and 1 each of children, and of ear, nose, and throat patients The total number of beds covered was 1010

The records showed that, of the 31 possible reasons for wishing to place patients in single rooms, some were given much more often than others For example, patients often qualified for single rooms because their condition was smelly, infectious, or otherwise unpleasant Comparatively few needed separate accommodation because they had sinus infections, eclampsia, or eye complications This was to be expected, because most of the records were made in general hospitals and not in hospitals or wards for special diseases

It was found that the demand for separate accommodation fluctuated widely from day to day in all the wards, but except for two surgical wards, both in the same hospital, the types of demand for single rooms appeared to be roughly comparable within a given specialty Because of these considerable fluctuations in daily demand, a simple estimate of the *average* requirement fails to give a correct estimate of the number of rooms that should be provided The data therefore needed statistical analysis, and this was undertaken by Mr N T J Bailey, statistician to the Department of Medicine, University of Cambridge, with the results set out below

Because of the daily fluctuations in demand it is important to distinguish between how much of the demand can be met (efficiency of provision), and to what extent the single rooms available are occupied for their proper purpose (efficiency of utilisation) The former efficiency can be made very high only at the expense of the latter, and vice versa, for if enough single rooms are provided to cope with all requirements on "peak" days, many of them will not be used for their proper purposes on other days Mr Bailey found it possible to construct a simple mathematical model of the situation, from which the two efficiencies could be calculated in terms of ward size and the average chance of a patient selected at random requiring separate accommodation (approximately constant for a given specialty), for different numbers of single rooms provided The statistical theory employed takes account of the fact that data may be drawn from wards of different sizes, and it can be used to calculate tables, similar to those below, for wards of any size Results for 16 bed medical and surgical wards are shown in tables I and II From such tables the two efficiencies can be read off for different numbers of single rooms provided If a proper balance is to be struck between medical requirements and the necessity for economy of space—and finance—the hospital planners will choose that number of single rooms which gives the highest value for the efficiency of provision, consistent with a reasonably high value for the efficiency of utilisation

TABLE I—MEDICAL WARD, 16 BEDS BASED ON DATA FROM 10 WARDS

No of single rooms	Both types of single room		Type A rooms only	
	Efficiency of provision (%)	Efficiency of utilisation (%)	Efficiency of provision (%)	Efficiency of utilisation (%)
2	47	97	65	86
3	67	92	84	74
4	82	84	94	62
5	92	75	98	52
6	97	66		

Medical Ward

Table I shows that in a sixteen-bed medical ward four single rooms, three of type A and one of type B, should be able to deal with 84% of the type A requirement and 82% of the total requirement for single rooms These four single rooms would be appropriately occupied 84% of the whole time The three type A rooms would be used for type A cases only 74% of the time, but for some of the rest of the time they would obviously be employed to cope with excesses of type B patients

Surgical Wards

The data for 2 of the surgical wards (both in the same hospital) were so widely different from those from the other 8 that after careful consideration they were rejected as anomalous Table II is accordingly based on the data for the 8 only It shows that in a sixteen bed surgical ward, three single rooms, two suitable for type-A and one suitable for type B patients, should be able to deal with 84% of total requirements and with 76% of type A requirements This scale of provision, though satisfactory from the medical standpoint, will be somewhat wasteful of ward space since the rooms will be appropriately occupied only 74% of the time Similarly the two type A rooms would be used for type A patients only 73% of the time, though for the rest of the time they could, of course, be used for excesses of type B patients or for other purposes

TABLE II—SURGICAL WARD, 16 BEDS BASED ON DATA FROM 8 WARDS

No of single rooms	Both types of single room		Type A rooms only	
	Efficiency of provision (%)	Efficiency of utilisation (%)	Efficiency of provision (%)	Efficiency of utilisation (%)
1	36	95	45	87
2	65	86	76	73
3	84	74	92	59
4	94	62	98	47
5	98	52		

Gynæcological Wards

Data were available from 4 wards and suggest a total of three single rooms out of sixteen, two for type A and one for type B patients This would satisfy 75% of the total demand and use 86% of the accommodation provided At the same time 80% of type A demand would be satisfied with a utilisation efficiency of 67% (Though this could be increased to 83% by having only one type A room, this would satisfy less than half the demand)

Maternity Wards

There were data from only 2 wards Two single rooms out of sixteen are probably the best provision, satisfying 71% of the demand and using 79% of the accommodation Some might prefer to use three rooms, satisfying 88% of the demand but using only 66% of the accommodation In either case, if we are to satisfy more than 66% of the type A demand two rooms would have to be of type A

Children's Wards

For this category data are available on only 1 ward and it would be unsafe to give more than a very tentative indication The total requirement is perhaps seven single rooms out of sixteen, of which two would be for type-A patients consistently outwits mere human opponents in an arithmetical game called Nim. Genetics is generously represented with large-scale translucent models of a unicellular organism in which movements of the chromosomes can be followed, and the ground is prepared for the introduction of the concept of mutations and their evolutionary significance. This theme is developed using drosophila as an illustration, but a much more striking example of a genetic variant is provided by a pair of waltzing mice who circle madly round their little arena while the normal mice next door doze peacefully. Genetics leads naturally to embryology, which lends itself well to explanation by models. In other corners are to be found exhibits to demonstrate the rôle of enzymes in the life cycle, the mechanism of the human and insect eye, and the appearance of common bacteria and viruses.

The descriptions of each exhibit are so worded as to be comprehensible to an uninitiated viewer, but simplification is surely overdone by such phrases as "The earthworm is simply a sac full of fluid." The display in general is influenced by the artists' impression of science rather than a scientist's impression of his own subject. Nevertheless this slightly unreal approach and several inadequacies in labelling and description do not seriously detract from the value of an exhibition which is so thoroughly in step with the times and which explains in simple ways such fundamental concepts.

Public Health

POTENCY OF VACCINE LYMPH

A. ANDERSON

M.D. Aberd., D.P.H., D.I.H.

DEPUTY CHIEF MEDICAL OFFICER, ANGLO-IRANIAN OIL COMPANY LTD, ABADAN, SOUTH PERSIA

THE calf lymph used in vaccination against smallpox quickly loses its potency under normal storage conditions, and in the tropics this loss is even quicker. The danger of using impotent vaccine is not only that the vaccination will not "take" but that it may produce an allergic papule indistinguishable from an immediate reaction.

At Abadan, a town of some 200,000 inhabitants near the head of the Persian gulf, about 30–60 cases of smallpox are recorded in non-epidemic years, and during the past nine years there have been two epidemic outbreaks—one in 1942–43 and the other in 1948. Despite every effort, a high level of immunisation cannot be maintained in the population because of the migration which goes on throughout most of the year. Thus when a major outbreak starts it is of the first importance to use vaccine of assured potency, and in the 1948 outbreak the method described below proved particularly effective.

The vaccine was sent by air from Great Britain, packed in ice in vacuum flasks. On arrival in Abadan it was taken immediately to a refrigeration room, where it was kept at a temperature of 14°F. (In winter the atmospheric temperature at Abadan may rise to about 120°F in the sun and 70°F in the shade.)

Small circular tins, about 10 in. in diameter and 5 in. deep were manufactured. In the centre of each tin was a circular compartment of the same depth with a diameter of about 1½ in. At the start of the working day the outer compartment was filled with a mixture of ice and salt, and into the central compartment were placed enough tubes of lymph for the number that the vaccinator could deal with in a single day. Strict instructions were issued that any vaccine which remained unused at the end of the day was to be destroyed, on no account was it to be used even on the following day.

With this technique some 85–90% of vaccinations "took." Judged by comparison with experience in the epidemic of 1942–43 when this method was not employed, it affords an improved hope of effective vaccination in tropical and subtropical countries.

The need for such a precaution is suggested by the following instances.

A driller, middle-aged, tough, and oft-vaccinated, said that he never "took", but the cold stored vaccine, with which he was vaccinated as a routine after his three-yearly medical examination, produced an accelerated reaction which was as nearly primary as could be desired.

About the time of the 1942–43 outbreak, the American army set up a 500-bed hospital about twelve miles from Abadan and we formed a close liaison. One day we received an S.O.S., and found half of the hospital's professional staff suffering from modified smallpox. This unit had arrived a fortnight before, and coming from a northern State of the U.S.A. where smallpox is non existent, its members had gathered round the first case of smallpox in the hospital. Anamnestic evidence made it clear that the *vaccinations of this unit before it embarked had not been successful*, although fortunately all its members had been successfully vaccinated in childhood. A seaman patient in the hospital and a paymaster, the former unvaccinated and the latter with an unsatisfactory vaccination history, both died of hæmorrhagic smallpox about the same time.

We know that repeated vaccination with *potent* vaccine is the means of preventing smallpox. Vaccination should be given the same publicity as the antidiphtheria campaign, and it should be pursued with vigour from infancy throughout the school years, otherwise there may soon exist in Great Britain a population continuously susceptible to outbreaks of a loathsome, disfiguring, and deadly disease, which can be prevented.

I wish to thank Dr S. D. McClean, chief medical officer to the Anglo Iranian Oil Company Ltd, for permission to publish this report.

Smallpox

Modified smallpox was diagnosed in a student from Calcutta who was disembarked at Marseilles from s.s. *Ranchi* on April 30. The *Ranchi* docked on May 8 in the Port of London. Warning letters are being sent to the medical officers of health for districts to which contacts are proceeding.

In an outbreak of smallpox at Tilburg, Holland, there had been altogether 29 cases up to the beginning of this week. There had also been 1 case at Utrecht and 1 case at Geldrop, which were contacts with the cases at Tilburg.

Statistics for Northern Ireland

In Northern Ireland during the year 1950 the *infant and maternal mortality rates and the tuberculosis death-rate were the lowest ever recorded.* The Registrar-General for Northern Ireland announces that the infant-mortality rate was 40 per 1000 live births, and the maternal mortality rate 1.2 per 1000 live births, compared with 45 and 1.4 in 1949. The death-rate from tuberculosis was 48 per 100,000 population.

* Not including late returns. † Not louse-borne. Imported case.

or highly specialised ones A daily average of 70 5 unsuccessful applications for admission suggests that enough extra beds to accommodate all the acute cases could be provided without laying an impossible burden on the hospitals

This may read like an attempt to explain away the winter's anxieties, but it was in fact a time of serious crisis, and the regional boards, whose agent the E B S is, took all the steps open to them to overcome it

THE FUTURE

Plans now being made on the basis of the winter's experience should go far to prevent the recurrence of such an emergency and enable the hospitals and their auxiliaries to deal with any unduly large number of applications for admission

It is clearly impracticable always to keep enough empty beds fully staffed and ready for the acute cases to meet major crises which only arise occasionally Even if it was possible, this would be an unjustifiable waste of personnel and material In an emergency, hospitals can usually increase their accommodation for acute cases by admitting fewer patients from their waiting lists and by other means

This winter, however, the position was complicated by the large number of nurses and other members of the hospitals' staffs who were incapacitated by influenza In future epidemics the same complication will almost certainly recur, and this must be taken into consideration when devising plans for the future

The scheme now being prepared is an adaptation of the air raid warning system of the late war The warning system will come into operation automatically when the pressure on the E B S mounts above a prearranged level When applications for admission reach the critical figure, a warning will be despatched to all the hospitals in the London area, this will be the signal for them to take whatever steps they consider necessary to clear beds for acute cases The scheme is intended to bring the full power of the hospitals to bear in a crisis, but there will be a corresponding system of all clear signals to ensure that the hospitals are not called on to continue their supreme effort when the immediate crisis is over

---

THE FESTIVAL EXHIBITIONS

MEDICAL SCIENCE DISPLAYED

On May 3, the Festival of Britain was inaugurated by H M The King and on the following day the South Bank Exhibition opened its doors At last therefore there is an opportunity to judge this much criticised venture on its own merits, unclouded by controversy as to whether it ought ever to have been

THE SOUTH BANK

The first and most remarkable impression is the sense of space on this very restricted site Hemmed in by the River and York Road, by County Hall and Waterloo Bridge, the designers have achieved an astonishing amount of elbow room, and the great central concourse, with its flower beds, fountains, and trees is most unexpected The river terrace, on the inner bend of the river, commands the whole sweep from Westminster to St Paul's and is certainly a magnificent permanent accession to the beauties of London—a new "lung" of inestimable value from which the gay busy life of the river can be watched against a varied and fascinating skyline The architecture of the exhibition buildings is very modern, and of its kind excellent, with bold sweeping lines, clear bright colours, and skilful use of space Those who like such things will enjoy it, those who do not will hate it There are enough "modernistic" statues and frescoes to provide controversy for many a dinner table

The twenty pavilions set out to illustrate the contribution of Britain in many fields of science, engineering, and industry The way of life of the British people, their character and homes, their sport, recreations, and scenery, are all covered, and it is notable that the Official Guide lays much stress on the importance of all these to health Health however, has a pavilion to itself, under Waterloo Bridge, where the contributions of Britain to medical science and art are displayed and where the value of these contributions to the community and the individual are illustrated

At the entrance to the Health Pavilion is a section on "how the body works," illustrated by admirable working models of the circulation and respiration and of reflex action, and a less convincing one of the alimentary tract This leads on to nutrition and thus to "the preservation of health," the latter including public health, water, sewage, immunisation, and so on The contributions of medicine and surgery are next dealt with surgical instruments are well displayed and biological standards are also shown Blood transfusion is excellently handled, and then comes a section on anæsthesia A large wall painting of Florence Nightingale at Scutari, effective but somewhat imaginative, introduces a number of screens illustrating various aspects of nursing, and finally there is a remarkable section on plastic surgery This is likely to cause more controversy than all the rest of the pavilion put together Two excellent models demonstrating how burns and scalds can occur in children and old people lead on to a series of photographs, some in colour, illustrating the treatment of such burns—as well as the effects of inadequate treatment Punches are not pulled here, and it is questionable how far the propaganda effect in the preventing of burns will outweigh the protests of the squeamish Of the quality and sincerity of this section there can be no question—the photographs are brilliant—and it may well do much good

The Royal Festival Hall is perhaps the most exciting thing on the South Bank At the moment it looks rather incongruous—a huge solid mass among the flimsy exhibition structures—and it is too early to judge how its outside will look when completed and surrounded by parks and river walks But of its triumphant interior there can be only one opinion London once more has a concert hall where music can be properly heard in a comfort never previously experienced, and the planning of the promenades, restaurants, and foyers is spacious and dignified, giving really magnificent views of the river If nothing else had come out of the Festival of Britain this would have been worth while

SOUTH KENSINGTON

At the Festival Exhibition of Science, to be seen at the Science Museum, South Kensington, there is a sprinkling of medical demonstrations among the predominant ones illustrating the atomic age Indeed from the very entrance through a tortuous darkened tunnel, perhaps more suggestive of an approaching fun fair than a scientific exhibition, one is confronted with larger and larger scale models of the ultimate structure of graphite On emerging from the darkness the main exhibition hall is a dazzle of light coming from stereotyped structural formulæ constructed of electric bulbs, artificial lightning, and glowing cathode ray tubes This atomic approach merges easily with medicine in the description of the use of isotopes to measure the rate of replacement of plasma proteins and red cells and the use of isotopically labelled B_{12} for the study of its metabolism

Models illustrate the use of X ray diffraction in crystallography, and an imposing electronic brain consistently outwits mere human opponents in an arithmetical game called Nim. Genetics is generously represented with large scale translucent models of a unicellular organism in which movements of the chromosomes can be followed, and the ground is prepared for the introduction of the concept of mutations and their evolutionary significance. This theme is developed using drosophila as an illustration, but a much more striking example of a genetic variant is provided by a pair of waltzing mice who circle madly round their little arena while the normal mice next door doze peacefully. Genetics leads naturally to embryology, which lends itself well to explanation by models. In other corners are to be found exhibits to demonstrate the rôle of enzymes in the life cycle, the mechanism of the human and insect eye, and the appearance of common bacteria and viruses.

The descriptions of each exhibit are so worded as to be comprehensible to an uninitiated viewer, but simplification is surely overdone by such phrases as "The earthworm is simply a sac full of fluid." The display in general is influenced by the artists' impression of science rather than a scientist's impression of his own subject. Nevertheless this slightly unreal approach and several inadequacies in labelling and description do not seriously detract from the value of an exhibition which is so thoroughly in step with the times and which explains in simple ways such fundamental concepts.

Public Health

POTENCY OF VACCINE LYMPH

A. ANDERSON

M.D. Aberd., D.P.H., D.I.H.

DEPUTY CHIEF MEDICAL OFFICER, ANGLO-IRANIAN OIL COMPANY LTD, ABADAN, SOUTH PERSIA

THE calf lymph used in vaccination against smallpox quickly loses its potency under normal storage conditions, and in the tropics this loss is even quicker. The danger of using impotent vaccine is not only that the vaccination will not "take" but that it may produce an allergic papule indistinguishable from an immediate reaction.

At Abadan, a town of some 200 000 inhabitants near the head of the Persian gulf, about 30–60 cases of smallpox are recorded in non-epidemic years, and during the past nine years there have been two epidemic outbreaks—one in 1942–43 and the other in 1948. Despite every effort, a high level of immunisation cannot be maintained in the population because of the migration which goes on throughout most of the year. Thus when a major outbreak starts it is of the first importance to use vaccine of assured potency, and in the 1948 outbreak the method described below proved particularly effective.

The vaccine was sent by air from Great Britain, packed in ice in vacuum flasks. On arrival in Abadan it was taken immediately to a refrigeration room, where it was kept at a temperature of 14°F. (In winter the atmospheric temperature at Abadan may rise to about 120°F in the sun and 70°F in the shade.)

Small circular tins, about 10 in. in diameter and 5 in. deep were manufactured. In the centre of each tin was a circular compartment of the same depth with a diameter of about $1\frac{1}{2}$ in. At the start of the working day the outer compartment was filled with a mixture of ice and salt, and into the central compartment were placed enough tubes of lymph for the number that the vaccinator could deal with in a single day. Strict instructions were issued that any vaccine which remained unused at the end of the day was to be destroyed, on no account was it to be used even on the following day.

With this technique some 85–90% of vaccinations "took." Judged by comparison with experience in the epidemic of 1942–43, when this method was not employed, it affords an improved hope of effective vaccination in tropical and subtropical countries.

The need for such a precaution is suggested by the following instances.

A driller, middle aged, tough, and oft-vaccinated, said that he never "took", but the cold stored vaccine, with which he was vaccinated as a routine after his three-yearly medical examination, produced an accelerated reaction which was as nearly primary as could be desired.

About the time of the 1942–43 outbreak, the American army set up a 500-bed hospital about twelve miles from Abadan, and we formed a close liaison. One day we received an S.O.S., and found half of the hospital's professional staff suffering from modified smallpox. This unit had arrived a fortnight before, and coming from a northern State of the U.S.A. where smallpox is non-existent, its members had gathered round the first case of smallpox in the hospital. Anamnestic evidence made it clear that the vaccinations of this unit before it embarked had not been successful although fortunately all its members had been successfully vaccinated in childhood. A seaman patient in the hospital and a paymaster, the former unvaccinated and the latter with an unsatisfactory vaccination history, both died of hæmorrhagic smallpox about the same time.

We know that repeated vaccination with *potent* vaccine is the means of preventing smallpox. Vaccination should be given the same publicity as the anti-diphtheria campaign, and it should be pursued with vigour from infancy throughout the school years, otherwise there may soon exist in Great Britain a population continuously susceptible to outbreaks of a loathsome, disfiguring, and deadly disease, which can be prevented.

I wish to thank Dr. S. D. McClean, chief medical officer to the Anglo-Iranian Oil Company Ltd., for permission to publish this report.

Smallpox

Modified smallpox was diagnosed in a student from Calcutta who was disembarked at Marseilles from s.s. *Ranchi* on April 30. The *Ranchi* docked on May 8 in the Port of London. Warning letters are being sent to the medical officers of health for districts to which contacts are proceeding.

In an outbreak of smallpox at Tilburg, Holland, there had been altogether 29 cases up to the beginning of this week. There had also been 1 case at Utrecht and 1 case at Geldrop, which were contacts with the cases at Tilburg.

Statistics for Northern Ireland

In Northern Ireland during the year 1950 the infant and maternal mortality rates and the tuberculosis death-rate were the lowest ever recorded. The Registrar-General for Northern Ireland announces that the infant-mortality rate was 40 per 1000 live births, and the maternal mortality rate 1.2 per 1000 live births, compared with 45 and 1.4 in 1949. The death rate from tuberculosis was 48 per 100,000 population.

In England Now

A Running Commentary by Peripatetic Correspondents

THE great physician patted my shoulder "My dear," he said kindly, "you are suffering from Housewife's Fatigue" Biting down a retort of "You're telling me!" or "Aren't we all!" and reminding myself once again that I would not be charged his usual fee, I thanked him prettily The examination had been very thorough He advised rest and massage I fancied he was going to suggest a folding of the hands in the South of France when he remembered my husband is a G P, so he offered me tea and biscuits instead

Massage gives one a lot of time to think, and I have occupied my sessions in wondering what research into this fatigue business would reveal The incidence in age-groups has been worked out at a local hospital, but I have seen no mention of the types of housewives afflicted or of how to recognise the onset What is the precipitating factor? Doctor's wives will, of course, realise something is wrong if they hear the telephone at dead of night when there has been no call or find themselves starting at bicycle-bells in the street, if even the most innocent of one's husband's victims in the waiting-room is seen to be a drug addict or potential suicide and the simplest message becomes fraught with shocking implications But what are the corresponding symptoms in other people's wives? Does the wife of a racehorse owner stand transfixed on meeting the milkman's horse and grip the railings with her jewelled fingers, yelling "Come on, Stêve!" until she is led away by an understanding policeman? Does the engine driver's wife mistake an owl's hoot for the 9 15 drawing in and hastily prepare her good man's evening meal? I recommend this fascinating field of research to my husband's colleagues

Meanwhile, perhaps some medical M P would put this question to the Minister of Health

> "Is the Minister aware that the incidence of fatigue is increasing among housewives in Great Britain, and that unless something is done vast numbers of new housewives will have to be imported from Argentina at great national expense?"

This is Festival Year Wouldn't it be wonderful if for once we were spared the usual stilted reply and got this honest British retort

> "The Minister is well aware of the situation He couldn't care less"

I am afraid the Argentine housewife idea will appeal to husbands I can imagine her murmuring "Mañana" ever so sweetly into the phone

Anyone requiring further information should write to me I ought to know something about the subject, for I've got the disease Excuse me, there's another drug addict hammering on the door

* * *

When patients in sanatoria or mental hospitals take up their paint brushes and slap down their opinions of their surroundings or of life the results are exhilarating, and shows of pictures from such beginners lift the spirits in a remarkable way, but at the Royal Academy I found my spirits drooping Our professional artists paint much better, of course, but they also seem to have much less to say, and they say it so respectably no fulminations of rage against mother, no searching criticism of the hospital staff, no bursts of brilliant light or sulphurous darkness, matching a mood, no unlikely horses in the clouds or faces in the flowers, no meticulous windings of a thread, no birds or beasts fashioned of tiny coloured particles as though a coral insect had set out to paint a picture Just nice ordinary paintings which slide the onlooker back into his rut and turn on the rain A spark of rebellion comes from Richard Eurich in *A Judgment*, where the font end of a church is mysteriously full of tumbling instruments of music, flung down in such a headlong rush from the tower that the crimson curtains billow in the draught Otherwise I should put the psychological state of the exhibitors at about two glasses below par, except for one or two really bad depressions in purples, blues, and black, and an occasional euphoria in the reds *Les Jardins du Luxembourg*, by Derek Clarke, however, seemed jolly in its own right, and I would have gone off with James Fitton's *Woodland Path*, if that could have been arranged without unpleasantness Of professional interest were Prof T F Flower's wife and family, charmingly done by Dr Henry Lamb, and Dr Winifred Doherty had had the luck to be painted by Stanley Spencer Sir Alexander Fleming, in John Wheatley's clever drawing in chinese white, peers faintly out of green paper, looking like Beethoven—or a banshee

* * *

I can now disclose the menu and arrangements for the annual dinner dance shortly to be held by the Royal Society of Medicine (Section of General Practice) Having taken their seats at table members will read their morning papers for the five minutes needed for the preparation of the first course, an *Œuf Poché Interrompu*, "washed down" (as gourmets say) with *L'Eau Froide à Boire d'un Trait* When they have consumed about three quarters of this a telephone bell will give them the signal to withdraw and dance attendance during the half hour needed for the preparation of the last course, *Café Rechauffé à l'Anglaise* Dinner will be served in four sessions—late, later, latest, and extra—and members will be free to attend any of these, or all four if they're lucky

* * *

At interviews they always ask me why I went into psychiatry, and if I give them the real answer—because I could not make any headway in gynæcology—I do not get the appointment I am after Last time I was even refused the fare from Bootle to Skegness, where I had hoped to see the tail end of a particularly good aurora borealis Since then I have answered the question differently and in a poignant pregnant manner designed to hold the committee spellbound throughout the interview, as a result I have been appointed to no fewer than 31 full-time posts in the last fourteen days

I start my explanation of why I went into psychiatry by recalling my performance as a tenor tot in Turandot at the age of four Instead of this opera, applicants who adopt my method can mention touch typing, Milton's *Defensio Secunda*, their first conker championship, or any other evidence of prodigious ability, according to taste The age, however, is important, and only the very best raconteurs should attempt to raise it above five years or lower it below nine months The aim is to bring a nostalgic tear to the eye of even the dourest committee-man, reminding him of his own long passed childhood and of how bad he was at conkers, let alone opera I then sketch briefly the secondary events of my life that led to the Big Decision—Aunt Ada's Adie's syndrome, my early work on frogs' spawn, and whatever else, appropriate or not, that comes to mind, for by this time the battle is won

My more astute readers will see how, by slightly varying the theme, it is possible to answer such posers as why I went into orthodontics In this case it would be well if an early love for the Wheatstone bridge, or memories of the thrill enjoyed on first sighting the Leaning Tower of Pisa, could be cunningly woven into the fabric of the tale

* * *

The quality of the milk delivered at my home had obviously been deteriorating for some weeks, so I tackled the roundsman about it Was it, I asked, an effect of the shortage of new grass? "Well," he replied after thinking deeply for a minute or two, "it may be that, but to my mind it's because they get too much of this consecrated food" We left it at that

* * *

Any doubts about Medicine's contribution to the Festival pageantry should be set at rest by the vivid description in the *Observer* of May 6

> "In floodlit Trafalgar Square a nose to tail procession of vesicles crept slowly along"

On their way to the gathering at the Institute of Dermatology, of course

Letters to the Editor

OPPORTUNITIES FOR THE DOCTOR IN BRITAIN

SIR,—After two years in the United States we returned to Britain a few weeks ago for personal reasons and also to see what opportunities were open for medical graduates trained in internal medicine. We visited numerous hospitals and discussed the situation at length both with our contemporaries and with senior members of different university teaching staffs. While there were some obvious improvements in the hospital service, such as the upgrading of some hospitals by the provision of better consultant staffs, there were other developments which gave rise to misgivings as to their ultimate effect on the quality of British medicine.

Consultants in training are presented with a definite scheme of promotion which specifies certain periods in different grades. No provision appears to be made, or credit given, for a year or more spent in basic sciences such as pathology, which was previously regarded as a beneficial if not an essential part of the training of specialists. In the same manner a candidate who acquires training of an unusual but useful type, such as biochemistry, may find himself unable to return to the clinical field because his place on the promotion ladder has been filled.

Senior registrars with ten or more years' training find that they may be forced into general practice, for which they are no longer fitted by virtue of their specialisation. Interchange of specialists and general practitioners is no longer practicable. In one hospital that we visited six senior registrars, aged 35–40, nearing the end of their tenure of this grade, were trying without success to obtain posts as specialists. Some graded consultants did not have any hospital beds directly under their control, and were not expected to have them till after the age of 45.

Time spent on acquiring multiple or sometimes initial specialist degrees might be more profitably spent in a special interest such as research or further clinical experience. Some, but not all, such degrees are purely scholastic and do not require any apprenticeship in the subject. These degrees have been given a more important place in the new service than previously.

The ratio of consultants to beds and to general practitioners is low. Some consultants hold multiple appointments, thereby keeping the number down. Many people performing consultant duties are denied the name and prestige of consultant. The standard of general practice is necessarily dependent on the standard of consultant medicine, and economies in this service appear to be false. It is in the hospital mainly that new drugs are discovered and evaluated.

The main result of these difficulties is to cause a feeling of unrest and insecurity amongst those training as specialists. To some extent the direct relationship between effort and initiative and success is lost. The net result with overworked consultants and insecure registrars, must ultimately be a poorer service. The best-trained members of our profession should surely be the last to be dispensed with in the name of economy. Economies might be better made in the compensation now made to those with illness of short duration. We know that those working in hospitals are well aware of these conditions, but we wonder if doctors not engaged in hospital practice and also the general public realise the loss to the community when well trained men are forced to give up their specialty.

In conclusion we should like to thank our friends for their kindness on this visit.

J. MACLEAN SMITH
JEANNE MONTGOMERY SMITH

Baltimore, Maryland, U.S.A.

POLIOMYELITIS

SIR,—I am stimulated to comment on one paragraph of Mr. Le Vay's article in your issue of April 21. It is the one which begins: "However troublesome pain and spasm may be, they must not be allowed to obstruct daily passive movements."

This practice has led to a great deal of unnecessary suffering in the acute stage of poliomyelitis. Whatever the cause of the pain there is nothing to suggest that the spasm is other than a protective mechanism. Passive (and active) movements within a range which does not produce pain are of value from the onset, but beyond this range they should be avoided.

Treatment in the bath and hot packs, which Mr. Le Vay does not mention, are of considerable value in overcoming muscle spasm which persists after the acute stage.

Wingfield Morris Orthopædic Hospital, Oxford. J. C. SCOTT

SPECIALISATION IN TEACHING

SIR,—Despite increasing concern at specialisation the trend continues. It seems to be a deeply rooted feature of modern western civilisation; yet at the same time a need for people with wide knowledge and abilities is felt growingly in numerous fields. A leading article in *Science* about a year ago urged the education of general scientists, and a formidable curriculum was outlined for them. The preservation of sound general medical practice and the suitable training of new general practitioners is a more modest goal, yet one fraught with difficulties. It is a desirable goal for the extremely practical reason that the patient's body is indivisible.

Once past biology in the 1st M.B. examination our education is entirely by specialists—a procession of anatomists, physiologists, pathologists, assorted surgeons, obstetricians, metabolic physicians, and cardiologists—whose various teachings the student is expected to integrate for himself. Except for those few fortunate enough to participate in experiments at teaching general practice to undergraduates—notably those at Edinburgh[1] and Harvard[2]—at no time does the average student come under the influence of a teacher who would describe himself simply as a doctor, able to help him fit his specialised learning into its proper perspective. Many doctors have noted the prestige which specialists gain in the minds of their students by virtue of their position as teachers, but I have not read any comments on the allied, but none the less separate, problem that specialisation is made attractive because Medicine is being taught as a mere collection of specialties irrespective of by whom.

Miraculously most of us graduate with respect for something we call Medicine. Many of us feel that all specialisation entails some retreat from the central theme of Medicine. A few of us who are so persuaded also enjoy teaching and the stimulus of contact with other teachers and clinicians; but little outlet or encouragement is given to teachers who show no inclination to specialise. In both the clinical and the scientific departments of medical schools the selection of staff on their research ability has ensured that they are manned entirely by specialists.

Although the community supports universities primarily that they may teach, scientific departments are commonly organised on the polite myth that all faculty members are principally interested in something other than teaching (usually research) and are prepared to do their stint at teaching much as they are prepared to pay their income tax. It is of course essential that university teachers be able to refresh their teaching from some other activity, but need it necessarily be a specialty? Cannot some way be found whereby teachers can be general practitioners or vice versa?

---

[1] See Scott, R. *Lancet*, 1950, ii, 695.

[2] See leading article. *Ibid*, p. 659.

Scientific, especially medical scientific, departments often carry one or two men regarded as "passengers" by their colleagues because they do no research or at least publish none I strongly suspect that a proportion of these men have got into academic medicine not realising in the first place how far away it would take them from the humanitarian side of their profession They are inactive in research because of a reluctance to specialise beyond a certain point which their general medical training disposes them to find the limit compatible with a humanitarian, as opposed to a scientific, outlook Only in their teaching can they feel sure that they are doing something of definite value to society

The more widespread teaching of general medicine to undergraduates would not only benefit the latter but might also provide an outlet for doctors with an urge to teach without having to make a pretence at embracing some specialty

Holbeach Lincolnshire A J RICHARDS

THEORY OF CEREBRAL LOCALISATION

SIR,—I agree with Dr Jefferson's thesis (April 28) that the results of hemispherectomy call only for a renewal of attention to already established, though recently unemphasised, clinical and experimental observations, rather than for any radical revision of theories of cerebral localisation , but the effects do not seem to me to argue against Jackson's view that destructive lesions cause negative symptoms

The clinical and electrical evidence suggests that the damaged hemisphere as a whole constitutes in Jacksonian terms a "discharging" quite as much as a "destructive" lesion The results of removal are essentially negative —namely, a reduction of abnormal discharge The beneficial effect on the remaining cerebral economy reflects the extent of the abnormal discharge removed Although, apart from the visual sphere, the evidence does not as yet reveal any clear loss of "normal" function, I would hazard a guess that further study will enable us to see something of that too though it may weigh very light in the balance of over all benefit to the patient

Oxford C W M WHITTY

SIZE OF MEDICAL SCHOOLS AND HOSPITALS

SIR,—I was interested in the letter from "Calculus" in your issue of April 21

I took my 1st M B work at Toronto University, in a class of 150 students Since then I have been at the Middlesex Hospital in London, where classes have averaged 45

At Toronto two shifts of 75 students were formed for practical classes These were each attended by the respective professors, assisted by three demonstrators In the physics and chemistry departments practical books were handed in for examination once weekly, and were verbally corrected at the next class In biology the last fifteen minutes of each three hour session was spent in a more or less informal viva from professor or demonstrator (working in rotation through the whole class), for which marks were assigned, these marks being considered when assessing the students' examination results in the first year final examinations Furthermore the chemistry professor within the first six weeks of the autumn term could accurately fit name to face of all of the 150 students This was achieved by assigning to each student a numbered seat in the lecture theatre, and the professor having on his desk a plan of the seats with the students' names entered on it Also, if any student missed a lecture in a subsequent practical period the professor saw to it that that student understood the substance of the lecture that he had missed

In physiology I had the good fortune to be taught by Prof Samson Wright and Dr (now Professor) D Slome Physiology, as taught by them, was not isolated studies of nervous system, circulation, digestion, &c Each field was discussed in relation to the others, and through all, by a rapid-fire question and answer technique, we were taught to think rationally and for ourselves

These experiences lead me to conclude that the complex graphs and statistics mentioned by "Calculus," of which I have even less understanding than he, are not the only factors in deciding how a big medical school ought to be Good teachers are essential, and come before problems of capital outlay, running costs, and so on It is not true that a personal relationship cannot be established in large classes or that two people cannot adequately teach physiology, when first class teachers willing to work at their job, can be found

London N W 3 ROY MOTTRAM

HYPERCALCÆMIC URÆMIA WITH NEPHROCALCINOSIS

SIR,—The interesting case recorded by Dr Fulton and Dr Paget (April 21) is surpassed by one described by Albright[1] This was of a man of 50 who had a single metastasis of the right ilium and sacrum from a "hypernephroma" of the kidney, associated with hypercalcæmia and hypercalciuria The interesting part of the story is that the serum and urinary calcium values went back to normal when the metastasis was irradiated, only to rise again when the condition relapsed

Dr Fulton and Dr Paget suggest that "the syndrome only develops in cases in which the bony secondaries are of sufficiently wide distribution or long duration" This cannot be, as in Albright's case they were not widely distributed , and their comparatively rapid response to irradiation with subsequent relapse shows that long duration is not important It is probably all a question of how quickly bone is being destroyed

Department of Pathology

OLIVER C LLOYD

FOOD AND ENERGY

SIR,—It is now some centuries since the scientific method of observation and experiment replaced authoritarianism, but I sometimes wonder whether the replacement was complete or whether the wheel is turning full circle For we continually meet with statements made, or uncritically quoted, by men of authority which, when subjected to scientific criticism, turn out to be no more than expressions of opinion When such statements of a technical nature are made by people not skilled in the relevant branch of technology there is at least the excuse of ignorance, but it ill becomes the expert to lend his authority by quotation which implies tacit approval

In his letter of March 10 Dr Franklin Bicknell, possibly with caution but certainly with subtle emphasis, quoted without comment from the report of the Productivity Team on Rigid Boxes and Cartons to the effect that diet plays an important part in enabling the American worker to work faster and to sustain the effort Dr Bicknell, with an accuracy which is unusual in such quotations, gave the entire relevant section of the report There is nothing in the report to substantiate this surprising claim, which turns out to be a statement of opinion, if not of prejudice, and not of fact

The only piece of what might purport to be evidence is that members of the productivity team were able to work all day without fatigue While the layman might be excused for putting this down to the first cause that comes to mind—namely, food—Dr Bicknell must surely agree that change of environment, change of working conditions, intellectual stimulus, new interests, to mention but a few might equally be responsible for the absence of fatigue

THE PHYSIOLOGY OF SLEEP

SIR,—In my article of March 17 on Professor Hess's work I made some errors in describing the sleep producing area of the thalamus It would be more accurate if the relevant sentence read "This [sleep] only occurs after stimulating the hypnogenous zone, which is in the thalamus beside the massa intermedia and about 2 mm from the midline" In Hess's most detailed account of his sleep experiments [1] the area is defined as follows

> The upper and lower limits correspond to the lower half of the massa intermedia (which in cats is a constant landmark) The medial border is 2 mm from the midline The anterior and posterior limits are the tracts of Vicq d Azyr and of Meynert respectively The lateral border cannot be defined so certainly but is within the thalamus

More recent work in Zürich, which I have been privileged to see in the last few weeks, has modified this description slightly in two respects First, the zone extends dorsally to the upper limit of the massa intermedia Secondly, the most evocative zone is quite narrow and may be confined to the lamina medullaris interna

This is my interpretation of work that has only been published as a brief communication.[2] It shows that the sleep produced by stimulating the hypnogenic zone is not only normal by biological standards, but also produces the changes in the electro encephalogram that accompany natural sleep I hope that this important contribution to the study of sleep will be published in extenso and in English

St Bartholomew's Hospital London E C 1 — **DONALD A MCDONALD**

POTASSIUM AND SODIUM BROMIDE

SIR,—The recent announcement, that sodium bromide may be dispensed by chemists in place of the potassium salt when supplies of the latter are not available to meet N H S *prescriptions, should receive the widest publicity* among doctors

Patients with congestive heart failure, hypertension, pre eclampsia, or obesity are commonly ordered a salt-restricted diet If, at the same time, the doctor should prescribe one of the several mixtures containing potassium bromide and the chemist supplies the sodium salt, the intake of sodium ion is likely to be sufficient to defeat the purpose of the diet In such circumstances doctors should endorse their prescriptions "not sodium bromide"

Woldingham Surrey — **L M SPALTON**

A PATIENT'S VIEW OF RADIOGRAPHY

SIR,—Mr A, who has had disseminated sclerosis for nearly ten years and goes about in a wheeled chair, recently felt a pain, described by him as very slight, in the left hip and knee *At once* he began to hope that X ray examination of those joints might reveal the cause and lead to cure of all his symptoms

He applied to his general practitioner, who without discussion gave him a note for a consultant in the general medical outpatient department of the local hospital This second doctor observed that Mr A. had formerly attended the neurological clinic, and again without discussion referred him back there, where at a later date I saw him accompanied by his wife

After examining him I explained that there were no signs of disease of hip or knee, that the seat of the trouble, now as before, was the spinal cord and that unfortunately the proposed X-ray examination could not help

Mrs A — I think he ought to have it to set his mind at rest '

I— I'm sorry but I have a duty not to order X rays which I think unnecessary You must let me set his mind at rest '

Mrs A —" It's very hard on us with so little money coming in It s a shame "

I—" Your situation is hard and I sympathise, but have you thought who would pay for the X rays ? "

Mrs A (astonished at my ignorance)—" *Nobody* pays for them ! They come from the Government '

Mr A (*getting down to brass tacks*)—" *I look at it this* way Those X rays cost, say, fourpence each If I could have them and they got me back to work I could pay for them easy I d be glad to "

Have we no more economical means of ridding a patient of notions like these (which I believe I dispelled without ill feeling) than to book two appointments at a hospital for him, take him there and back twice by car, and give him interviews with *three doctors, including* his own ?

London W 1 — **JOHN PENMAN**

CYANOSIS IN INFANTS FROM NITRATES IN DRINKING-WATER

SIR,—In their article of April 28 Dr Ewing and Dr Mayon White describe cyanosis in infants caused by nitrate in drinking water They suggest that some of the reported cases of familial idiopathic methæmoglobinæmia might really be due to the same cause, and they imply that the family we described,[1] living on a mountain farm and containing five affected members, all adults, might come into this category

Three of the affected members of this family had lived for considerable periods away from home (one as an employee in a large hospital), but no recovery from the symptoms had followed the change in water supply Moreover, Dr Ewing and Dr Mayon White are evidently unaware of further work on this family [2] in which it was shown that the methæmoglobinæmia was due to an enzyme deficiency in the erythrocytes The same enzyme deficiency was found in the affected brother and sister in a family we have just described in your columns [3] This family used the main water supply of a large town

We feel that on the present evidence there is no reason to depart from the generally held view that "well-water cyanosis" is an environmental disease of infancy Familial idiopathic methæmoglobinæmia, on the other hand, is due to an inborn biochemical error, the symptoms of which usually, though not invariably, appear in infancy and persist, unless treatment is instituted, into adult life

Department of Biochemistry
Queen s University Belfast.

D C HARRISON
Q H GIBSON

SIR,—The interesting article by Dr Ewing and Dr Mayon White prompts me to record briefly a similar case The condition is probably not rare in rural areas.

In November 1950 a 3 week old male infant was referred to hospital by Dr A. H Cheshire, of Brewood, South Staffs The infant was the fifth child, and all the others had been reared in the same cottage, which was in a country lane some distance from the nearest dwelling

He was born about 2 weeks prematurely, and at birth weighed 6 lb 2 oz At 10 days of age he was taken off the breast and put on to a dried milk mixture He was described as lusty, but had been jaundiced from a few days after birth Soon after being put on the bottle his skin became dusky, and discoloration increased up to the time of his admission to hospital

On admission he showed a peculiar slaty cyanosis tinged with faint jaundice and he appeared pale weight 6 lb 15 oz *Physical examination* was negative apart from a soft systolic murmur

Investigations —Urine normal Radiograph of chest normal Blood Hb 55%, red cells 2,940 000 per c.mm white cells 12,700 per c.mm (polymorphs 41%, lymphocytes 57%, monocytes 2%) Blood group A, rhesus positive, Coombs test negative - *Considerable amount of methæmoglobin*

present (absorption band at 630 mμ abolished by sodium hydrosulphite). Serum bilirubin 1.8 mg. per 100 ml.

Progress.—The infant's condition was good, and he took his feeds readily; so ascorbic acid 150 mg. daily was given. By the next day the cyanosis was less marked, and it disappeared in 3 days. By the time of discharge from hospital, after 6 days, he appeared normal and weighed 7 lb. 1 oz. His hæmoglobin was 85%.

Now, at the age of 6 months, he has developed normally and cyanosis has not recurred.

The water supply to the cottage came from a shallow well, the water from which was found to contain nearly 400 parts of nitrate per 1,000,000. The probable reason why the other children had not suffered similarly was that they were breast fed for a considerably longer period.

Wolverhampton. H. EVERLEY JONES.

HEARTBURN

SIR,—Heartburn is a troublesome symptom in some patients, so it may perhaps be worth recording that it usually responds to the administration of ferric ammonium citrate (I give ferri et ammon. cit. gr. 5, in plenty of water, p.r.n.). Bismuth carbonate is also frequently effective. These observations suggest that heartburn may be caused by the presence of sulphides in the upper bowel. Ferric salts oxidise sulphides, and bismuth salts form an insoluble precipitate of bismuth sulphide. The *National Formulary* "white mixtures," containing no bismuth, are ineffective in the treatment of heartburn.

Lowestoft. N. B. EASTWOOD.

AN IMMUNOLOGICAL PROTEST

SIR,—It is with regret that I have to point out certain unwarranted conclusions in recent publications by Mr. L. B. Holt. He has made important contributions to immunology by introducing P.T.A.P., by establishing the importance of the amount of carrier in this preparation, and by demonstrating phagocytosis of some of the injected material. His reputation, based upon this work, may lead many readers to accept and sometimes repeat statements in his writings without checking the original papers upon which they were based and without examining critically his experimental data.

For example, writing of "a final baseline level of immunity," he[1] states that "Glenny and Barr 1947"[2] "have reported a similar phenomenon in horses in which tetanus titres were observed over a period of five years following a single inoculation of tetanus toxoid." Tetanus antitoxic titres were not followed in any horse over a period of 5 years nor was there any reference to a horse receiving a single injection of toxoid. There was, however, a horse mentioned that had been *hyperimmunised* with tetanus *toxin* for a period of $5^1/_2$ years which lost very little antitoxin during the first 13 months after injections had ceased. It would also be unfortunate if other writers repeated another statement about tetanus toxoid made by Holt[3] that "we know that no corresponding advantage is gained in preparing an Alum Precipitated Tetanus Toxoid" (p. 144). It is true that two injections of tetanus toxoid at suitable intervals confer good immunity, but the antigenic efficiency of many batches of tetanus A.P.T. is far in advance of that of the original plain toxoid. Glenny, Hamp, and Stevens[4] showed that the addition of 1% potash alum to tetanus toxoid greatly increased the antitoxic responses in guineapigs and horses.

In *Developments in Diphtheria Prophylaxis*[3] Holt has a section entitled "A Critical Review of Glenny's Work"; this "work" consists of a single paper by Glenny, Buttle, and Stevens published in 1931.[5] Those who read this review side by side with the original paper will realise how completely Holt failed to understand the work he criticised and how unjustified he was in saying that "results and comments do not appear to tally or agree with the remarks in the preamble to the paper" or "the same explanation was presented to account for a completely opposite result."

Holt's objection to the use of horse serum in the first experiment shows that he was not aware of the work of Glenny, Hopkins, and Waddington[6] in 1925 nor of that of Glenny and Waddington in 1928.[7] Again his suggestion that guineapig serum should have been used must have been made without any thought of the task of collecting from guineapigs twenty years ago the 2000 units of antitoxin needed for the experiment. In addition, he must have overlooked the statement by Glenny, Barr, Ross, and Stevens[8] that "non avid antitoxin is constantly met with in the serum of guineapigs immunised with diphtheria prophylactics." Such non avid antitoxin would have been most unsuitable for the work described by Glenny, Buttle, and Stevens. There are many more criticisms in the review, all of which can equally be shown to be unjustified. Holt's criticism appears to be directed against the statement "that the improved response due to the addition of alum to toxoid can be attributed to the antigen remaining in the body sufficiently long to continue its action after the tissues have acquired the power of rapid response" (the so called depot theory). Holt himself appears to show that this is true some 17 pages later in his book.

As one of the two authors who first described the primary and secondary response phenomenon, I must protest against the use of the expressions "second" and "tertiary" response. It is inconsistent to speak of primary, second, and tertiary responses and shows a misunderstanding of the *two essential types* of responses.

Wellcome Research Laboratories,
Beckenham, Kent. A. T. GLENNY.

*** We have shown this letter to Mr. L. B. Holt, who replies:

"Mr. Glenny's first point is that I misquoted him in an article I wrote in 1949. Just after the article appeared, Mr. Glenny wrote drawing my attention to the inaccuracy. I replied acknowledging the error and apologised. Since that time I have not had a suitable occasion to rectify the error publicly, and am pleased to take this opportunity to do so now.

"My words 'We know that no corresponding advantage is gained in preparing an Alum Precipitated Tetanus Toxoid' are part of a statement concerned with the discovery by Glenny et al. of the greatly enhanced potency of alum-precipitated diphtheria toxoid over its parent formol toxoid. I wrote:

> 'From a purely physiological aspect this phenomenon is probably best put into perspective as one emphasising the low degree of physiological activity of diphtheria formol toxoid as a primary stimulus. We know that no corresponding advantage is gained in preparing an Alum Precipitated Tetanus Toxoid, and that Tetanus Formol Toxoid, per se, is an excellent antigen.'

"The full heading of the section of my book which Mr. Glenny mentions is 'A Critical Review of Glenny's Work and His Explanation for the Enhanced Potency of A.P.T.' The subject matter of this section is the enhanced antigenic activity of A.P.T. compared with formol-toxoid. This section is introduced by four relevant references to Glenny's work and deals in detail with a fifth,[5] the only one (to my knowledge) in which he and his co-workers describe experimental work on this subject and in which an explanation of the findings is given. The alleged unjustness of my remarks concerning some of the explanations given in this paper by Glenny, Buttle, and Stevens should perhaps be left to others to assess.

"Regarding the use of horse antitoxic serum, my criticism was:

> 'It is thought highly probable that the use of foreign protein antitoxin itself must have considerably modified

> the response of guinea pigs to the initially injected toxoid quite apart from its being the specific antibody to the primary antigen used it follows that guinea pig antitoxin should have been employed in order to avoid the use of foreign protein antitoxin (Ref 3 p 74)

That the criticism seemed valid, but was unfounded, is shown in the fact that Inga Scheibel repeated the experiment, using homologous antitoxin, and obtained the same results as Glenny et al who used heterologous antitoxin. This is referred to on p 163 in my book The fact that Mrs Scheibel repeated the experiment with homologous antitoxin would seem to answer the point about the low avidity of guineapig antitoxin

“ Concerning the ‘ depot theory,’ although on p 90 of my book it is shown that a single *large* inoculation of P T A.P does result in a (superimposed) secondary response—i.e , the inoculum operates over a long enough period to produce a secondary response—it is also shown that the secondary response makes little contribution to the far more important ‘ base line ’ titre The further observation that the amount of toxoid (provided the *very small essential minimum* is used) associated with the optimal amount of $AlPO_4$ carrier makes no material difference to the 12 week antitoxin level argues even more strongly against the suggestion ‘ that the improved response due to the addition of alum to toxoid can be attributed to the antigen remaining in the body sufficiently long to continue its action after the tissues have acquired the power of rapid response Even so, this suggestion has been exhaustively analysed and an alternative offered which has a basis expressed in physiological terms (p 67 et seq)

“ Immunologists are all aware of the classical paper of Glenny and Südmersen,[9] describing the ‘ primary and secondary response ’ phenomena—an observation of fundamental importance Mr Glenny has also described other types of response I too have described another —that following a third inoculation of potent material —which was different from the typical primary or secondary response, and I quite simply labelled it “ tertiary ” response (Ref 3, p 160) No doubt other types of response will be described in the future The expression ‘ second response ’ was used to denote the response to the second injection only—to distinguish it from *any* secondary response The term seemed valid, because ‘ secondary response ’ has come to mean the response to any injection subsequent to an efficient primary stimulus,’ and not all such secondary responses have exactly the same character The greater part of my work has been and is, an attempt to gain an insight into the physiological basis of these phenomena , my observations lead me to suspect that they are more complex than would be implied in ‘ two essential types of responses ’ ”—ED L.

MUNCHAUSEN'S SYNDROME

SIR,—You may like to learn that Munchausen's syndrome is not confined to Great Britain In Sweden similar frauds are headlined as “ Köpenickiades ” after the German town of Köpenick—the scene of a famous hoax in 1906 However, I gladly accept Dr R A. J Asher's term, though, like Dr Paul Wingate, I feel that the noble baron would not have approved of the company , and I should like to describe two examples of the syndrome that I have seen

CASE 1—This patient belongs to the subspecies laparotomophilia, with possible motives 2 and 5 he is known to most of the doctors in central Sweden as ‘ X son with the ship ’ because, unfortunately for him, he has a large ship tattooed on his chest In 1924 he was operated on for a perforated duodenal ulcer, and since then he has been admitted innumerable times to all the hospitals in and around Stockholm with the symptoms of an acute perforation. If recognised he would promptly drop the pretence and say ‘ I see there's nothing doing this time ” , and he would then dress and leave quietly Often he deceived the doctors and got free board and lodging for the night Although he managed to avoid an operation he was not afraid of one but usually he was discharged in a few days or discharged himself, taking the hospital soap with him. I first heard of him in 1933 when I was a student, and later met him several times and saw his name on all the hospital black lists in Stockholm I had almost forgotten him when he arrived at this hospital (70 miles from Stockholm) On two occasions he attended with a fake coronary thrombosis The second time I had the honour of dealing with him, and I do not think he will return again

There is a story concerned with this case which illustrates the dangers of a too hasty conclusion

A patient who gave the name of “ X son ” entered a hospital in Stockholm and complained of the symptoms of a perforated duodenal ulcer He was seen by an inexperienced medical student, who telephoned the doctor in charge for advice He was told to look for a tattooed ship on the patient's chest, and when this was found the patient was discharged A few hours later he returned, and this time there was no doubt about the diagnosis Unfortunately the wrong “ X-son” with the wrong ship had been thrown out

CASE 2—Fifteen years ago a patient was admitted to a Stockholm hospital with pyrexia of unknown origin. He was a pleasant youngish man who gave his name as Ondonte van der Tockayernnie, and said that he was a Spanish nobleman of an old family which had returned to Spain with the Duke of Alba after the liberation of the Netherlands After admission to hospital he continued to run a high continuous fever, which was attributed to infected lower teeth These were extracted without effect on the fever Then osteitis was suspected, and the jugular vein was ligated (this was before the sulphonamide era) , but he continued to run a temperature Finally half the mandible was removed, but the fever continued. The patient remained unperturbed and pleasant By the time he was caught manipulating the thermometer the police had discovered that he was a wanted criminal with a common Swedish name and several aliases

The remarkable thing about this patient was that he could not reasonably have believed that it was possible to carry on the fraud to his advantage

SVEN GÖSTA SJÖBERG

EXPERIMENTS ON FAT ABSORPTION

SIR,—I read with interest last week's paper by Dr Auld and Dr Needham Perhaps they and readers would be interested in two experiments I performed 5–6 years ago when I was surgical chief assistant and resident surgical officer at the Christie Hospital and Holt Radium Institute, Manchester

At the completion of two left block dissections of the neck I introduced a fine rubber tube into the distal end of the bisected thoracic duct I did this because I was interested in the total daily flow of chyle and to find out what happened when these patients were given a fatty meal So far as I can recall the total chyle drained in 24 hours after operation was 350 ml in one patient and 400 ml in the other When fatty meals were given the rate of flow increased from 350 to 500 ml and from 400 to 550 ml per day specimens became more ‘ milky, and the amount of fat in each case doubled In the fasting specimens fatty acids were present, but their amount increased after a fatty meal Unfortunately, after the second day the tube came out during change of dressings , but the opening sealed off almost immediately, and neither patient suffered or was delayed in hospital At that time I did not have the opportunity to continue further research in this line, and I have misplaced the detailed analyses of the specimens I collected

I see no objection to placing a cannula in the thoracic duct in patients undergoing, say, a cervical sympathectomy or a block dissection of the neck The patients appear to suffer no inconvenience, and specimens for analyses can be collected from the duct after the ingestion of fats The chyle collected may or may not represent the total flow through the thoracic duct, which will depend on how freely the duct communicates with the venous and lymphatic systems and the ease of flow through these anastomotic channels

The above two patients were admitted to hospital under the care of my chief, Mr W R Douglas

Royal Hospital Sheffield
DAVID AIKEN

PARAFFIN IN SYRINGES

SIR,—In his letter last week, Dr Woodmansey presses concern that syringes supplied ready for use e lightly lubricated with liquid paraffin, as suggested the *M R C memorandum* quoted by Dr McCartney Iarch 3)

Although some centres claim that no lubricant what er is required we have found that the loss of syringes r jamming is less when a lubricant is used, and that uid paraffin is an efficient lubricant provided that only very slight *trace is applied to the piston of the syringe* us may be done easily and routinely by dipping the d of the piston into a solution of liquid paraffin (1 ml) trichlorethylene (1 lb) The piston is then inserted to the barrel and worked up and down for a second or o until the trichlorethylene evaporates The film of uid *paraffin remaining is infinitesimal so that the risks* umerated by Dr Woodmansey are obviated

W TRILLWOOD
Director of Pharmaceutical Services,
United Oxford Hospitals

Churchill Hospital Headington, Oxford

ACTION OF DIPHENYLHYDANTOIN SODIUM ON THE ADRENAL GLAND

SIR,—Six epileptics under treatment with diphenyl dantoin sodium ('Dilantin Sodium') have been idied They received the drug in doses of 2 6–6 5 g per kg *body weight per day In addition* most of em were receiving phenobarbitone daily *With* 1 ception these drugs had been given for more than a ar before the investigation started

All 6 patients (2 men and 4 women, aged 17–37 years) d gingival hypertrophy which has continued to ogress Tissue biopsies showed *that the hypertrophy* iefly involved the connective tissue and that the tivity of alkaline phosphatase present there was eater, especially in capillaries, *than* in similar tissue tained from control subjects who were not epileptics d who received no therapy Skin reactions were also served, and there was some evidence that diphenyl dantoin sodium caused a relative lymphocytosis

In view of these findings, and of the evidence that caline phosphatase activity and collagen formation are luenced by hormones of the pituitary adrenal complex,[1] was decided *to study the effect of* diphenylhydantoin lium on mice, and to examine particularly the adrenal inds It has already been shown that diphenylhydan n sodium can produce slight adrenal hypertrophy in e guineapig[2]

In a preliminary series of experiments 15 mg per kg body- ight per day was given to the animals by intraperitoneal ection over a period of 120–125 days, at the end of which animals were killed Controls received an equal volume 0 9% sodium chloride solution (The daily supplement Na+ received by controls was always greater than that en as diphenylhydantoin) All the treated animals showed *tensive pathological changes in the adrenal glands* In e animal there was hypertrophy only in the others, sides hypertrophy, asymmetrical degenerative changes were served, *chiefly in the fascicular zone but also in the* merular zone and the medulla The adrenals of the itrols did not show these changes In these mice there s no hypertrophy of the gingival tissues

If the reactions *observed do not result merely from* e application of a non specific "stressor," then the estion arises whether the action of diphenylhydantoin dium and perhaps other anticonvulsants may not be cribed to some interference with the pituitary adrenal mplex either by *action on the central nervous system* at some intermediate point In addition, diphenyl hydantoin sodium may inactivate circulating hormones of the pituitary adrenal complex or potentiate their action on tissues by some hitherto unsuspected peripheral action, perhaps on capillaries *It may be noted that in rats deoxycortone acetate has already been shown to* reduce the excitability of the central nervous system, excitability can be restored to normal by simultaneous administration of A C T H or whole extract of the adrenal cortex[3]

Diphenylhydantoin sodium, then, would *appear to* have some use as a physiological tool to study the pituitary adrenal complex Finally, these results may throw some light on the mechanism responsible for clinical epilepsy Further work is in progress

PUBLICITY IN CANCER

SIR,—As Mr Patey points out in his letter last week, the word "early" as applied to malignant disease is ambiguous

The only criterion of an early case, in my opinion, is *that the malignant state is still confined to its site of* origin Any clinical manifestation is, for the most part, an indication that the disease is established and its extent doubtful In cases of a lump in the breast, how ever, suitable publicity might well be helpful in pointing out that absence of pain does not mean *freedom from* danger

London W 1

F D SANER

CATION-EXCHANGE RESINS

SIR,—May I reply to the comments of *Dr MacIntyre* and Dr Jordan (April 28) on my *article of April 14 on the* cation exchange resin 'Zeo Karb 225'

In the first place I must point out that I avoided any discussion of the physicochemical aspects *of cation* exchange, since I considered the subject too *specialised* for your journal The data and my *observations were presented in the* simplest possible manner with the object of providing clinicians and others with some practical quantitative information on the resin, particularly in view of the somewhat scanty literature on *the subject as* a whole in medical journals

As Dr MacIntyre and Dr Jordan remark, *the data* for the sodium hydrogen exchange system *show that the* reaction obeys the law of mass action, the values for the equilibrium constant KH/Na for the range of concentra tions studied varying between the limits 3 18–3 38 From the theoretical *point of view*, saturation of the resin with sodium would never reach completion under the con ditions of my experiments Consequently the suggested conditions for full saturation and 100% *efficiency* of sodium exchange were intended only as an approximation, and *were indeed* deduced by extrapolation *of curves* based on only a few experiments

As regards the exchange in sodium calcium *systems*, one can determine the equilibrium conditions *from* the relevant physicochemical *constants* But in some of my experimental systems as many as four cations were in competition for the absorptive seats on the resin, under which circumstance direct observation of the equilibrium conditions is probably simpler to perform *than the corresponding mathematical* analysis Further, in systems of univalent bivalent cation exchange the exchange isotherm is not independent of *the absolute* concentration of the two ions in the aqueous phase as it is in univalent univalent *systems—a property* which *leads to* mathematical complications in systems *involving* calcium

Finally, I would like to point out *that* removal of hydrogen ions from the exchanger solution as they are

released from the resin, apart from being desirable from the physiological point of view, should lead to greater exchange efficiency of the resin by exclusion of their competitive effect in the reaction As I have reported, magnesium trisilicate has proved unsuitable for this purpose, but other possibilities in this direction are being considered

Selly Oak Hospital Birmingham F MORTON

Parliament

National Health Service Bill

IN the House of Commons on May 2 this Bill was considered in committee On clause 1, Mr J ENOCH POWELL moved an amendment to lay the duty of assessing the charge for appliances according to the means of the patient on the regional hospital boards or the local executive councils, instead of the National Assistance Board Mr FRED MESSER also disliked the assessment being undertaken by the N.A.B , but thought that Mr Powell's proposal would add to the existing inconsistencies of the National Health Service What would happen, for instance, to patients who entered teaching hospitals ? He foresaw that the regional boards would have to do the work through their management committees, which he deprecated Dr CHARLES HILL was filled with dismay at the suggestion of adding still further to the functions of the local executive councils Mr ARTHUR BLENKINSOP, parliamentary secretary to the Ministry of Health, believed Mr Powell's proposal to be impracticable The only way which was administratively feasible, and which would avoid waste, was to use the staff and offices already available The N.A.B , for instance, already dealt with claims for refund of N H S travelling allowances and were in closer contact with the public than the regional boards or local executive councils. The amendment was by leave withdrawn

THE STRANGER WITHIN OUR GATES

Mr E H KEELING moved an amendment providing that visitors, whether of British or foreign nationality, should pay in full both for spectacles and false teeth Two years ago it was estimated that the cost of providing health services to visitors was £200,000 The patient's national registration number was given on every application for teeth or spectacles Surely it would not be any hardship to ask him actually to produce his identity card, when the optician or dentist could tell at a glance whether the patient was a visitor

Mr HILARY MARQUAND said he already possessed statutory powers to recover charges for dentures and spectacles from non-residents The powers had not been used because there were grave administrative difficulties in the way The optician or dentist had no power to insist on the disclosure of a patient's national registration number If a practical method could be devised he would be willing to consider whether charges for medical treatment might be made to foreigners About 700,000 foreigners visited this country in 1950, and it was calculated that possibly about 55,000 obtained treatment under the service

Mr ANEURIN BEVAN said that the estimate of the cost of treatment to foreign visitors was wholly surmise, and the figure of £200,000 could be assumed to be higher than the actual figure The amendment was mean in spirit and intention. The Minister would be going far beyond the original intention if he exercised his ingenuity to make regulations to put charges on foreigners who used the health service There was much pressure behind the amendment, it was that certain elements of the medical profession would be able to charge fees. (Cries of " Oh ! ") If he were asked to put his finger on where abuses in the health service took place, Mr Bevan said, he would single out the manipulation of fee-paying beds by specialists in hospitals There was more abuse from that than in any other part of the service Abuses also took place often among the dentists and opticians in the National Health Service, which had not yet existed long enough to eradicate commercialism from the medical profession. One of the results of having a good health service and good nutritional standards was that we had not a large experience of some epidemic diseases on which to train our doctors It might therefore become necessary, and indeed before he left the Ministry of Health he had discussed this with his medical advisers, for us to bring patients from different parts of the Colonial Empire to be treated in Britain

Dr HILL thought this was much ado about nothing He did not think that the visitor to this country regarded it as necessary, reasonable, or sensible that part of the hospitality we provided should be free dentures and spectacles The amendment was negatived by 285 votes to 254

Mr MESSER moved an amendment to provide that free spectacles and dentures should be supplied not only to hospital patients but to anyone " under medical treatment in any institution or in his own home " Mr BLENKINSOP agreed that there were real anomalies between one category and another Mr Messer's proposed exemption would be too wide, but Mr Blenkinsop agreed to consider sympathetically, though not very hopefully, whether any easement in the position could be made The amendment was withdrawn

A TRIAL RUN

Dr BARNETT STROSS moved an amendment to put a term to the contemplated charges They should, he proposed, only continue in force until March 31, 1952, unless Parliament otherwise determined Mr MARQUAND found it difficult to see how the nation's economic situation could change sufficiently in one year to enable us to withdraw the charges But he sympathised with the view that there should be a review after a reasonable period to see whether the need still existed One year's experience would be too short, and they would require two full years' working of the charges to measure their effects Then they could see, for instance, whether there had been any improvement in the school dental service, and how hospital expenditure was moving He would introduce a new clause on the report stage to bring the charges to an end in April, 1954

The clause was ordered to stand part of the Bill by 262 votes to 3

On clause 2 Mr BLENKINSOP accepted an amendment, moved by Mr MESSER, to ensure that no increase could be made in the charges laid down in the Bill without legislation, though reductions could still be made by order in council

TREATMENT ABROAD FOR THE TUBERCULOUS

On the question that clause 3 stand part of the Bill Mr MESSER said it ought to be understood that Switzerland had nothing to offer this country in the way of positive treatment So far as surgical work was concerned, for instance, we had not merely as good but better surgeons But there was a type of tuberculosis which could be better treated in Switzerland, and he hoped that the Government would give consideration to that aspect He feared many would be disappointed at the number of cases they would be able to send to Switzerland, and it would be wrong to delude tuberculosis patients with the hope that they would be able to get immediate treatment more quickly now Regional hospital boards, he understood, would select the type of case to be sent and it would be difficult to say who should have priority

Lieut -Colonel WALTER ELLIOT said that although this provision might be small it was something To choose patients was not so difficult as not being able to make a choice at all It was true that Switzerland was not a better country for the treatment of tuberculosis than our own, but it had staff and beds and that was the essential thing " Let us bring the two together as rapidly and as extensively as possible " Miss MARGARET HERBISON, joint under-secretary of State for Scotland, said that though the number of beds available at present was small the clause was evidence of the Government's determination to conquer a grave social problem They had chosen respiratory cases in an attempt to bring down the incidence, because these were the cases where there was a fear of infection This clause and the remaining clauses were ordered to stand part of the Bill.

On there committal of the Bill on May 7 Mr MARQUAND, in fulfilment of his promise to Mr Messer to reconsider the wording of the provision exempting hospital inpatients

PARAFFIN IN SYRINGES

SIR,—In his letter last week, Dr Woodmansey expresses concern that syringes supplied ready for use are lightly lubricated with liquid paraffin, as suggested in the M R C memorandum quoted by Dr McCartney (March 3)

Although some centres claim that no lubricant whatever is required we have found that the loss of syringes by jamming is less when a lubricant is used, and that liquid paraffin is an efficient lubricant provided that only a very slight trace is applied to the piston of the syringe This may be done easily and routinely by dipping the end of the piston into a solution of liquid paraffin (1 ml) in trichlorethylene (1 lb) The piston is then inserted into the barrel and worked up and down for a second or two until the trichlorethylene evaporates The film of liquid paraffin remaining is infinitesimal so that the risks enumerated by Dr Woodmansey are obviated

ACTION OF DIPHENYLHYDANTOIN SODIUM ON THE ADRENAL GLAND

SIR,—Six epileptics under treatment with diphenyl hydantoin sodium ('Dilantin Sodium') have been studied They received the drug in doses of 2 6–6 5 mg per kg body weight per day In addition most of them were receiving phenobarbitone daily With 1 exception these drugs had been given for more than a year before the investigation started

All 6 patients (2 men and 4 women, aged 17–37 years) had gingival hypertrophy which has continued to progress Tissue biopsies showed that the hypertrophy chiefly involved the connective tissue and that the activity of alkaline phosphatase present there was greater, especially in capillaries, than in similar tissue obtained from control subjects who were not epileptics and who received no therapy Skin reactions were also observed, and there was some evidence that diphenyl hydantoin sodium caused a relative lymphocytosis

In view of these findings, and of the evidence that alkaline phosphatase activity and collagen formation are influenced by hormones of the pituitary adrenal complex,[1] it was decided to study the effect of diphenylhydantoin sodium on mice, and to examine particularly the adrenal glands It has already been shown that diphenylhydantoin sodium can produce slight adrenal hypertrophy in the guineapig[2]

In a preliminary series of experiments 15 mg per kg body-weight per day was given to the animals by intraperitoneal injection over a period of 120–125 days, at the end of which the animals were killed Controls received an equal volume of 0 9% sodium chloride solution (The daily supplement of Na+ received by controls was always greater than that given as diphenylhydantoin) All the treated animals showed extensive pathological changes in the adrenal glands In one animal there was hypertrophy only, in the others, besides hypertrophy, asymmetrical degenerative changes were observed, chiefly in the fascicular zone but also in the glomerular zone and the medulla The adrenals of the controls did not show these changes In these mice there was no hypertrophy of the gingival tissues

If the reactions observed do not result merely from the application of a non specific "stressor," then the question arises whether the action of diphenylhydantoin sodium and perhaps other anticonvulsants may not be ascribed to some interference with the pituitary adrenal complex either by action on the central nervous system or at some intermediate point In addition, diphenylhydantoin sodium may inactivate circulating hormone of the pituitary adrenal complex or potentiate thei action on tissues by some hitherto unsuspected periphera action, perhaps on capillaries It may be noted that i rats deoxycortone acetate has already been shown t reduce the excitability of the central nervous system excitability can be restored to normal by simultaneou administration of A C T H or whole extract of the adrena cortex[3]

Diphenylhydantoin sodium, then, would appear t have some use as a physiological tool to study th pituitary adrenal complex Finally, these results ma throw some light on the mechanism responsible fo clinical epilepsy Further work is in progress

PUBLICITY IN CANCER

SIR,—As Mr Patey points out in his letter last week the word "early" as applied to malignant disease i ambiguous

The only criterion of an early case, in my opinion, i that the malignant state is still confined to its site o origin Any clinical manifestation is, for the most part an indication that the disease is established and it extent doubtful In cases of a lump in the breast, however, suitable publicity might well be helpful in pointing out that absence of pain does not mean freedom from danger

CATION-EXCHANGE RESINS

SIR,—May I reply to the comments of Dr MacIntyre and Dr Jordan (April 28) on my article of April 14 on the cation exchange resin 'Zeo Karb 225'

In the first place I must point out that I avoided any discussion of the physicochemical aspects of cation exchange, since I considered the subject too specialised for your journal The data and my observations were presented in the simplest possible manner with the object of providing clinicians and others with some practical quantitative information on the resin, particularly in view of the somewhat scanty literature on the subject as a whole in medical journals

As Dr MacIntyre and Dr Jordan remark, the data for the sodium hydrogen exchange system show that the reaction obeys the law of mass action, the values for the equilibrium constant KH/Na for the range of concentrations studied varying between the limits 3 18–3 38 From the theoretical point of view, saturation of the resin with sodium would never reach completion under the conditions of my experiments Consequently the suggested conditions for full saturation and 100% efficiency of sodium exchange were intended only as an approximation, and were indeed deduced by extrapolation of curves based on only a few experiments

As regards the exchange in sodium calcium systems, one can determine the equilibrium conditions from the relevant physicochemical constants But in some of my experimental systems as many as four cations were in competition for the absorptive seats on the resin, under which circumstance direct observation of the equilibrium conditions is probably simpler to perform than the corresponding mathematical analysis Further, in systems of univalent bivalent cation exchange the exchange isotherm is not independent of the absolute concentration of the two ions in the aqueous phase as it is in univalent univalent systems—a property which leads to mathematical complications in systems involving calcium

Finally, I would like to point out that removal of hydrogen ions from the exchanger solution as they are

released from the resin, apart from being desirable from the physiological point of view, should lead to greater exchange efficiency of the resin by exclusion of their competitive effect in the reaction. As I have reported, magnesium trisilicate has proved unsuitable for this purpose, but other possibilities in this direction are being considered.

Parliament

National Health Service Bill

IN the House of Commons on May 2 this Bill was considered in committee. On clause 1, Mr J. ENOCH POWELL moved an amendment to lay the duty of assessing the charge for appliances according to the means of the patient on the regional hospital boards or the local executive councils, instead of the National Assistance Board. Mr FRED MESSER also disliked the assessment being undertaken by the N.A.B., but thought that Mr Powell's proposal would add to the existing inconsistencies of the National Health Service. What would happen, for instance, to patients who entered teaching hospitals? He foresaw that the regional boards would have to do the work through their management committees, which he deprecated. Dr CHARLES HILL was filled with dismay at the suggestion of adding still further to the functions of the local executive councils. Mr ARTHUR BLENKINSOP, parliamentary secretary to the Ministry of Health, believed Mr Powell's proposal to be impracticable. The only way which was administratively feasible, and which would avoid waste, was to use the staff and offices already available. The N.A.B., for instance, already dealt with claims for refund of N.H.S. travelling allowances and were in closer contact with the public than the regional boards or local executive councils. The amendment was by leave withdrawn.

THE STRANGER WITHIN OUR GATES

Mr E. H. KEELING moved an amendment providing that visitors, whether of British or foreign nationality, should pay in full both for spectacles and false teeth. Two years ago it was estimated that the cost of providing health services to visitors was £200,000. The patient's national registration number was given on every application for teeth or spectacles. Surely it would not be any hardship to ask him actually to produce his identity card, when the optician or dentist could tell at a glance whether the patient was a visitor.

Mr HILARY MARQUAND said he already possessed statutory powers to recover charges for dentures and spectacles from non-residents. The powers had not been used because there were grave administrative difficulties in the way. The optician or dentist had no power to insist on the disclosure of a patient's national registration number. If a practical method could be devised he would be willing to consider whether charges for medical treatment might be made to foreigners. About 700,000 foreigners visited this country in 1950, and it was calculated that possibly about 55,000 obtained treatment under the service.

Mr ANEURIN BEVAN said that the estimate of the cost of treatment to foreign visitors was wholly surmise, and the figure of £200,000 could be assumed to be higher than the actual figure. The amendment was mean in spirit and intention. The Minister would be going far beyond the original intention if he exercised his ingenuity to make regulations to put charges on foreigners who used the health service. There was much pressure behind the amendment; it was that certain elements of the medical profession would be able to charge fees. (Cries of "Oh!") If he were asked to put his finger on where abuses in the health service took place, Mr Bevan said, he would single out the manipulation of fee-paying beds by specialists in hospitals. There was more abuse from that than in any other part of the service. Abuses also took place often among the dentists and opticians in the National Health Service, which had not yet existed long enough to eradicate commercialism from the medical profession. One of the results of having a good health service and good nutritional standards was that we had not a large experience of some epidemic diseases on which to train our doctors. It might therefore become necessary, and indeed before he left the Ministry of Health he had discussed this with his medical advisers, for us to bring patients from different parts of the Colonial Empire to be treated in Britain.

Dr HILL thought this was much ado about nothing. He did not think that the visitor to this country regarded it as necessary, reasonable, or sensible that part of the hospitality we provided should be free dentures and spectacles. The amendment was negatived by 285 votes to 254.

Mr MESSER moved an amendment to provide that free spectacles and dentures should be supplied not only to hospital patients but to anyone "under medical treatment in any institution or in his own home." Mr BLENKINSOP agreed that there were real anomalies between one category and another. Mr Messer's proposed exemption would be too wide, but Mr Blenkinsop agreed to consider sympathetically, though not very hopefully, whether any easement in the position could be made. The amendment was withdrawn.

A TRIAL RUN

Dr BARNETT STROSS moved an amendment to put a term to the contemplated charges. They should, he proposed, only continue in force until March 31, 1952, unless Parliament otherwise determined. Mr MARQUAND found it difficult to see how the nation's economic situation could change sufficiently in one year to enable us to withdraw the charges. But he sympathised with the view that there should be a review after a reasonable period to see whether the need still existed. One year's experience would be too short, and they would require two full years' working of the charges to measure their effects. Then they could see, for instance, whether there had been any improvement in the school dental service, and how hospital expenditure was moving. He would introduce a new clause on the report stage to bring the charges to an end in April, 1954.

The clause was ordered to stand part of the Bill by 262 votes to 3.

On clause 2 Mr BLENKINSOP accepted an amendment, moved by Mr MESSER, to ensure that no increase could be made in the charges laid down in the Bill without legislation, though reductions could still be made by order in council.

TREATMENT ABROAD FOR THE TUBERCULOUS

On the question that clause 3 stand part of the Bill Mr MESSER said it ought to be understood that Switzerland had nothing to offer this country in the way of positive treatment. So far as surgical work was concerned, for instance, we had not merely as good but better surgeons. But there was a type of tuberculosis which could be better treated in Switzerland, and he hoped that the Government would give consideration to that aspect. He feared many would be disappointed at the number of cases they would be able to send to Switzerland, and it would be wrong to delude tuberculosis patients with the hope that they would be able to get immediate treatment more quickly now. Regional hospital boards, he understood, would select the type of case to be sent and it would be difficult to say who should have priority.

Lieut.-Colonel WALTER ELLIOT said that although this provision might be small it was something. To choose patients was not so difficult as not being able to make a choice at all. It was true that Switzerland was not a better country for the treatment of tuberculosis than our own, but it had staff and beds and that was the essential thing. "Let us bring the two together as rapidly and as extensively as possible." Miss MARGARET HERBISON, joint under-secretary of State for Scotland, said that though the number of beds available at present was small the clause was evidence of the Government's determination to conquer a grave social problem. They had chosen respiratory cases in an attempt to bring down the incidence, because these were the cases where there was a fear of infection. This clause and the remaining clauses were ordered to stand part of the Bill.

On the recommittal of the Bill on May 7 Mr MARQUAND, in fulfilment of his promise to Mr Messer to reconsider the wording of the provision exempting hospital inpatients from the charges, moved an amendment defining those eligible for exemption as a patient

> "who is resident in a hospital at the time when the appliance is supplied and has been continuously so resident since the examination or testing of sight

Mr Marquand stressed that those who were in pay-beds or in disclaimed hospitals were not exempt from the charges The two groups whom the Government wished to exempt were those for whom the provision of spectacles or dentures was a natural part of treatment in hospitals, and those who were long stay or chronic hospital patients But Members were very dissatisfied with his proposal Dr HILL thought it involved the innocent patient in a gamble as to whether the appliance arrived during his stay in hospital Mr LESLIE HALE suggested that a man with a broken leg could get false teeth while in hospital, while people were often not long in hospital for an ophthalmic operation Mr MESSER himself could only see difficulties arising from the amendment, and he admitted he preferred the Bill in its original form The amendment was formally negatived

Mr MARQUAND moved a new clause fixing April 1, 1954, for the date of expiry of the Act, unless the House expressly resolved otherwise

MAINLY FINANCIAL

In the debate on the third reading Mr HUGH LINSTEAD described the charges as a recognition by the Cabinet that the health service had had more than a proper share of our resources and that it was right that the excess should now be met by the user and not by the taxpayer He regretted, however, that the charges fell so heavily on two sections only The charges, in his view, were the inevitable result of the policy which had been pursued since the introduction of the service Dr BARNETT STROSS pointed out that the cost of the service worked out at about £8 per head per annum He could not agree that that was too large a share of our national resources Mr MESSER thought the Bill undermined the principle of a completely free service He faced the future with foreboding, and he believed the sooner we could take the service out of the hands of the Treasury and finance it by other means the better He thought there was a possibility of this being done We should then be able to organise the service without always being faced with the fact that here was a ready pool from which the Chancellor could draw

Dr A D D BROUGHTON said everyone disliked the charges made in the Bill, but he thought they had been made necessary by the rapid development of the service He confessed that if he were edentulous, myopic, and tuberculous he would regard the eradication of tuberculosis as of more importance than the provision of dentures and spectacles

Colonel ELLIOT said that if we accepted that a ceiling must be put on the health service he did not see how we could escape from the logic that something must be done to implement that view It might well be possible to tackle the matter in another way, but at least the Bill got away from the idea that the service was sacrosanct and must not be touched

Mr MARQUAND thought the Bill provided distasteful machinery to accomplish a useful purpose But if these charges were not made, before long we should have to close hospital beds He could not agree with Dr Hill that the charges had been made in a slapdash manner The charges chosen would inflict less hardship than others consistent with making sufficiently large savings So far as possible they had tried to shield the sick, and to protect the poor they had empowered the National Assistance Board for the first time to give help to people in full-time employment He looked forward with some confidence to the possibility of a more peaceful world at the end of three years when our burdens would be lessened and we would be able to go forward to an improvement and expansion of our great National Health Service

QUESTION TIME

Hospital Group Management Committees

Lieut Commander RICHARD THOMPSON asked the Minister of Health how many persons had resigned from, or for other reasons ceased to serve on, hospital group management committees during 1950 —Mr MARQUAND replied 751 members of hospital management committees in England and Wales In answer to a further question he added that the number of seats on hospital management committees in England and Wales filled on March 31, 1951, was 6370, but the actual number of serving members was somewhat less, as many were members of more than one committee

Mr HAROLD SUTCLIFFE In view of these figures is not the number of resignations very high ? Mr MARQUAND The members are appointed normally for three years, 751 out of 6370 is not a high number

Hospital Waiting-lists

In answer to a question Mr MARQUAND stated that the number of people on hospital waiting lists in England and Wales on Dec 31, 1950, was 553,577

Hospital Service Reserve

In reply to Mr MESSER, Mr BLENKINSOP said that the number of recruits enrolled in the National Hospital Service Reserve was now 14,675 Since in the event of war the hospital and first aid services would need about 80,000 additional nurses he could not regard the present rate of progress as satisfactory

Sheffield Health Centre

Mr SOMERVILLE HASTINGS asked the Minister why the comprehensive health centre which the Sheffield Health Committee decided to inaugurate in 1948 by conversion of the Frith Park maternity and child welfare centre was not yet in operation , and what was holding up the anticipated progress —Mr MARQUAND replied I understand that the doctors concerned are now unwilling to coöperate

Mr HASTINGS Can the Minister use his good offices with these difficult doctors, so that at any rate we may have one health centre in operation as an experiment before long ? —Mr MARQUAND Nothing would please me better than that the doctors should coöperate, because approval for the centre was given quite a long time ago Mr HASTINGS Would the Minister consider calling a meeting of the difficult doctors ? It is not all the doctors in the neighbourhood who are involved Could he not arrange for a meeting of such doctors and put the case to them ?—Mr MARQUAND I would be very glad to look into that possibility

University of St Andrews

Replying to a question the Prime Minister announced that a royal commission has been set up

> ' To inquire into the organisation of University education in Dundee and its relationship with St Andrews University, and to recommend what changes, if any, should be made in the constitution, functions, and powers of the University of St Andrews of University College Dundee or of any other body or institution concerned "

Prof Dugald Baird, F R C O G , is the only doctor among the eight members named by Mr Attlee

Thames Pollution and Public Health

Mr J A BOYD CARPENTER asked the Minister of Health whether he was aware of the pollution of the River Thames , and whether, in view of the opening of the bathing season, he had any statement to make as to dangers to health involved in bathing in this river —Mr MARQUAND I am advised that above Teddington the risks to bathers are not great I understand from the Minister of Local Government and Planning that to purify the Thames completely would cost more money, materials, and labour than we can afford at present

Mr LIONEL HEALD In view of the very large number of people who bathe in the Thames, at places like Runnymede, for example, does not the Minister think that the expression he has used, that the danger is ' not great, might be put a little more specifically ?—Mr MARQUAND It is impossible to measure accurately the risk to health One can only give a general opinion based on that of my medical advisors

Sir RALPH GLYN asked the Minister of Health whether his attention had been drawn to the statement by the chairman of the Thames Conservancy that no instance had ever been reported, so far as the Thames was concerned, by any medical authority to the effect that the spread of poliomyelitis had been due to bathing in that river , and if he would consider the advisability of recommending the Medical Research Council, in conjunction with the Catchment and River Board Association, to go into the whole question of bacteriological pollution of rivers and lakes in the United Kingdom and the supposed effect bathing had in promoting this disease —Mr MARQUAND replied My medical advisers are in agreement with the statement mentioned The Medical Research Council are already engaged in an extensive investigation of poliomyelitis, in which I am assured that no field of inquiry as to possible causes will escape attention.

Sanitary Facilities in Prisons

Mr ANTHONY GREENWOOD asked the Home Secretary whether it was his intention to modernise the inadequate sanitation of the prisons —Mr CHUTER EDE replied Although the prisons in England and Wales are overcrowded, I do not accept the implication that the sanitary facilities in the prisons are in general inadequate for health and hygiene The existing facilities are being steadily brought up to modern standards, where necessary, but no radical change in the type of facilities provided is contemplated

Replying to a further question Mr EDE said the ablution facilities in the prisons in England and Wales were not ideal, but could hardly be described as inadequate Each prisoner had a water jug and wash basin in his cell with soap, brush, and towel he was allowed to have a hot bath, weekly, and the arrangements for washing in the workshops were being steadily improved.

Medicine and the Law

"Continuously under Care and Treatment"

WHEN the Herbert Act allowed a husband or wife to petition for divorce in England on the ground of incurable insanity, and again when in the following year a like remedy was given by the Divorce (Scotland) Act, it was emphasised that there would be grave difficulty in obtaining medical evidence that in a particular case the insanity was incurable The two statutes required the petitioner to show that the respondent spouse had been "continuously under care and treatment" for at least five years, the "care and treatment" being detention in accordance with an order made under the appropriate law governing mental treatment

In the recent case of F v F, reported in the *Times* (April 28), the probate Divorce and Admiralty Division has held that the word "continuously" means what it says The wife had been admitted to a mental hospital in England under a reception order in October, 1945 In December, 1946, the order was discharged and she was taken under escort to a mental hospital in Scotland where a sheriff's order was issued under the Lunacy (Scotland) Acts In March, 1948, she was brought back from Scotland to another mental hospital in England Though there might be little doubt that her condition was continuous, there had been the brief interval in December, 1946, before she was certified in Scotland, during that short space of time there was no certificate in existence There was also the similar break in March, 1948 The Commissioner accepted and applied the dictionary meaning of "continuous" as "uninterrupted," "conjoined without intervening space of time" He dismissed the petition on the ground that there were periods of time when the statute was not complied with.

The decision seems inevitable In Safford *v* Safford (1944), where the patient had been granted a total of 43 days' absence on trial for health under section 55 of the Lunacy Act, 1890 and a total of 59 days' absence on trial under section 275, it was held that there had been no interruption of the detention period Earlier in Benson *v* Benson (1941), where the wife had been discharged and was immediately transferred to another mental hospital as a voluntary patient, it was also held that there had been no interruption When the Herbert Act was passed, it unfortunately omitted to provide that detention in a Scottish mental hospital should count towards the five-year period In 1938 the Scottish Act expressly allowed detention in an English mental hospital to be so reckoned in Scotland And by the Law Reform (Miscellaneous Provisions) Act, 1949, it was enacted that detention under the appropriate statute in Scotland, Northern Ireland, the Isle of Man, or the Channel Islands might be taken into account in a petition in an English court But, as the recent decision shows, there must be no break in the "continuous" care and treatment

Notes and News

GENERAL MEDICAL COUNCIL

THE results of the voting in the recent election of eleven members of the council under the Medical Acts, 1886 and 1950, were as follows The names of the successful candidates are shown in capitals

ENGLAND	
JOHN THORNTON INGRAM M.D	16 253
REGINALD HUGH BALFOUR BARROW M.D	15 601
HARRY GUY DAIN M D	15 554
OCTAVIUS CYRIL CARTER, M.B	15 300
EDWARD ANDREW GREGG M.D	15 221
NOEL EVERARD WATERFIELD O B.E. F R.C.S	14 851
JAMES ALEXANDER BROWN M.D	14 669
Thomas Beaton O B.E M D	8834
WALES	
WILFRED VIVIAN HOWELL, M.B.	unopposed
SCOTLAND	
ROBERT WILLIAM CRAIG O B.E M.D	unopposed
IAN DINGWALL GRANT M.B.	unopposed
IRELAND	
FRANK KANE M.D	unopposed

The term of office of these members of the council is five years from April 30, 1951

TWO OF QUEEN ELIZABETH'S PHYSICIANS

Two physicians in ordinary to Queen Elizabeth were Walter Bailv or Bayley (c 1529–92), F.R.C.P (c 1581) fellow of New College regius professor of medicine in the University of Oxford, and later physician to the Queen, and his son in law Anthony Aylworth (c 1547–1619), also fellow of New College, who succeeded Bayley first as regius professor (1582–97) and later as royal physician They were both buried in the antechapel of New College, where the brasses on their graves are still remarkably well preserved, each including a portrait of the subject In 1904 exceptionally fine rubbings of these brasses were made for Mr L G H. Horton Smith, and he had photographs of these rubbings, endorsed with relevant details mounted and framed He has now presented the rubbings and photographs to the Royal College of Physicians

SOCIETY OF CHIROPODISTS

THE annual convention of the Society of Chiropodists was marked this year by the fulfilment of a long-cherished ambition. Opening the three-day convention at Friends House, London on April 26 Sir Henry Cohen, president of the British Medical Association said that the report of the Committee on Medical Auxiliaries had assured the chiropodists of professional status, the goal for which they had long striven. It must have given the society especial satisfaction to learn that it was the only organisation whose examinations the committee recognised as adequate for chiropodists wishing to work in the National Health Service He was glad, he said that the president of the B.M.A. had been invited to open the convention because it was the B.M.A. which had been instrumental in setting up the Board of Registration of Medical Auxiliaries and this had been the first formal step in the emergence of chiropody as a profession in its own right

Later that day, at a dinner held at the Park Lane Hotel London, Mr H Osmond Clarke, proposing the health of the society congratulated the chiropodists on attaining the dignity of a profession. It was well deserved he said, for chiropody was an important part of the medical service and no orthopædic unit was complete without a chiropodist The new advance added Mr Osmond Clarke, was of particular pleasure to him, for he had been associated with the society for many years and on occasions had been privileged to lecture at the Manchester School of Chiropody Replying to the toast Mr J H Hanby, the president, said that the society had every reason to be happy at this time, for the Cope report could be described as a judgment on its struggle for recognition. From its earliest days the society had tried to adopt a high standard of ethics and education taking the medical profession as its example It had been helped to reach this standard by the wisdom and guidance of eminent doctors many of whom were present The society, he said, realised the great responsibilities that accrued from the report but it would not flinch from them. The health of The Medical Profession was proposed by the Dean of St. Paul's, and Lord Webb-Johnson replied

HISTORY OF PHARMACY EXHIBITION

As a contribution to the Festival of Britain, the Wellcome Research Institution (183–193, Euston Road, N W 1) has arranged an exhibition to illustrate the history of pharmacy from the earliest times to the birth of chemotherapy The exhibition, which was opened by Sir Howard Florey, F.R S , on May 8, includes many rare books, prints, containers, and appliances The printed works on show include the earliest books on materia medica by Greek writers, an $11^1/_2$ ft mediæval scroll bearing a pictorial recipe for the Philosopher's Stone, the early herbals, and the first edition of the *Pharmacopœia Londinensis*, and trace the evolution of alchemy to pharmacy and chemistry Drug containers range from the kohl jar of Queen Hatshepsut (1500 B C) to the medicine chests of Lord Nelson and George Washington, and include some outstanding examples of the ceramic art Other sections illustrate the fundamental discoveries of chemistry and chemotherapy, the early apparatus used in anæsthesia, and the development of drug manufacture The exhibition is beautifully arranged and many of the exhibits, apart from their historical interest, are notable as works of art

THE HANDICAPPED CHILD

THE two month team training course on the reablement of physically handicapped children, which we announced on March 3, was attended by 49 fellows from seven European countries Planned to let experts from war devastated countries see something of modern technique in this particular field, it was financed by the World Health Organisation, the United Nations Department of Social Affairs, and UNICEF, organised by the Ministries of Health and Education, and administered by the British Council The syllabus was prepared by Dr Harold Balme, joint consultant on rehabilitation to the three sponsoring organisations and the Ministry of Health, who presided at most of the joint sessions, and the medical lecturers included Sir Allen Daley, Dr Wilfrid Sheldon Dr C D S Agassiz, Dr F S Cooksey, and Dr Evelyn Lucas

In the first fortnight an attempt was made, by lectures, visits and demonstrations, to present the complete picture of the modern treatment, reablement, education, vocational training, and employment of physically handicapped children Four weeks were devoted to intensive technical training, the teams being broken up into groups according to their various specialties and planted out in appropriate institutions During this period the detailed arrangements were undertaken for the orthopædic surgeons by Sir Harry Platt, for the physiotherapists by Dr Cooksey, and for occupational therapists, teachers, and social workers by Miss Lindsay and Miss Hope Murray, while representatives of the Ministry of Labour helped to plan the programmes for the vocational training instructors A tour by motor coach in the seventh week enabled the visitors to see something of the larger industrial centres, and to go to institutions in Leeds, Wakefield, Manchester, Oswestry, Malmesbury, and Oxford The final week was given to reports from the fellows themselves, who discussed the problems of their own countries and the points that had impressed them in the British approach

The success of the course should encourage similar undertakings in the future

"THE SNAKE PIT" AND THE PENDULUM

FOR those with friends or kin in mental hospitals *The Snake Pit* was doubtless a terrifying film, heightening the dread of mental illness, giving colour to stories of rough handling and callous methods of treatment, and doing nothing to lift the dark shadow which has for so long hung over hospitals for the insane It had many important qualities it showed that the mentally sick are capable of recovery, and that they can be successfully treated , and it was very good cinema, holding the attention by fine acting, clever photography, and skilful presentation But many have felt that the picture it gave of some kinds of American institution—whether accurate or not—could only serve to prejudice the work of our own mental hospitals, which are very different

In *Out of True*, described as ' the answer to *The Snake Pit*," British mental hospital care is presented in the familiar manner of the documentary , and it would be pleasant to be able to say that the results are therefore more convincing Unfortunately the pendulum has been allowed to swing too far the other way True the film opens well with the sick wife dreaming she has murdered her mother in law, and waking up to throw herself off Hammersmith Bridge , but once she is inside the hospital no painful episode of any kind is allowed to ruffle the peace of the onlooker All the other patients seem to be on the eve of discharge, treatment is so various and thorough that it is positively non stop, and doctors and nurses have a saintly wisdom which all of us may envy but few of us achieve

It would be unfair to say that the picture is false on the contrary, every incident, every scene, every bit of equipment is accurate , the photography is good, the dialogue sparing But so much is left out that the result is far from lively Good acting might have breathed a little life into it, but though Jane Hylton looks nice, and even worried at times, her hair remains curly and shining throughout, and she is too well bred for her circumstances—among which are two pleasantly cockney little boys It is doubtful whether this valiant effort on the part of the Crown Film Unit will erase from the minds of the public the impression made by *The Snake Pit*

University of Oxford

In a congregation held on April 26 the following degrees were conferred

D M—Q J G Hobson, P C Reynell
B M—Marie L S Beesley D L Hadley

Dr R A Chambers has been elected to a Radcliffe travelling fellowship at University College

University of Cambridge

Prof J D Boyd has been appointed to the chair of anatomy in succession to Prof H A Harris, who retires on Oct 1

Dr Boyd who is 43 years of age was educated at the Royal Belfast Academical Institution and at Queen's University, Belfast, where he graduated B SC in 1927 with first-class honours and M B with honours three years later After holding a Rockefeller fellowship at Johns Hopkins Hospital he was appointed lecturer in anatomy at Cambridge in 1935, and he held this post till he took up his present chair at the London Hospital His published work includes papers on the development of the upper lip and the carotid body

Prof R A Peters, F R S , has been elected to an honorary fellowship of Gonville and Caius College

On April 28 the following degrees were conferred

M D—D A W Edwards M E Moore C N Pulvertaft O L Wade I G Wickes
M Chir—J F R Withycombe
M B B Chir—*G S Brindley *P E Huddy

* By proxy

University of Edinburgh

The Cameron prize for 1951 has been awarded to Prof Tadeus Reichstein and Prof E C Kendall in recognition of their researches leading to the discovery of ' Cortisone '

University of Glasgow

On April 28, 1951, the degree of M D was conferred on Robert Paul (with commendation), D C Watt, and T S Wilson

University of New Zealand

Dr Gerald Smyth, consulting gynæcological surgeon to Johannesburg Hospital, has been appointed to the postgraduate chair of obstetrics and gynæcology at Auckland University College He will also be medical director of the obstetrics and gynæcology unit at Cornwall Hospital in Auckland, as well as director of the new Auckland women s hospital when it is built

Dr Smyth, who is 47 graduated M B at Trinity College Dublin. He was elected F R C P I in 1931 and F R.C O G in 1947

Rheumatism Research Fellowship

The University of Leeds in association with the Leeds Regional Hospital Board invite applications for a research fellowship in the surgery of rheumatism at a nominal salary of £1000 to £1300 Further particulars will be found in our advertisement columns

Royal Cancer Hospital Centenary

The hospital will be open between Tuesday and Friday, May 15 and 18, for visitors to outpatient clinics, operations, and radiotherapy sessions and the Chester Beatty Research Institute will be open to visitors on Wednesday, May 16, from 7 P M to 9 P M , and on Thursday, May 17, from 10 A.M to 6 P M when a series of demonstrations will be presented Further details may be had from the house governor of the hospital, Fulham Road London S W 3

International Scientific Film Congress

The fourth of these congresses is to be held in the Municipal Museum, the Hague, from Sept 15 to 22 Further information may be had from the secretary of the Scientific Film Association, 4, Great Russell Street London, W C 1

London County Medical Society

A clinical meeting of this society will be held at St Ebba's Hospital Epsom, on Tuesday, June 5, at 3 P.M. Further information may be had from Dr A. Kahan, the hon. secretary, St James Hospital Ouseley Road, Balham, S W 12

Casualties in Korea

Recent casualty lists contain the names of the following R.A.M.C officers

Wounded —Captain THOMAS DUNGAVEL, M.B. Glasg

Missing —Captain R P HICKEY M.B. Lond. Captain D R. PATCHETT, M.R.C.S.

Hospital Mattresses

The British Standards Institution has published two draft standards for hospital mattresses as follows (1) bordered mattresses (CN[M]572), and (2) spring interior mattresses (CN[M]571) Comments should reach the institution, 24/28, Victoria Street, London, S W 1 before June 19

Toxic Chemicals in Agriculture

Under this title the working party set up by the Minister of Agriculture and Fisheries under the chairmanship of Prof S Zuckerman, M.D F.R.S, has issued its report (H.M. Stationery Office Pp 16 1*s*) We referred to this committee's work in our issue of March 31 (p 728)

Scottish Society of Anæsthetists

This society held its annual meeting at Dunblane Perthshire between April 27 and 29 Dr H. H Pinkerton (Glasgow) the president delivered an address on General Anæsthesia for Collapse Therapy in Pulmonary Tuberculosis Dr T J C MacDonald (Aberdeen) was elected vice president. Dr W W Mushin (Cardiff) was a guest of the society, and gave a short talk which he entitled the Null Hypothesis. The prize which the society is awarding annually for the best paper submitted from a registrar was won this year by Dr J G Robson (Glasgow)

Sickness Benefit for Contacts

Under National Insurance regulations a person who has been in contact with an infectious disease can be treated as incapable of work for the purposes of claiming sickness benefit only if he is excluded from work on the certificate of a medical officer of health The Ministry of National Insurance states that such a patient who asks his doctor for a certificate should be advised to apply at once to the M.O.H. If under these circumstances, a patient claims sickness benefit on a certificate signed by his own doctor the local National Insurance office will in order to avoid delay send the relevant particulars to the M.O.H. asking him whether he will consider issuing the necessary certificate The patient's own doctor and the patient himself will be informed

New Maternity Wing at Hackney

On May 2 the Duchess of Gloucester opened a new maternity wing at Hackney Hospital, London. This wing was originally planned in 1937 but work was suspended in 1940 after the main structure had been completed. When building was resumed in 1949 the original plan for 86 beds was superseded by one for 109 beds. The building is constructed of brickwork on a steel frame with reinforced concrete floors The ground floor contains 3 single 1 two bed and 6 four bed rooms nursery room, lecture-room, waiting room, and office the first floor 7 single, 1 two-bed, and 6 four bed rooms, and nursery room the second floor 4 single 1 two-bed, and 6 four bed rooms, premature babies unit and nursery room the third floor (west wing) delivery section of 4 delivery rooms delivery and operating room, 3 first-stage rooms (2 single and 1 three-bed) and 1 single bed room for eclampsia cases, and the third floor (south wing) 4 four bed rooms for antenatal cases 1 day room with balcony solarium, examination room and doctors room. The staircase and lift are centrally placed and there is an external staircase at the end of each wing Each floor has a solarium, provided with radiant heat. The building is heated by steam and hot water with automatic temperature control in those rooms where a constant temperature is important

Fatal Shock from Television Set

At an inquest on a boy of 4 years, who died while watching television at his home in Leicestershire on May 3, the jury returned a verdict of accidental death, with a rider that there might have been more insulation on the set (*Times*, May 8) The boy, who was lying on the hearthrug with his older sister, appeared to have put his face against the metal loud speaker grille when his foot was on the fender, a radio expert found that owing to a defect in the loud speaker securing bolts the grille was in direct contact with the mains

British Society for Research on Ageing

The annual conference of this society will be held on June 2 at 3 P.M., at the medical school of the Middlesex Hospital, London, W 1 The following are to speak Dr Lester M. Morrison, of Los Angeles, on the Dietary and Medicinal Treatment of Atherosclerosis Prof R E Tunbridge, F.R.C.P, Process of Ageing in Connective Tissues Mr V Korenchevsky D.SC, Rôle of Deficiency of Sex Hormones in the Processes of Ageing, and Hormonal Treatment of Senescence in Male Rats Mr D C Hardwick B.SC, Histamine Metabolism and Ageing Dr E Geiringer Mechanism of Coronary Thrombosis

Police Surgeons Association of Great Britain

Police surgeons from all over Great Britain met on May 2 at New Scotland Yard to form a new association to be known as the Police Surgeons Association of Great Britain. The meeting was convened by the Metropolitan Police Surgeons Association, which was wound up on forming the new body Dr W G Johnston, president of the Metropolitan association, said that already 250 of the 1000 police surgeons in the country had applied for membership of the new organisation, a response which exceeded all expectations. The Metropolitan association had been of great value in improving conditions and amenities for its members and the new organisation would be even more successful for it would provide effective representation of all the police surgeons in the country Its aims would be first to improve and standardise conditions and rates of remuneration, and later to press for the establishment of a postgraduate diploma in forensic medicine for those engaged in police work. The need for this diploma was becoming greater since forensic medicine as a subject was slowly disappearing from the student's curriculum and from the final examinations

Dr W G Johnston was elected president of the new association, Dr R D Summers secretary, and Dr C J Berkeley Way treasurer

Fourth World Health Assembly

Seventy six member nations and territories were invited to send representatives to W.H.O's fourth World Health Assembly which opened in Geneva last Monday Three further nations—Japan, Spain, and the West German Federal Republic—whose claim for full membership will be examined by the assembly are also represented. Among the agenda are the adoption of international sanitary regulations which are intended to replace the existing sanitary conventions technical discussions on the education and training of medical and public health personnel and consideration of the director general's proposal for a 1952 budget of $8,700 000 (about $2 million more than the current budget) Prof René Sand, of Brussels is to receive the Leon Bernard prize

The United Kingdom delegates and advisers are

Ministry of Health.—Sir John Charles, F.R.C.P Dr Melville Mackenzie Mr W H Boucher Miss E Cockayne S.R.N and Mr F A. Mells

Department of Health for Scotland.—Sir Andrew Davidson M.D

Colonial Office.—Dr Wilson Rae.

General Register Office —Mr George North LL.D Dr W P D Logan, and Mr A E Joll

Dr Melville Mackenzie will also attend a meeting of the executive board of the World Health Organisation which will follow the World Health Assembly

---

The Dentists Register 1951, published at 15*s* by Constable & Co Ltd. 10, Orange Street Leicester Square, London W C 2 for the Dental Board, contains 15 327 names of dentists (including 122 dentists from the Dominions and Colonies and 277 foreign dentists) as against 15,052 (including 72 dentists from the Dominions and Colonies and 268 foreign dentists) in 1950

DISTURBANCE OF THE PUPILLARY REACTIONS*

J. H. DOGGART
M.A., M.D. Camb., F.R.C.S.
SURGEON, MOORFIELDS, WESTMINSTER, AND CENTRAL EYE HOSPITAL, LONDON

NOT only in the realm of pharmacological experiment, but also in everyday clinical practice, there has assuredly been a great change in our conception of the pupillary reactions. Reference to the textbooks of forty or fifty years ago will confirm something vividly remembered by many a clinician alive today—i.e., the dogmatic interpretation of pupillary phenomena, contrasted with the diffident attitude of modern teachers. A man exhibiting loss of the light reflex in one or both pupils stood less chance of being accepted for life assurance without "loading" of his policy than he would stand nowadays, when most candidates for medical diplomas can reel off a list of non-syphilitic reasons for that abnormality.

The semeiology of the pupil in the realm of head injury was almost as cogent as were the *sortes biblicæ* in ethical problems. Such-and-such manifestations in the pupil were the signal for trepanning, because their meaning was all too clear. The situation is different now. Modern developments in cranial surgery, linked with knowledge derived from necropsy findings, pathological histology, radiography, and other technical advances, have shown that many of the old clinical rules were fallacious through over-simplification. "The exception proves the rule," says the old proverb. "Yes," one might reply, "and so does a *pinch* of salt improve a plate of soup; but *too many* exceptions will wreck the rule, just as too many cooks *or* a surfeit of salt will spoil the broth."

CLINICAL EXAMINATION

Let it not be supposed, however, that pupillary signs have lost their importance. When we consider the extent of the nerve paths dealing with modifications in the size of the pupil, and if we also bear in mind the number and variety of important structures with which those nerve paths enter into relation, the absurdity of neglecting pupillary changes must be self-evident; but their significance cannot be properly assessed if it is expressed as a set of rigid rules. Abnormal pupillary reactions, if they are to help in building up diagnosis and prognosis, must be considered in relation to (*a*) the associated ocular signs, and (*b*) the remainder of the clinical evidence.

Routine examination of the eye will in a large proportion of cases supply the explanation for unilateral and bilateral abnormality of the pupil. Thus we may find that the iris sphincter has been ruptured by trauma, or that adhesions have been established between the iris and the cornea or lens. Ophthalmoscopy may reveal optic atrophy, or macular disease or other important lesions of the fundi and media. Instances could easily be multiplied, but the essential thing to remember is that ingenious but mistaken neurological reasons for a given pupillary disturbance have often been adduced when the real cause lay open to inspection in the eye itself.

In assembling the remainder of the clinical evidence we should pay special attention to the history, and try to ascertain what parts of the pupillary pathways have suffered. Impulses may be abolished altogether, or intensified, or in some cases may show wider fluctuation than is consistent with health. The relevant nerve paths may be severed, irritated, or stretched, or perhaps subjected to pressure by extravasated fluid, neoplastic masses, or displaced bone. Horner's syndrome, which results from abolition of the impulses from the right or left cervical sympathetic nerve, is an excellent instance of variety in causation. These associated signs of miosis, slight ptosis, and enophthalmia can be occasioned by birth injury, intracranial lesions, retropharyngeal abscess, cervical rib, or apical tuberculosis—to mention only a few of the possible causes. Claude Bernard's syndrome, which is the converse of Horner's, is a well-known feature of thyrotoxicosis, but can also arise from a multitude of different lesions in the thorax, neck, or elsewhere.

CHANGES WITH AGE

Some of the pupillary reflexes are known to exist in the sixth month of fœtal life. The psychosensory reflex is absent at birth but appears within a few days, by which time the reactions of maturity are already evident. External stimuli—e.g., light, near objects, and sensory impressions on the eyelids or the cornea—nearly always impel constriction, whereas internal changes—e.g., fear, pain, and nausea—tend to dilate the pupil. Thus we may say that miosis in sleep is attributable to a dearth of psychological activity.

In old age the average size and activity of the pupil are alike diminished by reason of atrophic changes in the iris musculature, hyaline degeneration of the stroma, and perhaps partial calcification of the iris vessels. The moment of death is marked by sudden opening of the pupil, and people used to regard this as the window through which the soul was wafted away from the body. Progressive contraction occurs with the onset of rigor mortis, but it has been observed that eserine, atropine, and various other drugs continue to act on the pupil until an hour or more after death.

PUPILLARY MECHANISM

Mention of the part played by local vascular changes in the production of senile miosis recalls that Langworthy and Ortega (1943) look on the so-called dilator muscle as a negligible factor in pupillary reaction. According to them, sympathetic mydriasis can only be achieved through the medium of the iris vessels. These workers also criticise the former conception of two antagonistic systems governing the pupillary movements. The sympathetic fibres, they say, act in harmony with those of the parasympathetic system, the latter holding the main power but able to exert more sensitive regulation by reason of the permanent tonic background created by the dilator impulses.

Lowenstein (1940, 1946) has made detailed investigations into the pupillary mechanism with the aid of cinematographic apparatus. In this way he has been able to secure motion pictures in darkness as well as in light. The "dark" pictures were taken with infra-red filters whereby records could continue to be made without maintaining retinal stimulation. Analysis of his results indicates that a latent period of rather more than a fifth of a second follows the impingement of light upon the retina. The pupil's contraction can be resolved into a rapid primary phase succeeded by two slower phases. Cessation of stimulation by light ushers in another latent period of just over a fifth of a second, and then come the three phases of dilatation.

The main practical significance of Lowenstein's work lies in the hope of gaining detailed facts about the separate responsibility of the sympathetic and parasympathetic systems for a given pupillary abnormality. In some cases of anisocoria, for instance, the ordinary methods of clinical examination may fail to show which is the abnormal eye, and whether the sympathetic or the parasympathetic system is at fault; but Lowenstein claims that the rapid primary phase of contraction to light is entirely a parasympathetic phenomenon, whereas the secondary and tertiary phases depend on sympathetic activity. If stimulation by light is followed by an abnormally long latent period, and then by a contraction

Stephen —On May 2 in London George Mackie Stephen M A M B Aberd

Theobalds —On May 1 in London Owen le Mare Theobalds M R C S aged 90

Trapnell —On April 28 at Beckenham Kent, Francis Cyril Trapnell M D Camb

Wayte —On May 4 at Croydon, John Wayte M A B M Oxfd aged 89 sign is of grave import Suprageniculate lesions do not *directly* interfere with the pupillary reactions but may exert an indirect influence from hæmorrhage The question of multiple injury must always be considered before we venture to interpret the signs Thus, for instance, radiographic evidence and exact localisation of an intracranial foreign body cannot alone enable us to explain the signs, because the main havoc may be due to destruction along the path pursued by the missile on the way to its final lodgement

GENERAL ANÆSTHESIA

Psychosensory impulses are responsible for the wide-open pupils commonly seen during induction of anæsthesia, but soon the pupillary diameter reverts to normal, and the response to light is retained until narcosis has gone deeper than is usually safe in surgical operations Some patients are more susceptible than normal to the preoperative injection of atropine, hence a disproportionate degree of mydriasis may become evident Even so, the reaction to light is a valuable guide to the anæsthetist and is far preferable to the corneal reflex. The so-called "anæsthetic eye" is seldom due to the action of vapour, but rather to abrasion of the epithelium by fingers or gauze.

SPECIAL ABNORMALITIES

Argyll Robertson Pupil—The mistaken application of an Argyll Robertson label to every pupil which does not react to light but reacts to convergence is nowadays less common than it used to be, because the existence of a similar phenomenon in the tonic pupil has so often been emphasised of recent years The genuine Argyll Robertson pupil is small and does not dilate under the influence of atropine, though painful stimuli can still produce mydriasis The outline is seldom a regular circle, and is sometimes quadrilateral or elliptical. Another criterion laid down by Argyll Robertson purists is that the optic tracts must be healthy In other words they would withhold the Argyll Robertson label from all patients afflicted with serious defect of vision Loss of light reflex with retention of the reaction to convergence has been recorded in different diseases of the central nervous system—e g, disseminated sclerosis—and in injury to the base of the brain. The lesion responsible for an Argyll Robertson pupil is probably in the upper half of the mid brain near the aqueduct of Sylvius

Tonic pupils are commoner in women than in men, and often arise suddenly The third decade is the most likely time of onset, and the abnormality is unilateral in most cases Diminished tendon-jerks, especially of the ankle and knee, have often been noted, but this association is by no means invariable The affected pupil is usually larger than normal, and its variability in size contrasts strongly with the rigid miosis of an Argyll Robertson pupil. Irregularity of circumference is another typical feature, and the light reaction, direct and consensual, is absent or impaired Another point of difference from the Argyll Robertson pupil is the ready response to mydriatics but perhaps the most striking feature of all is the slowly progressive contraction of a tonic pupil on convergence, followed by even slower relaxation when the effort has been relinquished.

Paradoxical pupillary reactions offer a fascinating field for speculation It will be recalled that one of the cardinal elements of Horner's syndrome is miosis In some cases, however interruption of the cervical sympathetic has been followed by temporary mydriasis during mental excitement No certain explanation is known but it has been suggested that the dilator muscle is more susceptible to the action of adrenaline after deprivation of its nerve supply Reflex mydriasis under stimulation by light, and a similar response to convergence, have also been described.

Rare abnormalities of the pupil occur in endless variety Thus cases are on record in which rhythmical contraction and dilatation occurred synchronously with the excursions of *nystagmus* Well-marked *ectopia*, especially in an upward and inward direction, has more than once been noted in association with neoplasms of the pineal gland or of the third ventricle The gift of *voluntary mydriasis* must be at least as common as voluntary nystagmus, and I used to know a Belgian lady whose chief device of allurement was deliberate *hippus* When she gazed at you, with her pupils collapsing and expanding like a pair of concertinas, it was time to think of other things. One last abnormality can be mentioned In *cog-wheel pupil* the diameter waxes and wanes in a series of jerks instead of describing a continuous sweep

GENERAL CONCLUSIONS

Pupillary reactions in health and disease provide rich material for the anatomist, pharmacologist, and clinician alike Subject to innumerable congenital malformations as well as daily fluctuations in size, liable to be modified by age, and susceptible to the effect of drugs, injury, and disease, the pupils may be likened to a pair of mirrors in which strange events can be viewed with varying shades of distinctness, so long as they are considered in relation to the images emanating from other sources, but mirrors artificially isolated will cloud the issue and lead us into distortion, like the mirrors that adorn the walls of a fun fair

THE USE OF THE PHONOCARDIOGRAPH IN CLINICAL MEDICINE*

WILLIAM EVANS
M.D, D.Sc Lond, F.R C.P
PHYSICIAN TO THE CARDIAC DEPARTMENT OF THE LONDON HOSPITAL, AND TO THE NATIONAL HEART HOSPITAL,
CONSULTING CARDIOLOGIST TO THE ROYAL NAVY

RECORDING the heart sounds and murmurs is not a new science, the practice is as old as electrocardiography The characteristic electrocardiographic patterns in the several forms of heart disease are familiar to us, and it is timely to examine in what manner the phonocardiogram helps in the diagnosis of cardiovascular disorders Mention should be made of a handicap which no longer applies to the electrocardiogram—i.e, that standardisation of the sound record has not yet been wholly achieved, but this drawback has not hindered materially the contribution already made by the test to the interpretation of auscultatory signs, nor is the advent of this desirable standardisation of records to be long delayed.

I intend here to recount the ways in which the phonocardiograph has already helped, to name the circumstances in which the tracing is a necessary test, and to suggest what part it can play in the solution of outstanding problems

WHAT PHONOCARDIOGRAPHY HAS ALREADY ACCOMPLISHED

It should never be the purpose of phonocardiography to bring to light heart sounds or murmurs which do not yield to auscultation, its function is to show where these lie in relation to the separate phases of the cardiac cycle, and their exact incidence in the different parts of systole or diastole In this work of precise allocation of heart sounds and murmurs the test has enabled the clinician exclusively effected by the primary phase, Lowenstein concludes that the sympathetic system is disturbed He calls this type of response the tonohaptic reaction, and has noted its association with catatonia, postencephalitic parkinsonism, Frohlich's syndrome, and other disorders

---

* Based on a communication made to the International Congress of Physicians in London, 1947

PHARMACODYNAMIC TESTS

Without attempting any detailed review of Lowenstein's work, we can hope that it will facilitate differential diagnosis in many obscure disorders of the central nervous system, especially if the apparatus of investigation can be simplified Meanwhile a cruder method of differentiating sympathetic from parasympathetic abnormality exists in the pharmacodynamic tests, which depend on the fact that some drugs stimulate, and some depress, the parasympathetic-system, whereas its rival is stimulated by other drugs—e g, cocaine By noting the responses made to different drugs, we can, for instance, usually differentiate spastic from paralytic mydriasis

MODIFICATIONS IN DISEASE

Pupillary abnormality can be classified in different ways, and no attempt will here be made to set up a comprehensive system One of the obvious plans is to separate anomalies into static and dynamic, and that distinction is in some respects convenient, but of course the healthy pupil, and many types of unhealthy pupil, may show considerable fluctuation throughout our examination Moreover there will be numerous instances of static abnormality in which the reactions are also abnormal To take the simplest possible example, a pupil anchored by ring posterior synechia might be smaller than normal, but would also betray dynamic abnormality in the negative sense of failing to respond to stimuli

Experienced clinicians can observe at a glance whether the diameter of a pupil departs unduly from the average of about 3 5 mm, and whether there is any *important* difference between the two sides The word "important" is emphasised because chance congenital discrepancy between the innervation, musculature, or stromal architecture of the two irides is the likeliest explanation in many cases of *small* difference—say, not more than 0 5 mm

Other features to be surveyed in each pupil are the shape and degree of regularity of its circumference Any associated atrophy or irregularity of the iris stroma should also be noted, and there are various other items more interesting to the ophthalmologist than to the physician Obvious examples are the pigment frill at the rim of the pupil, the presence of persistent pupillary membrane or epicapsular stars, and the state of the lens fibres, in so far as the latter can be ascertained on preliminary scrutiny with the aid of a loupe

Simple routine inspection without an array of pupillometric devices will often supply not only facts of importance but also guidance as to what other special items of information should be sought The response of each pupil to light, direct and consensual, and to convergence must also be ascertained It has now been shown that the efferent nervous pathway for constriction of the pupil on convergence is not necessarily the same as that which subserves the response to stimulation by light We know that the innervation of the eye and its adnexa is subject to considerable variations, as indeed may happen elsewhere in the body, and it may well be that in many people the two pathways coincide throughout In some people, however, it has been possible to prove that the constrictor impulses derived from convergence are relayed by cells other than those of the ciliary ganglion

Here it seems appropriate to mention that universal agreement has not yet been reached about the relative efficacy of accommodation and convergence in provoking miosis It will be remembered that, where the older clinicians spoke of the pupils reacting to accommodation, their successors tend to speak of a convergence reaction, and indeed it seems clear that convergence is at any rate the major force Those who insist on attributing to accommodation *at least a share* in the pupillary constriction are apt to enlarge on instances in which focusing still provokes miosis after abolition of the power to converge, but their opponents retort that, even after manifest convergence has been rendered impossible, it is necessary to allow for *latent* convergence, in the nervous impulses which would otherwise have approximated the two eyes, and that these impulses, not those of accommodation, are the effective constrictors

ANATOMICAL CONSIDERATIONS

All interpretations of the pupillary signs should be made in the light of up to date anatomical facts The Edinger Westphal nucleus, from which emerge the pupillo constrictor fibres, receives excitatory stimuli from the occipital and frontal regions of the cortex, but recent researches have shown that the frontal cortex also sends out inhibitory impulses In other words, mydriasis formerly regarded as mediated by stimuli travelling from the frontal cortex to the sympathetic centre in the hypothalamus is really attributable to cortical inhibition exerted on the Edinger Westphal nucleus

Another important anatomical feature is the existence of an inhibitory sympathetic pathway from the hypothalamus to the constrictor centre, and it is abundantly proved that mydriasis accompanying powerful emotions is achieved not so much by stimulation of the sympathetic fibres as by inhibition of parasympathetic constricting nerves

One more anatomical fact should be emphasised The old teaching that the afferent pathway of the light reflex relayed in the superior colliculi had to be abandoned some years ago It is now generally agreed that, in man, the pupillary fibres leave the optic tracts before the lateral geniculate body is reached They pass by way of the brachium of the superior colliculus to reach the pretectal nucleus at the junction of the diencephalon and the tectum of the mid brain Most of the fibres cross in the posterior commissure, but some remain on the same side, with the result that fibres from each optic tract enter both Edinger Westphal nuclei Thus stimulation of the pretectal area induces bilateral pupillary constriction

PUPILLARY CHANGES IN HEAD INJURY

Routine inspection of the pupils will enable us in many cases to identify, and in others to suspect, lesions of the visual apparatus, and it may incidentally furnish early evidence about disease of the central nervous system In cases of head injury examination of the pupils may similarly convey information about the situation and extent of the damage, but a still more important reason for watching the pupil in such circumstances is to seek guidance about the need for operation Thus unilateral dilatation and immobility of one pupil rapidly supervening in a case which had at first displayed no pupillary abnormality should suggest ipsilateral intracranial hæmorrhage, and similar signs are likely to become manifest in the opposite pupil unless the flow is staunched The mechanism of this phenomenon is not known for certain, but pressure upon the parasympathetic centre in the mid brain is often blamed Others postulate traction on the nerve trunk by the tectorial pressure cone

Pontine hæmorrhage may provoke bilateral miosis, and severance of one optic nerve abolishes the direct response to light but leaves the consensual reaction unimpaired Bilateral mydriasis and inactivity is of no localising or prognostic value when it is noted in the immediate post traumatic stage, but persistence of this

Pulmonary Stenosis

When the systolic murmur of pulmonary stenosis is confined to the pulmonary area and is accompanied by a thrill, and the second heart sound is attenuated in the same area, the clinical diagnosis usually presents no difficulty, and the electrocardiogram of right heart preponderance is expected.

When a thrill is absent, the murmur not loud, and cyanosis present, Fallot's syndrome is the usual explanation.

When both thrill and cyanosis are absent, the differential diagnosis of an innocent murmur in this area from the murmur of slight pulmonary stenosis becomes difficult. It is here that a phonocardiogram may give valuable help. If the tracing shows a pansystolic murmur continuing almost up to, and even embracing the aortic moiety of the second heart sound, leaving a short silent gap in front of an attenuated pulmonary second sound, the presence of pulmonary stenosis is confirmed, but if the murmur is confined to mid systole it is innocent.

To substantiate these inferences made from a study of the phonocardiogram in patients in whom clinical examination was implemented by the electrocardiographic and radiological examination, observations need to be made in patients where cardiac and pulmonary artery catheterisation has been an additional test. Should this specific phonocardiogram be confirmed for the murmur of pulmonary stenosis and for the innocent murmur in the pulmonary area, investigation of such murmurs by cardiac catheterisation need not afterwards take place.

Ventricular Septal Defect

The innocent parasternal systolic murmur has already been described, and the phonocardiogram shows it to be a short high frequency murmur in mid systole. On the other hand, the murmur of ventricular septal defect, usually accompanied by a thrill, is a pansystolic murmur and is continued in strength up to the second heart sound. In this differential diagnosis, therefore, the phonocardiogram has become a valuable test, but it has yet to determine the relationship between the termination of the murmur and the aortic and pulmonary components of the second heart sound.

Splitting of Second Heart Sound

Splitting of the second heart sound in the pulmonary area is a common finding in health. If its threshold of audibility is high enough to allow it to be heard along a line joining the mitral area to the xiphisternum, bundle branch block or constrictive pericarditis is the usual cause, and rarely cardiac infarction.

CLINICAL PROBLEMS WHICH WILL YIELD TO PHONOCARDIOGRAPHY

Although opinion may be expressed even now on some of the problems discussed under this head, further investigation is needed before our knowledge of them is complete.

Since phonocardiography has been applied more often to test clinical auscultation in *hypertensive heart failure*, it has become clear that the triple rhythm is usually created by the addition of the third heart sound. When moderate tachycardia is present, as is often the case, the coincidence of the natural or intensified auricular sound with the added third heart sound will accentuate it (summation triple rhythm).

Mention has already been made of some cases of *hypertension without heart failure* where the auricular portion of the first heart sound is seen as a prominent wave in the phonocardiogram and when this is joined by the natural third heart sound on account of tachycardia a triple rhythm is initiated (innocent summation triple rhythm). Future work may give the reason for this accentuated auricular sound, which is a feature of only a few patients with hypertension. The two kinds of triple rhythm can be distinguished on clinical grounds, because the kind associated with hypertensive heart failure arises in a patient in whom a past history of nocturnal breathlessness (cardiac asthma) is always present.

When the phonocardiogram is recorded in patients with *mitral valve disease* (mitral stenosis) it will show one or more of three murmurs—presystolic, pansystolic, or mid diastolic. It is for future investigation to show how often these are found together or separately, and the circumstances that decide their presence. In the meantime it may be said that, since a mid diastolic murmur is a common finding in the phonocardiogram of mitral disease, it should encourage a careful search for this murmur during auscultation in a patient where a diagnosis of mitral disease is suspected on other grounds. It is also necessary to decide whether hearing a clear third heart sound is inimical to the diagnosis of mitral valve disease, and whether the sound in that event is invariably impure from an associated mid diastolic murmur.

So far the *innocence* or otherwise of a murmur on phonocardiographic grounds has been decided from its place in the cardiac cycle, but a determination of the frequency of the separate murmurs may also contribute to a readier recognition of the innocent ones from among others.

There are more problems which may yield to phonocardiography, and only allusion to some of them have been made. When most is known of its interpretation phonocardiography will come into common use, and it will have as its chief function the according of greater precision to the art of auscultation, and rendering unnecessary other more elaborate tests which impose unwarranted discomfort on a sick patient.

ACTION OF ASCORBIC ACID ON TUBERCULIN-SENSITIVITY IN GUINEAPIGS

AND ITS MODIFICATION BY DIETARY AND HORMONAL FACTORS

D A Long, M.D Lond
A A Miles, M.A. Camb, F R C P
W L M. Perry, M.D St And.

From the National Institute for Medical Research Mill Hill, London

In a previous paper (Long and Miles 1950), it was shown that adrenocorticotrophic hormone (A C T H) or 'Cortisone' given to a guineapig infected with B C G would diminish its sensitivity to tuberculin by a significant though limited, amount. In this paper we show that in the guineapig neither cortisone nor A C T.H has any direct effect on tuberculin allergy, their desensitising action depends on dietary factors.

As a routine, our sensitised guineapigs were maintained on a pelleted diet (Bruce and Parkes 1947). This diet is grossly deficient in ascorbic acid, which was provided in a supplement of unlimited raw cabbage. It was on such animals that we demonstrated the desensitisation by cortisone and A C T.H. In a subsequent attempt to determine the role of vitamin C in allergic hypersensitivity, we substituted in one experiment ascorbic acid, 20 mg by mouth three times a week, for the cabbage, and found that guineapigs maintained on this diet were apparently not desensitised by cortisone. In another experiment, sensitised guineapigs fed on pellets alone to tell the various forms of triple heart rhythm, enlisting this sign to help significantly in diagnosis, and has made easier the clinical recognition of an innocent heart murmur.

Clinical Classification of Triple Heart Rhythm

Since triple rhythm denominates the cadence produced when three heart sounds recur in successive cardiac cycles, the designation should not apply, for instance, to most cases of mitral stenosis, where the added noise is the mid diastolic murmur which begins at the third heart sound and converts it into a murmur. Cautious auscultation should distinguish splitting of heart sounds from triple rhythm, because split sounds are never separated sufficiently to produce the cadence so obvious when three separate sounds create a triple heart rhythm. The phonocardiogram has shown that there are only three kinds of triple rhythm, and the first is the only important one, the other two having most weight in differential diagnosis.

Triple Rhythm from Addition of Third Heart Sound.—This may be met with in healthy people, when it is common up to the age of 20 years, uncommon after 30, and not found after 40. It can be told from that met with in heart disease on clinical grounds, and among the distinguishing features the one needing greatest emphasis is the patient's age; for if triple rhythm from addition of the third heart sound is found after the age of 40, one of the following conditions should be sought in turn to account for it: hypertensive heart failure; cardiac infarction; pulmonary heart disease, including pulmonary embolism, emphysema, and primary pulmonary hypertension; heart failure from aortic stenosis or aortic incompetence; constrictive pericarditis; auricular septal defect; and familial cardiomegaly. In the case of the last three, splitting of the second sound is often the explanation of a casual auscultation which at first may have interpreted it as triple rhythm.

Triple Rhythm from Audible Auricular Sound.—Appreciable separation of the auricular and ventricular parts of the first heart sound as a result of delayed auriculo-ventricular conduction, with prolongation of the P–R period in the electrocardiogram to 0·25 sec. or longer, is the common cause of this kind of triple rhythm.

Occasionally in hypertension a special feature of the phonocardiogram is a conspicuous auricular portion of the first heart sound. In such cases the addition of tachycardia, either induced or occurring fortuitously, causes a coincidence of the accentuated auricular sound with the natural third heart sound and creates a triple heart rhythm (innocent summation triple rhythm).

Triple Rhythm from Added Sound in Late Systole.—Here the adventitious sound is placed nearer to the second than the first heart sound. It may be so close to the second as to simulate splitting of this sound, but it is seldom confused with triple rhythm caused by the addition of the third heart sound. This auscultatory sign is not common and it has no significance except in differential diagnosis.

Phonocardiogram of Innocent Heart Murmurs

When the examination of subjects exhibiting a murmur but no evidence of heart disease included a phonocardiogram, it was possible to assemble physical signs which permitted a clinical recognition of three common types of innocent heart murmurs audible in or near the mitral area. In all three kinds the tracing was distinctive, showing a relatively silent gap between the murmur and the first heart sound which precedes it and another between the murmur and the second heart sound which succeeds it.

Innocent Murmur of Reclining Posture.—This is blowing in character and is not loud; hence, it often disappears on deep inbreathing. It is louder in the reclining posture, when the mitral murmur is joined by one in the pulmonary area. It is common in young people and is never met with after the age of 40. The phonocardiogram shows the murmur in mid systole.

Innocent Murmur in Late Systole.—This murmur too, is blowing in character; it is loud and short, persisting on deep inbreathing; it is found at all ages. It occupies late systole and is nearer to the second than the first heart sound, and this feature is easily made out by auscultation; graphically the murmur ends short of the second sound. Rarely, a murmur apparently in late systole has been shown to arise from mitral valve disease, but in this event the phonocardiogram shows that, although the bulk of the murmur may occupy late systole, it starts as a less intense murmur as far back as the first heart sound, and therefore is not a murmur confined to late systole, as is the case with the innocent variety.

Innocent Parasternal Murmur.—This murmur is blowing in character and is loud enough to persist during deep inspiration. It is loudest in the fourth intercostal space at the left border of the sternum, but is never accompanied by a thrill. Although commoner in young people it is often found in older adults. The murmur occupies mid systole, and the phonocardiogram may be a valuable test in diagnosis, differentiating it from the pansystolic murmur of ventricular septal defect.

CLINICAL STATES REQUIRING A PHONOCARDIOGRAM FOR DIAGNOSIS

Mitral Valve Disease

When a thrill is found in the mitral area, or when presystolic or mid diastolic murmurs are audible, the diagnosis of mitral stenosis is not in doubt, but if a systolic murmur is the only outward sign, the clinical diagnosis of mitral valve disease gives rise to difficulties, which may include equivocal appearances on radiological examination. It is in this circumstance that a phonocardiogram is an indispensable test. If the murmur is the outcome of mitral valve disease, the tracing will show the murmur filling systole (pansystolic), and a mid diastolic murmur may also be evident.

Aortic Stenosis

Among newer information that has come to us about aortic stenosis is the appreciation that its systolic murmur, often without a thrill, is frequently louder *to the left* than to the right of the sternum. Thus is added another systolic murmur to the many found in the mitral area, and the phonocardiogram has proved valuable in distinguishing it from the others; Leatham (1947) and Levine and Harvey (1949) have described a distinctive pattern for it, where the main bulk of the murmur is in mid systole, sometimes starting a little late, and especially showing a silent gap between the murmur and the second heart sound.

Patent Ductus Arteriosus

Since the operation of ligature of a persistent ductus arteriosus has become commonplace, the clinician's responsibility in its diagnosis has increased. A characteristic continuous murmur must be demanded as well as a physiological electrocardiogram, but experience dictates that no patient should proceed to operation without a preliminary phonocardiogram which not only displays the continuity of the murmur throughout systole and diastole, but also shows accentuation of the murmur in late systole and particularly at the second heart sound in early diastole. Attention to the sound tracing will diminish the instances where an open ductus cannot be found at operation, and the test should become routine practice, especially where the murmur is not accompanied by a thrill.

ascorbic acid found in the full factorial analysis All but one combination of more than two factors, as would be expected, approach the significant level. The single exception—i e , cortisone + A C T H. + ascorbic acid—is not significant, owing to the exceptionally high variation between the responses of the five animals in this particular group It should be noted also that, when all four factors were given together, the sensitivity was diminished fourfold , and that this is a significantly greater change than that produced by ascorbic acid alone

The figure shows the mean responses to these isolated treatments The fitted slope of the common regression line has been made to pass through the mean of each treatment group This is permissible because the factorial analysis showed that there were no significant departures from a common regression and that the treatment dose interaction was not significant—i e , the slopes of all the lines may be considered to be linear and parallel. To simplify the interpretation, those groups in which A C T.H was given have been omitted from the graph because it is evident that A C.T.H. behaves in this respect like cortisone

Summarised Conclusions from the Analysis

The effects shown graphically in the figure are summarised in table III, experiment 1 Sensitivity is cited simply as high and low according to the position of the response line in group I or group II (see figure) From the results we infer that

1 Ascorbic acid diminishes tuberculin sensitivity, or, rather, maintains sensitivity at the low level (group *c*)

2 Cortisone and A.C T.H. have no action on the sensitivity of guineapigs fed on a diet deficient in ascorbic acid (group *b*)

3 Neither cortisone nor A.C T.H. separately increases the desensitising action of ascorbic acid (group *d*)

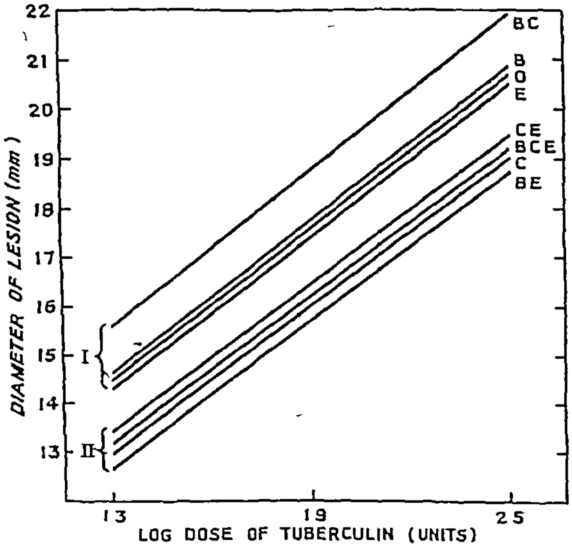
4 Cabbage, which contains ascorbic acid, does not diminish sensitivity (group *e*)

5 Cabbage inhibits the desensitising effect of excess ascorbic acid added to the diet (group *f*)

6 Both cortisone and A.C T.H. antagonise the anti-ascorbic acid effect of cabbage (groups *g* and *h*)

Cabbage Factor

We must therefore postulate in cabbage a factor which directly affects the metabolism of ascorbic acid, modifying its desensitising action , and, if we regard desensitisation as a natural function of tissue ascorbic acid, then cortisone and A C T.H affect sensitisation only by modifying this dietary derangement of ascorbic acid metabolism



Dose-responses to 20 80 and 320 i.u. of tuberculin in sensitive guineapigs with parallel regression lines fitted to mean diameters of lesions : B cabbage C, ascorbic acid ; E cortisone ; O controls.

TABLE III—EFFECT OF ASCORBIC ACID AND CABBAGE SUPPLEMENTS TO A BASAL DIET AND OF SINGLE INJECTIONS OF CORTISONE 2 MG AND GLUTATHIONE 100 MG ON TUBERCULIN HYPERSENSITIVITY OF B C G INFECTED GUINEAPIGS

Expt.	Group	Treatment	Tuberculin sensitivity
1	(*a*)	Basal diet	High*
	(*b*)	+ cortisone	High
	(*c*)	+ ascorbic acid†	Low*
	(*d*)	+ ascorbic acid and cortisone	Low
	(*e*)	+ cabbage†	High
	(*f*)	+ cabbage and ascorbic acid	High
	(*g*)	+ cabbage and cortisone	Low
	(*h*)	+ cabbage and ascorbic acid and cortisone	Low
2		Basal diet	
	(*k*)	+ ascorbic acid‡	Low
	(*l*)	+ ascorbic acid and glutathione‡	High
	(*m*)	+ cabbage and cortisone	Low
	(*n*)	+ cabbage and cortisone and glutathione	High

* For definition see text † In the diet
‡ A single intraperitoneal injection

The nature of the cabbage factor must be determined by direct fractionation of active extracts But in this connection it is worth noting the observation of Schultze et al. (1938) that acid-insoluble SH compounds, as well as glutathione, inhibited the oxidation of ascorbic acid by a preparation of liver cells An SH compound is found in the seeds and roots of certain vegetable foods, including the brassicæ (Astwood et al. 1949), and it is probable that similar substances are present in extracts of cabbage leaves (Greer and Astwood 1948), because both have antithyroid activity Such substances, if absorbed from the alimentary tract, might diminish the tissue reactions of ascorbic acid associated with desensitisation We found (table III, experiment 2) that, in guineapigs fed on a diet deficient in ascorbic acid, 100 mg of glutathione in the reduced state, given intraperitoneally 6 hours before the tuberculin injections, inhibited the desensitising action of 100 mg of ascorbic acid injected intraperitoneally (table III, *k* and *l*) , and a similar dose of glutathione had the same effect in cabbage fed guineapigs in which the cabbage factor was antagonised by cortisone (table III, *m* and *n*)

DISCUSSION

The relation we have found between ascorbic acid, a cabbage factor, and cortisone or A C T H may of course be peculiar to the allergic guineapig Other animals may react differently For example, in rabbits on the same pelleted diet but receiving no cabbage, our colleague Dr J H Humphrey (personal communication) finds that the Arthus reactivity is greatly diminished by a single injection of cortisone In these rabbits, which do not depend on diet for their ascorbic acid, the vitamin was presumably present in tissues, and could not have been antagonised by a cabbage factor Nevertheless, the guineapig resembles man in needing dietary ascorbic acid, and may also be closely analogous in allergic reactivity

Since we were able to modify the allergic state only between two well defined limits, embracing at the most a four- to five fold change in hypersensitivity, the extrapolation of our findings to cover the whole range of hypersensitivity in the guineapig is probably not justifiable We might have effected a greater change had we used a basal diet free from ascorbic acid Nevertheless within these limits we are confident that the changes from high to low, and from low to high, sensitivity are real. We are less certain that the guineapigs under various treatments assigned to either the high or the low groups had essentially the same sensitivity The variability of the responses in five guineapigs is relatively large, and with more guinea-until they became moderately deficient in ascorbic acid (cf Long 1950) were more sensitive than those fed on pellets and ascorbic acid It is difficult to correlate the results obtained in different experiments, because of the great variation in the mean responses of different groups of sensitised guineapigs to tuberculin We accordingly devised a factorial experiment with guineapigs maintained on pellet diet alone, to explore the relations of cortisone, ACTH, cabbage, and ascorbic acid in their action on tuberculin sensitivity

METHODS

The design of the experiment is evident in the first column of table I, where the 15 combinations of treatment with the four substances are listed Five albino guineapigs, weighing about 350 g, were used for each combination, and a 16th group of five served as a control All the animals were given 2 mg wet weight of BCG in the right adductor muscles, and were tuberculin tested 28 days later by the multiple dose method (Long and Miles 1950) During this 4 week period unlimited cabbage, and 20 mg of ascorbic acid by mouth three times a week, were given to the appropriate groups In cabbage fed animals desensitisation with cortisone was greatest when a single dose was given subcutaneously 6 hours before the tuberculin injections, given at this time its effect was maximal with 5 mg per kg of body weight and scarcely detectable with 0 2 mg per kg In the experiments, therefore, we used a dose of 2 mg in the 350 g guineapigs 6 hours before the tuberculin One international unit of ACTH (equivalent to 1 mg of Messrs Armour's La 1 A standard) was given subcutaneously $2^1/_2$ hours before the tuberculin injection

As in our previous work, the diameter of the 24 hour tuberculin lesions was proportional to the logarithm of the dose of tuberculin, and the degree of sensitivity could be estimated by the relative positions of the dose response lines fitted to mean lesion diameters plotted against log dose, as in the accompanying figure

RESULTS

Full Analysis

It is clear from the figure that the response lines tend to cluster into two groups In group I, exemplified by the animals on pellet diet alone (control), the sensitivity is relatively high, in group II it is relatively low Moreover, although within each group there are differences in response, yet only one of these differences on analysis proved to be significant On the other hand, all the responses in group II differed significantly from those in group I That is, we were unable to diminish the sensitivity of the controls by more than a limited amount, corresponding to a three- to four fold change in tuberculin reactivity, and this maximum effect was produced, in guineapigs on a diet deficient in ascorbic acid, by treatment with ascorbic acid alone

(Controls)	(1 000)		

Each figure in column 2 represents the dose of tuberculin required to produce a lesion of a given diameter in the treatment group, the corresponding dose in the control group being taken as unity Thus in the first group listed, about twice as much tuberculin was required—i e the animals were half as allergic as the controls.

* Significant effect † Effect approaching significance

Complete analysis of the experiment (table I) leads to the following conclusions

(1) Ascorbic acid produces a significant effect

(2) Cortisone produces a significant effect

(3) Ascorbic acid, since it produces an effect alone, has no significant interaction with cortisone or with ACTH, but the interaction between cabbage and ascorbic acid is significant

(4) Cabbage, which alone has no effect, has a significant interaction with both ACTH. and cortisone

It is apparent, therefore, that there is a complex relationship between cortisone and ACTH on the one hand, and cabbage and ascorbic acid on the other, further information about the nature of this relationship is obtained by comparison of the direct effects of the individual treatments with those in the controls These direct comparisons are shown in table II Since they are made with groups of five animals only, the advantage of the factorial design, which enables the comparisons of the effects to be made on groups of forty animals, is lost Nevertheless the information obtained in both ways can be pooled with great advantage Of the four factors only ascorbic acid has an effect that approaches significance, it has decreased sensitivity twofold Cortisone alone has not altered the sensitivity, and we must attribute the significant change produced by cortisone, found in the full factorial analysis, to the fact that the synergism of cortisone with the other factors outweighs the absence of any effect of cortisone alone This is clear from the figure Moreover, the effect of combining cortisone with cabbage and the effect of combining cortisone with ascorbic acid both approach significance, and this is true, to a lesser extent, of similar combinations with ACTH No effect is produced by a combination of cortisone and ACTH in the absence of both cabbage and ascorbic acid Cabbage, given with ascorbic acid, both prevents the action of ascorbic acid and actually diminishes its effect—i e, increases sensitivity—by an amount which is almost significant This explains the significant interaction of cabbage and are ready to go home within about a fortnight from the operation.

Shortly after starting to employ this new procedure I found that the operation could be completed without haste in twenty to thirty minutes, involved a minimal blood loss, allowed of a complete "adenomectomy," and was generally followed by early ambulation with an easy and quick convalescence. The operation in fact gave such satisfaction that it soon became my routine method of prostatectomy, and now five years later continues to be so. I reserve perurethral resection for the fibrous glands, the sclerotic bladder necks, and the malignant obstructions. The suprapubic transvesical approach may be utilised when some additional bladder lesion, such as a new growth, a diverticulum, or a massive stone, is present, though my tendency now is to do a retropubic prostatectomy even when some concomitant bladder disorder necessitates a separate transvesical incision.

My first retropubic prostatectomy was done in December, 1945, and by November, 1950, I had personally performed the operation on 500 patients. During these five years my operations in hospital and private practice for the relief of prostatic obstruction numbered 704. The methods used were as follow:

Method	*No. of cases*
Retropubic prostatectomy	500
Suprapubic transvesical prostatectomy	64
Perurethral prostatic resection	123
Suprapubic cystostomy	17

ALTERNATIVE METHODS

The suprapubic transvesical prostatectomies listed include a series of 53 operations by the Wilson Hey (1945) technique, which in the earlier stages of this work I was simultaneously assessing. Since the retropubic operation became my method of choice, the suprapubic transvesical route has been used on 7 occasions only. The perurethral resections include 52 malignant cases where obstructive symptoms were unaffected or inadequately relieved by stilbœstrol. Suprapubic cystostomy as the sole procedure for relieving prostatic obstruction was used only when urinary retention supervened in patients with some other coexisting mortal disease or who had reached a stage of terminal senile physical or mental dissolution and were therefore unlikely to survive for long. The last 5 consecutive patients dealt with in this way were as follow: (*a*) aged 87, uræmic and diabetic, lived four weeks; (*b*) aged 82, physically active but senile, resumed normal micturition and dispensed with suprapubic tube, continues well after six months; (*c*) aged 82, gross hypertension, myocarditis and bronchitis, lived eight weeks; (*d*) aged 85, mental disorientation continues after ten months; and (*e*) aged 88, retention developed while under medical care for acute bronchitis and congestive heart-failure, lived 5 months.

SELECTION OF PATIENTS FOR RETROPUBIC PROSTATECTOMY

It will be apparent from the foregoing paragraphs that no patient seeking relief from a prostatic obstruction was denied operation by the retropubic method unless his prostate was diagnosed as of the fibrous or malignant variety and therefore best dealt with by perurethral resection or unless he was so enfeebled that his short expectation of life rendered anything beyond palliative relief futile. Advanced age, though naturally associated with an increased risk, was not deemed a contra-indication. Thus 80 (16%) of the 500 patients in this series were aged 75 or more: 29 were aged 75, 16 were aged 76, 11 were aged 77, 9 were aged 78, 5 were aged 79, and 10 were aged 80 or more.

If the prostatism is complicated by some other serious constitutional disease—e.g., a coronary lesion with severe myocardial changes—operation is not advised if the obstructive symptoms are not too severe and the patient can get along in reasonable comfort. If, on the other hand, a patient with a similar cardiovascular lesion has retention, or an obstruction which causes difficult micturition, retropubic prostatectomy is carried out. He is not condemned to a permanent cystostomy and the distressing conditions of living generally associated with that expedient. Everything possible is done to improve the cardiac weakness and vascular circulation. If weeks are needed for this purpose, or to permit adequate improvement of severe kidney damage resulting from long-standing back pressure or to correct a profound secondary anæmia, a cystostomy tube is inserted under local anæsthesia. Riches's (1943) method of suprapubic catheterisation is favoured for this preliminary procedure. If the optimum improvement is likely to be obtained within a week or two, the bladder is drained through an indwelling urethral catheter. This method of preparation is applicable to most cases. Two-stage retropubic operations have been carried out on only 16 of the series, and in 5 of them suprapubic tubes had been in place from four weeks to four years before the patients came under my care. In 2 other patients who were referred with suprapubic tubes it was found impossible to open up the retropubic space and the transvesical approach had to be used. The low insertion of the tubes and the considerable perivesical inflammation which had followed had obliterated the space from dense fibrosis.

MORTALITY

The over-all mortality for the 500 retropubic prostatectomies was 6%. The mortality in the 80 patients aged 75–87 was 8·7%, including 2 of the octogenarians. In the last 100 consecutive operations on patients aged less than 75 the mortality was 3%.

(1) A known sufferer from coronary sclerosis, aged 69, who had lost a leg in the first world war died on the tenth day from a sudden cardiac attack after helping to adjust his artificial limb.

(2) A diabetic, aged 68, who weighed 18 st., stood the operation well but on the third day developed an acute ileus with gastric dilatation to which he quickly succumbed.

(3) A man, aged 70, admitted with chronic retention and uræmia showed considerable improvement after suprapubic catheter drainage, but relapsed into uræmia after a second-stage operation and died on the third day.

POSTOPERATIVE COMPLICATIONS

The average patient running a smooth postoperative course has an aperient administered on the second evening, is allowed up to the commode the following morning, and has the catheter removed later that day. From then on he is encouraged to be up and about for a longer period each day until he is ready to go home. In my last 50 consecutive hospital cases, excepting one who remained in hospital for more than three months until he died of ventricular heart failure, and another who, because of a complicating mucous colitis, did not leave until the forty-seventh day, the average postoperative day of dismissal was the sixteenth.

An uncomplicated and speedy recovery is aided if during the first twelve hours after operation judicious supportive treatment is given. The transfusion of a pint of blood, begun during the operation and slowly completed on the patient's return to bed, is a great help to the aged prostatic, even when the blood-loss at operation has not exceeded a few ounces. During the immediate postoperative period the drainage from the urethral catheter must be carefully supervised and any blockage from clots prevented by squirting an ounce or two of sterile water through the catheter; suction by syringe is used to evacuate clots if necessary. A copious fluid intake is maintained and ensured, if required, by intravenous infusions. Urinary antiseptics, usually a sulphonamide with penicillin or streptomycin, are routine. In spite of these measures complications may arise.

pigs in each treatment group we might have demonstrated significant differences of tuberculin reactivity between groups that we have considered as similar, but such differences would probably be small and would not affect the general conclusions we have drawn from the gross mean differences observed between batches of five animals

As regards the nature of the hypothetical cabbage factor, the inhibition of ascorbic acid desensitisation by administered glutathione does not necessarily imply that the cabbage factor is an SH compound But it at least supplies a model for the action of the factor If ascorbic acid is protected from irreversible oxidation in the animal by tissue glutathione, as suggested by the in vitro studies of Borsook et al (1937), the maintenance of sensitivity at the high level by a cabbage diet and the change from low to high by injected glutathione, may both be due to interference with reactions involving the oxidation of ascorbic acid But whether the cabbage factor merely increases the concentration of glutathione like substances in the tissues or catalyses the reduction of ascorbic acid by such substances, in a manner analogous to the in vitro action of substances extracted from cauliflower by Hopkins and Morgan (1936), Crook and Hopkins (1938), and Crook (1941), cannot be determined until we know more of the quantitative aspect of the metabolism of ascorbic acid in relation to other tissue constituents of a particular piece of allergic tissue —e g, skin An interpretation of the tissue reactions in terms of in vitro biochemistry may then prove to be invalid

We have no evidence of how the cortisone cabbage factor antagonism is related to the ascorbic acid effect But, if the interaction of cabbage factor and ascorbic acid involves glutathione or is due to substances with some of the properties of glutathione, the reported diminution of the glutathione in human blood by administered ACTH (Conn 1950), or in rat blood by cortisone (Lazarow and Berman 1950), suggests that these hormones may act on metabolic systems in close relation with ascorbic acid In this connection it should be noted that the reducing capacity of the skin of our guineapigs, as judged by the intradermal injection of the oxidation reduction indicator dye 2 6 dichloro phenolindophenol (Rotter 1938), was greatly diminished for several hours after a single injection of ACTH or of cortisone

But the relation of all these phenomena is at present highly speculative

SUMMARY AND CONCLUSIONS

Using the response to intradermal tuberculin as a measure of allergic hypersensitivity in albino guineapigs infected with BCG, we find that

1 Guineapigs on a diet grossly but not completely deficient in ascorbic acid have a relatively high sensitivity This sensitivity is diminished by adding ascorbic acid to the diet, but not by providing ascorbic acid in raw cabbage

2 The factor in cabbage which leads to the inhibition of the desensitising action of ascorbic acid contained in the cabbage also inhibits the desensitising action of excess of ascorbic acid added to the diet

3 Single injections of cortisone or of ACTH diminish the sensitivity of guineapigs on a cabbage diet

4 Single injections of cortisone or of ACTH do not alter the sensitivity of guineapigs either on a basal diet deficient in ascorbic acid, or on this diet augmented by ascorbic acid.

5 The effect of a cabbage diet on ascorbic acid desensitisation is imitated by a single injection of glutathione

We conclude that there is in cabbage a factor which on ingestion leads to the inhibition of the desensitisation produced by the metabolism of ascorbic acid in the tissues of the allergic guineapig, and that the desensitising action of cortisone or of ACTH in cabbage fed animals is indirect, depending on the reversal of the cabbage effect by the hormones The cabbage factor may possibly be an SH compound

We are indebted to Dr Knud Tolderlund, of the State Serum Institute, Copenhagen, for the BCG, and to Dr F Bergel, of Roche Products Ltd, for the glutathione

RETROPUBIC PROSTATECTOMY

REVIEW OF 500 CASES

ARTHUR JACOBS

F R F P S

SURGEON IN CHARGE, UROLOGICAL DEPARTMENT, GLASGOW ROYAL INFIRMARY

FIVE years have passed since THE LANCET published Millin's (1945) first paper on his new method of prostatectomy by the retropubic extravesical approach The technique he advocated caused a considerable stir among urologists, who but some fifteen years earlier had begun to use the then comparatively new perurethral operations with increasing enthusiasm Millin, himself a former keen advocate and skilled exponent of perurethral prostatic resection, claimed that his operation represented a great advance not only over the loop and punch perurethral methods but also over the older suprapubic and perineal operations Because the prostate is essentially an extravesical structure, he was convinced that it should be extirpated by an extravesical approach. Although this can be done by perineal prostatectomy, he considered that method far from ideal, because of the possibility of sequelæ such as incontinence and urethrorectal or perineal fistulæ He therefore devised an alternative extravesical attack, the fundamental steps of which are as follow

The retropubic space behind the symphysis is exposed through a low abdominal incision, either transverse or vertical The prostate gland within its capsular coverings is defined below the bladder and cleared of overlying fat The capsule is then opened by a transverse incision 1 cm below the bladder neck The lower extremities of the lateral lobes are freed with scissors, and the separation is continued with the finger, working from below upwards until both lateral lobes and the middle lobe, when present, are delivered The complete adenomatous mass is then detached A wedge from the posterior lip of the vesical neck is now excised, this being an essential step in the operation to obviate subsequent contracture at the vesico urethral outlet The cavity is carefully inspected, spurting vessels are caught in forceps and coagulated with the diathermy, and any small residual adenomata or loose tags are removed with scissors so that a smooth surface remains A catheter is now passed along the urethra into the bladder, and the prostatic capsule is closed with a continuous catgut suture The wound is closed, a drain of corrugated rubber being delivered through a stab incision in the lower skin flap when a transverse incision has been used, and through the lower end of the wound when the incision has been a vertical one The drainage from the catheter must be carefully watched after operation to ensure that there is no blockage from clots The patient can generally get up on the second day, and void urine with ease when the catheter is removed on the third day Most patients

ERYTHEMA MULTIFORME EXUDATIVUM MAJOR (STEVENS-JOHNSON SYNDROME)

QUEEN ELIZABETH HOSPITAL BIRMINGHAM

Stevens and Johnson in 1922 described a "new eruptive fever" characterised by pleomorphous rash, ulceration of the mouth, purulent conjunctivitis, and severe constitutional symptoms.

As many workers have since pointed out, cases closely resembling those of Stevens and Johnson had been described long before. Most of them had been regarded as examples of "erythema multiforme exsudativum" (Hebra). In his original account in 1860 Hebra described erythema multiforme as a simple skin disease with no mucosal or systemic manifestations; in 1866 he referred to a case with pneumonia. At the turn of the 19th century several authors described erythema multiforme with buccal, conjunctival, penile, and vulvovaginal lesions, and urethral discharge (Quinquaud 1882, Kaposi 1893, Hanke 1901, Mracek 1902). Duhring (1896) reviewed 122 cases of erythema multiforme seen in Turkey; these were often accompanied by fever, a high proportion by mouth lesions, and a quarter by eye lesions; the disease was mostly mild. Other names under which cases indistinguishable from Stevens Johnson syndrome have been published are "ectodermosis erosiva pluri orificalis" (Rendu 1916) and "dermato stomatitis" (Baader 1925). More recently it has been shown that the skin need not necessarily be affected (Gilbert and Hing 1946), and that abacterial pneumonia may be a feature (Commission on Acute Respiratory Diseases 1946, Finland et al. 1948). Interest in the condition in this country has been aroused by Murray (1947) and Nellen (1947). Several writers have reviewed the literature. Some have tabulated a few features of published cases—e.g., Wentz and Seiple (1947), Soll (1947), and Fletcher and Harris (1945). Soll recorded the largest series of personal cases since Dühring, 20 being tabulated.

The present paper is an analysis of 77 previously reported cases and 4 of our own.

CASE RECORDS

Case 1.—A man, aged 22, was admitted under Dr E Bulmer on Feb. 28, 1949.

History.—On Feb. 17 he felt hot, as if he were going to have a cold, and next day he had a sore throat, headache, and cough. He was seen by his doctor on Feb. 21 and found to have pyrexia. On Feb. 23 his mouth looked red and inflamed, and he was given penicillin lozenges and sulphathiazole tablets. A patch of consolidation was detected clinically at the right lung base. By Feb. 27 he had ulceration of the lips, difficulty in breathing and swallowing, and a sore on his penis.

On admission his temperature was 100°F, and respirations 24 per minute. He looked ill and cyanosed. His conjunctivæ were injected. His lips were swollen and ulcerated, with black crusts on the lower lip (fig. 1). His tongue was swollen and red. The inside of his mouth showed extensive redness, ulceration, and bleeding, and a patchy formation of membrane. There was no membrane on the tonsils. The left tonsillar gland was enlarged. The percussion note was impaired at the right lung base, where the breathing was bronchial. The penis showed a meatitis, with a circular ulcer 1 cm. in diameter but no urethral discharge. The spleen was not palpable. There was no rash.

Investigations.—The Wassermann reaction of the serum was doubtfully positive. A white cell count showed 11,000 per c.mm., with polymorphs 83.7% (9207 per c.mm.) and eosinophils 1.7% (187 per c.mm.). There were a few pus cells in the urine. There was a cold agglutinin titre of 1 in 16, with a trace of 1 in 32. A swab from the mouth grew a mixed culture, with monilia predominating. Radiography of the chest showed consolidation of the right lower lobe.

Diagnosis and Treatment.—Stevens-Johnson syndrome was diagnosed, and no treatment was given other than boric lotion and 'Protargol' drops to the eyes.

Progress.—On March 3 a maculopapular rash developed on the chest, back, and extremities; it had gone by March 10. On March 3 also a blister developed on the left conjunctiva, near the inner canthus. This had ruptured on March 4 and was only just visible by March 16. The patient's temperature remitted to 102°F until March 1, and subsequently there were evening peaks to 100°F until March 5; thereafter it became normal. He was discharged symptom-free on March 16.

Case 2.—A boy, aged 18, was admitted under Prof. W Melville Arnott on Dec. 21, 1949, with rash and ulcerated mouth (figs. 2 and 3).

History.—He had a similar bout in 1943, with severely ulcerated mouth, swollen crusted lips, and ulcerated foreskin. He returned to school within 4–6 weeks. He also gave a history of angioneurotic œdema whenever he took aspirin, but he had not taken any before the present illness or before his attack in 1943.

On Dec. 8, 1949, he developed a cold and malaise and was given sulphapyridine 1 g. four-hourly from Dec. 15. His temperature ranged between 99° and 102°F, and on Dec. 17 he developed a swollen mouth, a rash, painful micturition, a urethral discharge, and an ulcer beneath the foreskin. The rash appeared first on the arms and spread to the legs, with sparse involvement of the trunk. The sulphonamide tablets were discontinued on Dec. 17 and intramuscular penicillin started.

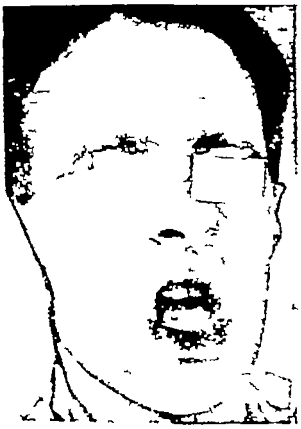

Fig. 1—Typical blood-encrusted lips (case 1 on thirteenth day of Stevens-Johnson syndrome)

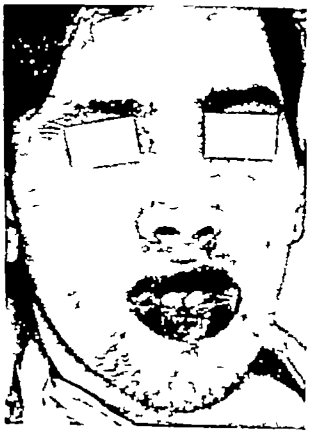

Fig. 2—Blood-encrusted lips of case 2 on fifteenth day of illness.

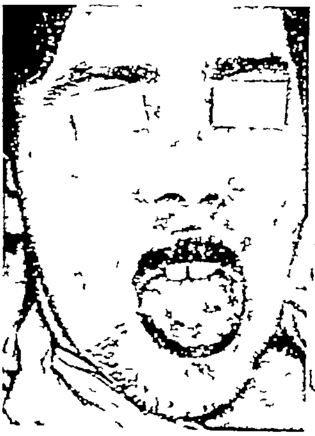

Fig. 3—Tongue of case 2 on fifteenth day of illness. Note thin saw-toothed edge and occasional bullæ.

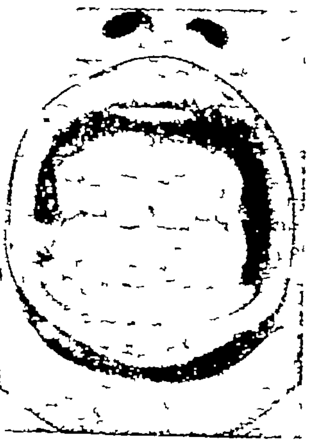

Fig. 4—Mouth of case 2 on twenty-eighth day of illness

Hæmorrhage, more severe than the frank hæmaturia normally expected during the first one or two days, may necessitate aspiration for clots On 2 occasions this reactionary bleeding was severe enough to necessitate a cystostomy In about 6–8% of cases a secondary hæmorrhage occurs, usually three or four days after removal of the catheter and severe enough to necessitate its reinsertion Usually all that is necessary is to aspirate clots through the catheter and leave it in place for one or two days, but sometimes the bleedings recur after clear urine has been voided In 1 such case only, after a third bleeding on the ninth day had followed two previous attacks, did I deem a cystostomy necessary The patient nevertheless went home eighteen days later with the suprapubic sinus completely closed

Leakage of urine through the wound is rare In the last 50 consecutive cases it has been a minor transient incident with 2 patients only Closure of the capsule with a continuous suture which takes an adequate bite of both flaps and secures the extreme ends of the opening is the surest way of avoiding it There have been 3 instances of prolonged leakage

In 1 it was a sequel to the cystostomy necessitated on 1 of the 2 patients who had had a severe reactionary hæmorrhage

In another it was a sequel to suprapubic drainage which was established at the time of operation because of profuse sanguinous oozing after the enucleation of a large septic prostate This patient had had a cystostomy with subsequent resection of the prostate eight years previously The suprapubic leakage in both instances persisted for three months until excision of the fistula and closure of the bladder proved completely successful

The third instance was in a man, aged 76, with overflow incontinence, gross urinary infection, alcoholic cirrhosis, and uræmia, the blood urea level being 125 mg per 100 ml Only slight improvement followed drainage with a suprapubic catheter Prostatectomy was performed in preference to leaving him with a permanent cystostomy The wound became infected and persistently leaked urine while he lingered in a suburæmic state He died sixty six days after operation

Osteitis pubis is a serious though fortunately rare complication It may follow any operation on the bladder or the prostate, cases having been reported after suprapubic cystostomy and perurethral resection On one occasion with me it was a sequel to a vesico urethral suspension for stress incontinence in a female There has been an incidence of 3 cases following the retropubic operations

One, early in the series, developed into an osteomyelitis This was a sequel to infection, probably due to trauma caused by the extraction of a large calculus through the bladder neck A sequestrum had subsequently to be removed

The other two examples were sequelæ to apparently normal postoperative courses In neither was the complication diagnosed until after the patients had returned home, when they experienced increasingly severe pain in the pelvic region, especially on attempting to stand Rest in bed for several months was required, and 1 patient took nearly a year before becoming entirely free from discomfort

In the last case in which I have seen osteitis pubis, the acute phase was apparently aborted by large doses of vitamin B combined with short-wave diathermy, as suggested by Lavalle and Hamm (1949) The patient, a woman, was up and about within four weeks of starting this treatment

Postoperative contracture of the bladder neck was a sequel in about 6% of cases before excision of a wedge from the posterior lip of the neck was recognised as a necessary step in the operation These contractures, when severe, were satisfactorily corrected by endoscopic resection, but the complication is now seldom encountered

LATE POSTOPERATIVE FOLLOW UP

The objective in any method of prostatectomy, apart from minimal mortality and morbidity, is a normally functioning bladder which permits the patient to retain urine for adequate periods and to empty the bladder with ease, a condition which should be permanent In the course of routine follow up dozens of patients have been tested for residual urine, and many of these have had cystoscopic or cysto urethroscopic examinations. Except for some previously mentioned instances in the earlier stages of this work, when a wedge was not excised from the posterior lip of the bladder neck, the excellence of the functional results, as judged by ease of micturition, a clear urine, complete control, absence of residual urine, and little nocturnal disturbance, has been striking To ascertain the long term results of the operation, a questionnaire was sent to 50 of 51 consecutive patients operated on from June to October, 1948, there having been 1 postoperative death in this group It was considered that an interval of not less than two years and three months after operation was adequate to permit the assumption that the functional status of the bladder then obtaining was likely to be permanent The patients within this group could be regarded as a fair average of the whole series, 22 of them being aged 70 or more 12 were aged 70–74, 8 were aged 75–79, 1 was aged 80, and 1 was aged 82 Malignant disease of the prostate had been proved in 5 cases An analysis of the information obtained from the replies to the questionnaire is as follows

Retropubic prostatectomies from June to October 1948, reviewed in January, 1951	50
Died since operation	10
From intercurrent disease, 7 2 aged 77 and 72 from cerebral arteriosclerosis, after 4 and 6 weeks 1 aged 62 from a general ‘break up’ after 7 months, 2 aged 62 and 78 from coronary thrombosis after 10 and 11 months, 1 aged 63 from malignant pancreas after 1 year 6 months and 1 aged 72, from pneumonia after 1 year 9 months	
From prostatic malignancy, 3 1 aged 69 at three months, 1 aged 82 at six months, and 1, aged 65 at 1 year 1 month.	
Untraced	1[*]
Available for report	39
Voiding urine with good force	*Yes* 35 *No* 4[†]
Complete control of bladder	*Yes*, 35, *No* 4[‡]
Nocturnal frequency *None* 11, *Once*, 19 *Twice*, 5, *Every 3 or 3 hours* 4	

---

[*] Left home town well a year after operation

[†] In 2 of the 4 without good force this is better than before operation, in 1 the same, and in 1 worse Two (1 better 1 same) had urethral strictures, sequelæ to former prostatic resections.

[‡] In 2 of the 4 without complete control there is merely dribbling at the end of micturition and in 1 there is precipitancy The 4th who is one of the 2 surviving malignant cases, has incontinence which developed eighteen months after operation

CONCLUSIONS

My purpose here has been to assess retropubic prostatectomy, and I have tried not to suppress any difficulties or complications encountered In dealing with large numbers of prostatic patients, and the constitutional ailments which so often accompany their advancing years, complete freedom from troubles cannot be expected, whatever procedure is used The prostatectomist must develop that method which he finds most suitable and successful, and I can say without hesitation that no method I formerly used has proved so consistently satisfactory I consider my experiences confirm the claims of Millin et al (1949) that this operation is associated with a relatively low mortality, is generally followed by an easy speedy convalescence and a minimum of morbidity, with an excellent functional result, and that of all the available techniques it “conforms most nearly to the modern surgical ideal”

Knowledge of the distribution of the molecular weights in a given polymer can most readily be obtained by its separation into fractions of different molecular weight, but in the case of P.V.P. no satisfactory method of fractionation has been found. Alternatively, a weight average molecular weight * (M_w) can be determined, and then the ratio of number to weight average molecular weights for any sample gives some indication of the distribution of molecular weights, since number average molecular weights are more sensitive to the low molecular weight molecules present, and the weight average is more sensitive to the high molecular weight molecules. At least approximately, the intrinsic viscosity * $[\eta]$ is proportional to the weight average molecular weight. Intrinsic viscosities and ratios $M_w/[\eta]$ are given in table I. There are variations in number average molecular weight and in molecular distribution between all samples examined. Sample 3 appears to be particularly abnormal and would not be passed for clinical use, but the variation between the other samples is probably the normal variation to be expected between different batches of P.V.P.

The osmotic pressure exerted by the P.V.P. component in aqueous or saline solutions depends on its concentration, its number average molecular weight, and, in more concentrated solution, on interactions between different polymer molecules, and not on the presence of any other components. The normal variations between batches of P.V.P. are such that the osmotic pressure of a 3.5% solution (as in plasmosan) is 0.033–0.040 atmospheres, comparable in range to the normal values for the colloidal osmotic pressure of blood.

P.V.P. is slightly surface active, a 0.025% solution in a neutral M/150 phosphate buffer lowering the surface tension by 5 dyne per cm. Experiments involving the injection of P.V.P. beneath films of albumin, globin, and fibrinogen at the air water interface indicate that any interaction between the protein and P.V.P. involves very weak forces of interaction.

TOXICITY

Immediate Toxicity

From the pharmacological point of view P.V.P., the important ingredient of plasmosan, is not toxic even when given in high dosage, the lethal dose for laboratory animals being 8 g. per kg. of body-weight, death being due to cardiovascular insufficiency attributable to hyperviscosity of the blood (Combined Intelligence Objectives Subcommittee 1945). Therapeutic doses are well tolerated.

In the original clinical experiments done in Germany with P.V.P. preparations pyrogenic reactions, albuminuria, and hæmaturia developed in some instances, but there is no evidence that any late harmful effects were seen. Follow up of the patients in this country, to whom plasmosan containing the new preparation of P.V.P. was given, some as long as three years ago, has revealed no late side effects from its use.

No ill effects follow the subcutaneous and intramuscular injections of 25% aqueous solutions of P.V.P., in which form it is extensively used in France as a retarding agent for penicillin, insulin, and certain hormones.

Remote Toxicity

The most likely late toxic effect of injecting foreign colloid substances into the circulation is the risk of deposition in fixed tissue cells of the body, although this is unlikely with the present preparation, which is so highly soluble and shows so little interaction with other materials. Rabbits of average body weight 2.5 kg. were bled 5 ml. per kg. of body weight and transfused with different quantities of plasmosan in deliberate overdosage, in amounts of 10–40 ml. of plasmosan per kg. of body-weight. The dose commonly used in man is about 8 ml. of plasmosan per kg. of body-weight. The rabbits were killed after 14 and 28 days. Apart from a small, probably agonal, hæmorrhage seen in one rabbit no macroscopic changes were visible post mortem. Dr. William Whitelaw, consultant pathologist, Birmingham, examined and reported on various sections from these animals. The lung, kidney, and liver of rabbits killed on the 28th day showed no change on any of the doses used. The livers showed no evidence that storage had taken place. In the kidneys from rabbits killed on the 14th day after a dose of 40 ml. per kg. of body-weight some swelling of the cells of the convoluted tubules was seen. These changes were not seen, however, in similar specimens taken at 28 days, suggesting that, if present earlier in these particular rabbits, they had later cleared. If these changes had had any relationship to the dosage of P.V.P. used they were transitory.

Four patients in our series, to whom 500–1500 ml. of plasmosan had been given, who later died from their injuries or disease, showed at necropsy no macroscopic or microscopic changes which could in any way be ascribed to plasmosan.

FATE IN THE BODY

When any foreign substance is introduced into the blood stream it is most desirable to know what becomes of it—whether it is excreted unchanged or undergoes modification in body fluids and tissues. This is particularly important when a considerable quantity of the substance is used, as with a plasma substitute. In metabolic studies of this kind it is most satisfactory if the fate of a given dose can be followed in the body by estimating blood levels at regular intervals and quantitative recovery of the original or breakdown products from body excretions. Investigations of the blood alone may not account for all the foreign substances in the body at any one time, because there may be selective distribution between the blood and the fixed tissue cells. So far it has not been possible in the case of P.V.P. to make quantitative studies to elucidate this point, but from many histological and biochemical studies it seems likely that the P.V.P. fraction of plasmosan in therapeutic doses does not become attached to fixed tissue cells but remains in the blood stream until it is finally excreted.

Until recently not more than 50% of a given dose of P.V.P. could be recovered quantitatively from the urine, by tests which have later been developed on the lines discussed below. The question arose whether the balance unaccounted for was retained in the body or excreted as an unidentified compound. It seemed unlikely, however, that significant quantities were retained in the body, because there was no clinical evidence of retention. An improvement in the technique of estimation shows that in ordinary circumstances 75% of the P.V.P. content of plasmosan may be recovered from the urine; a figure as high as 90% was obtained on a single occasion. With suitable adjustments this method can be used to determine blood levels.

Plasmosan exerts no ill effects on kidney function, and a typical fluid balance chart from a healthy person to whom 500 ml. of plasmosan was given is shown in fig. 1. Concurrent blood urea and urea clearance

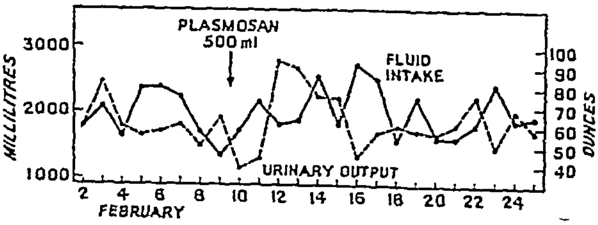

Fig. 1—Fluid-balance chart in relation to an infusion of plasmosan.

PLASMOSAN

RESEARCH LABORATORIES, MAY & BAKER LTD

FOR patients who have lost much blood, transfusion with appropriate amounts of whole blood is the treatment of choice The aim of the immediate treatment of shock is to restore the volume of circulating blood by improving the venous return, the cardiac output, and consequently the blood pressure Bayliss (1919) showed that the addition of 6% gum arabic to physiological saline solution could extend the period during which saline solutions restore the volume of circulating fluid by retarding the rate of excretion of fluids Unfortunately, inconsistencies in gums, and side effects due to long retention in the body, particularly in the liver, hindered general clinical use of this fluid

Various alternatives to gum have since been examined Infusion of natural plasma, or substitutes for it, does not of course restore the oxygen carrying power of the blood except in so far as all available erythrocytes are brought into use Attempts to improve the oxygen carrying power of artificially prepared solutions for infusion have been made by adding various hæmoglobin preparations to saline solutions, but these have proved unreliable and dangerous, principally because of renal complications due to free hæmoglobin in the blood stream (Holmes and Thrower 1924) But despite this lack of oxygen carrying power the prompt infusion of plasma and plasma substitutes can be life saving

Among several colloid substances suggested as agents to retard the excretion of saline solutions by the kidneys, polyvinylpyrrolidone (P V P) seemed promising (Hecht and Weese 1943) A saline solution incorporating a P V P compound was prepared and used in Germany with some success as a plasma substitute during the 1939–45 war, but side effects due to that particular preparation restricted its use elsewhere, particularly in countries where there were adequate supplies of natural blood products Improved methods of preparing P V P have permitted the development of a solution known as ‘Plasmosan,’ which is free from the objections to the German product and has proved safe and effective in clinical practice The composition of plasmosan is as follows

Polyvinylpyrrolidone	3 5 g	per 100 ml
Sodium (Na^+)	361 mg	,, ,,
Potassium (K^+)	22 ,,	,, ,,
Calcium (Ca^{++})	9 ,,	
Magnesium (Mg^{++})	0 06	
Chloride (Cl^-)	582 ,,	
Bicarbonate (HCO_3^-)	17	
Dissolved carbon dioxide (CO_2)	75	

The concentration of P V P is one which gives a colloidal osmotic pressure approximating to that of whole blood The total electrolytes make the solution isotonic The proportion of the various ions is similar to that in human plasma Early experience suggested that the solutions were more stable in the presence of a trace of free dissolved carbon dioxide The adjustment of any electrolyte imbalance is recognised as of increasing importance in transfusion practice Work is contemplated which may permit the development of a plasmosan capable of simple adjustment to the needs of particular cases on the lines suggested by Young (1951)

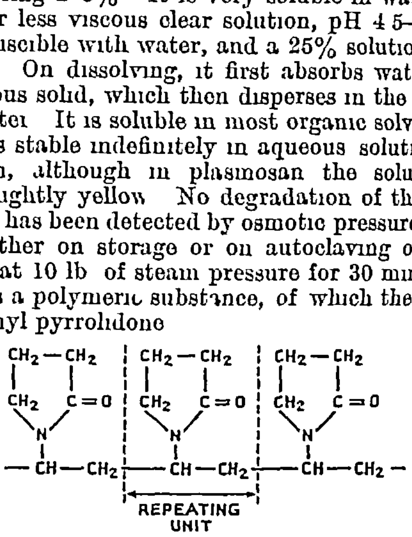
Before any plasma substitute can be considered suitable for clinical use, certain basic requirements must be satisfied It must have a high margin of safety Its viscosity, colloidal osmotic pressure, and tonicity must approximate to those of the recipient's blood. It should be retained in the body sufficiently long to be effective, and its fate should be known Blood grouping reactions should not be disturbed, or the erythrocyte sedimentation rate (E S R) unduly increased Kidney function must not be disturbed And no antigenic reaction must be excited

CHEMISTRY AND PHYSICAL CHARACTERISTICS

P V P , as used in plasmosan, is a white solid which is slightly hygroscopic, the normal water content of the powder being 2–3% It is very soluble in water, giving a more or less viscous clear solution, pH 4 5–7 0 It is readily miscible with water, and a 25% solution is easily obtained On dissolving, it first absorbs water to give a gelatinous solid, which then disperses in the remainder of the water It is soluble in most organic solvents

P V P is stable indefinitely in aqueous solution and in plasmosan, although in plasmosan the solution may become slightly yellow No degradation of the polymer molecules has been detected by osmotic pressure measurements, either on storage or on autoclaving of aqueous solutions at 10 lb of steam pressure for 30 minutes.

P V P is a polymeric substance, of which the repeating unit is vinyl pyrrolidone



POLYVINYLPYRROLIDONE

The possibility of small departures from this structure has still to be investigated From a consideration of its method of preparation, no sample of this polymer seems likely to contain molecules of a unique molecular weight (as found with the serum-proteins) but there will be molecules of a range of different molecular weights, as found with most synthetic polymers. The limits of the molecular weight range depend on the exact method of preparation of the polymer (see below) In aqueous solution the P V P molecule is believed to be more extended than the globular serum proteins Some evidence for this is obtained from the greater increase in specific viscosity and osmotic pressure with concentration in the case of aqueous solutions of P V.P than of serum albumin

TABLE I—AVERAGE MOLECULAR WEIGHTS AND INTRINSIC VISCOSITY OF P V P

Sample no	M_N	$[\eta]$	$\frac{M_N}{[\eta]}$
2	29 000	0 213	$1 4 \times 10^5$
3	140 000*	0 190	$7 4 \times 10^5$
4	49 000	0 196	$2 5 \times 10^5$
5	56 000	0 220	$2 5 \times 10^5$
6	56 000	0 196	$2 9 \times 10^5$

* Sample 3 is particularly abnormal and would not be passed for clinical use

Number average molecular weights * (M_N) have been calculated from osmotic pressure measurements on aqueous solutions, and typical values are given in table I

---

* Number average molecular weight (M_N) and weight average molecular weight (M_W) are defined by

$$M_N = \frac{\sum M \times N_M}{\sum N_M}$$

$$M_W = \frac{\sum M^2 \times N_M}{\sum M \times N_M}$$

where N_M molecules of actual molecular weight M are present in the sample
Intrinsic viscosity $[\eta]$ is defined by $[\eta] = \lim_{c \to 0} \eta_{sp}/c$

where η_{sp} is the specific viscosity of a solution of concentration c g per 100 ml solution.

A healthy man, aged 31, sustained three major open fractures in an accident and suffered severe shock Two hours after the accident, before an infusion of plasmosan 500 ml., the E S.R. was 3 mm. in 1 hour (Westergren) Three days later the E.S.R. was 30 mm. in 1 hour

Other patients have shown a similar rise in the E S.R. after plasmosan infusions

Since the introduction of many substances to whole blood induces hæmolysis, it was important to determine whether plasmosan had this effect In-vitro blood samples with and without the addition of solid P V.P were prepared After storage for four days spectrophotometry failed to distinguish between the concentration of free hæmoglobin in the plasmas from the two samples To observe whether any hæmolysis was caused in vivo, serum bilirubin estimations were made on patients to whom plasmosan had been given For example, in a man, aged 58, with hæmatemesis, the serum bilirubin level was 0 2 mg per 100 ml (4 units) before, and 0 2 mg per 100 ml. 48 hours after, an infusion of 500 ml. of plasmosan

In the composition of the saline solution in which P V.P is presented 0 05% $CaCl_2$ is present In the intact animal and in man the concentration of calcium salts in the circulation does not influence the risk of intravascular clotting Difficulties might, however, arise at the time of a change from plasmosan to citrated whole blood administered through the same giving set, owing to clots formed by the interaction of the Ca ion in plasmosan on citrated blood In practice we have encountered no difficulties from this theoretical possibility with blood to which 3% trisodium citrate and 15% glucose had been added Magendie et al. (1947), using 10% citrated blood in vitro, drew attention to the possibility of clotting, and recommended that the giving set should be washed through with normal saline solution before making the change

CLINICAL USE

Plasmosan has been given for various conditions in adults and infants for whom the use of fresh or reconstituted plasma would normally be indicated, and it seems to be interchangeable with plasma and to have no contra indications Arden et al. (1951) have used it in 37 cases The rate of administration should conform to that commonly used for plasma infusions, one or more bottles of 500 ml. being given as required. No side-effects from plasmosan infusions have been seen The largest amount given to any patient in our experience was 3500 ml. in a week. Because of its saline content excessive quantities of plasmosan may cause waterlogging, but before such a situation might develop alternative infusions would normally be considered In some instances no further infusions are necessary, but, if whole blood is needed, appropriate amounts can be given, when it becomes available, through the same apparatus

Since P V P does not occur in nature, previous contact is unlikely under ordinary conditions, and no antigenic reaction need be expected after a primary administration of plasmosan Though the possibility of sensitisation cannot be entirely ruled out, the chemical nature of P V.P makes such a reaction unlikely Attempts to sensitise guineapigs have failed

The results of some simple routine clinical pathological tests may be modified at times by the presence in body fluids of the large P V.P molecule, which has reducing properties In the blood this may be manifest in a measurable deviation from the true blood sugar level of the patient Again, reducing substances may be identified in the urine without sugar being actually present because of the properties of P V P A false positive test for albumin with the trichloracetic acid reagent or Esbach's quantitative method may be met Tests involving the use of cold nitric acid and heat tests are unaffected

Plasmosan keeps perfectly well and requires no special conditions for storage Thus it can always be at hand for the prompt treatment of any circulatory emergency in which transfusion is indicated and it may provide the sole treatment necessary

Our thanks are due to Mr W H George, Mr V S Hughes Davis and Mr E B Whittingham for collaborating, and to Dr Clara Cross for much help during this long investigation. We are indebted to Mr B Bell, Mr P O Kane, and Dr H G Kaul for some of the physicochemical measurements

WINDSOR GROUP OF HOSPITALS

AN efficient substitute for blood is needed because of the increasing number of transfusions given, the danger of plasma jaundice, and the threat of another war

Obviously blood is and must remain the most efficient fluid for combating shock. Plasma is second best and often very effective, but it occasionally causes toxic reactions or infective hepatitis Dextran seems to be as effective as plasma in the treatment of shock and is nontoxic, but it upsets blood grouping and is rather expensive and difficult to produce

MATERIAL

We have used 'Plasmosan' as a plasma substitute in 37 cases, either because of acute injury or during major operations

Accident or operation	No *of cases*
McKee or Smith Petersen pinning	9
Gastrectomy	6
Cup arthroplasty	5
Multiple fractures	4
Spinal fusion	2
Burns	2
Osteotomy of femur	1
Arthrodesis of hip	1
Partial colectomy	1
Amputation of leg below knee	1
Salpingo-oöphorectomy	1
Shortening of leg	1
Abortion	1
Laminectomy	1
Nephrectomy	1
Total	37

Most of the cases were major orthopædic cases which in our opinion would have required intravenous therapy either during or after the operation The average age was 54, the youngest patient was aged 7, and the oldest 84 Of the 37 patients 17 were male and 20 female

METHOD

Plasmosan was given at the start of each operation and was followed in many cases by blood The mixing of plasmosan with blood seems to be harmless Procaine 2 g in plasmosan 500 ml. was also used in several cases tests showed no alteration in renal efficiency due to the treatment.

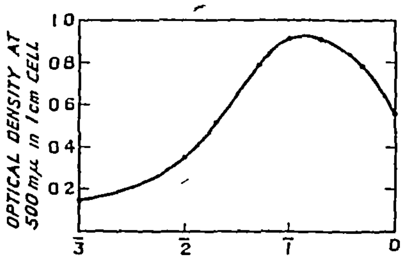

Fig 2—Variation of optical density at 500 mμ with concentration of P V P in solution.

METHODS OF ESTIMATION

Early reports on P V P indicated that it could be estimated colorimetrically after the addition of iodine. Methods have now been developed which allow of its estimation in urine and in serum.

The addition of an aqueous solution of iodine in potassium iodide turns an aqueous solution of P V P red brown owing to a broad absorption band at 500 mμ. The structure of the coloured compound has not been established, but it is believed to be due to the interaction of the I_3^- ion with the P V P molecule, since an alcoholic solution of iodide does not yield any coloured compound. The intensity of the colour depends on the concentration of iodine and potassium iodide in the reagent. The optimum concentrations are used in the methods outlined below. The colour intensity depends on the P V P concentrations, as in fig 2, hence, to get reliable results, it is necessary to ensure, by dilution, that the concentration of P V P in the solution tested is less than 0.1 g per 100 ml. The interference in the development of the colour by compounds in urine and serum can be eliminated by diluting the urine and by treating the serum with calcium chloride solution.

The influence of certain drugs on the estimation of P V P in plasma has been determined (table II). All the drugs were present in the plasma at a concentration of about 5 mg per 100 ml. Only ‘Flaxedil’ introduced a large error.

The colorimetric measurements were made at 500 mμ with a ‘Unicam’ SP 500 spectrophotometer and cells of optical length 1 cm. Any photo electric colorimeter with a filter with maximal transmission at about 500 mμ —e g, Ilford 603—can, however, be used with little loss of sensitivity.

In Urine (Concentration range 0.05–1.0 g per 100 ml)

(1) Dilute the urine 100 times with distilled water.

(2) To 5 ml of this solution add 1 ml of 0.006 *N* iodine in *N*/1 aqueous potassium iodide.

(3) The optical density of solution (2) is measured against water at 500 mμ.

(4) The concentration of P V P present in the original urine is found by using calibration curves determined experimentally with urine solutions of known concentrations of P V P.

In Plasma and Serum (Concentration range 0.02–0.8 g per 100 ml)

(1) 1 ml of plasma or serum and 10 ml of aqueous *N*/10 calcium chloride are gently boiled for $^1/_2$–1 minute. Loss of liquid is prevented by placing a funnel in the mouth of the boiling tube. The solution was filtered through a Whatman no 42 paper which has been proved not to adsorb P V P.

(2) 5 ml of the filtrate and 1 ml of 0.006 *N* iodine in *N*/1 aqueous potassium iodide are mixed, and the optical density against water is measured at 500 mμ.

(3) The concentration of P V P is found by using a calibration curve determined experimentally with plasma or serum solutions of known concentrations of P V P.

TABLE II—EFFECT OF DRUGS ON ESTIMATION OF P V P

Drug	Effect on P V P concentration estimated by iodine method
Morphine tartrate	No effect
Thiopentone	No effect
Atropine	No effect
Sodium penicillin	6% reduction
Procaine hydrochloride	4% reduction
Soluthiazole	3% reduction
Sulphamerazine	2% increase
Sulphadiazine	5% increase
Sulphathiazole	6% increase
Flaxedil	16% reduction

Fig 3, which is a composite curve, shows the excretion of P V P in the urine normally to be expected after the infusion of 500–1000 ml of plasmosan into patients with circulatory failure due to major surgical operations or to accidental trauma. The rate of excretion increases with the improvement of the circulation and greater urinary output. The plasma P V P level decreases steadily after the infusion, but its detailed correlation with the urinary excretion is difficult, since the plasma volume and its change on restoration of the circulatory volume are unknown. When plasmosan 500 ml. was injected, initial plasma P V P levels of about 0.35 g per 100 ml were obtained, which at the end of about 50 hours decreased to about 0.2 g per 100 ml. It has yet to be ascertained whether the high output of P V P during the first 48 hours is due to the excretion of P V P in the smaller range of molecular size, the larger molecular fraction coming later. The small fraction not accounted for in fig 3 may be explained partly by experimental errors and partly by delay in the excretion of large molecular particles. Possibly the large molecular particles may in the body be slowly degraded to smaller molecules, which are then excreted. Whether any P V P is lost in the fæces is unknown.

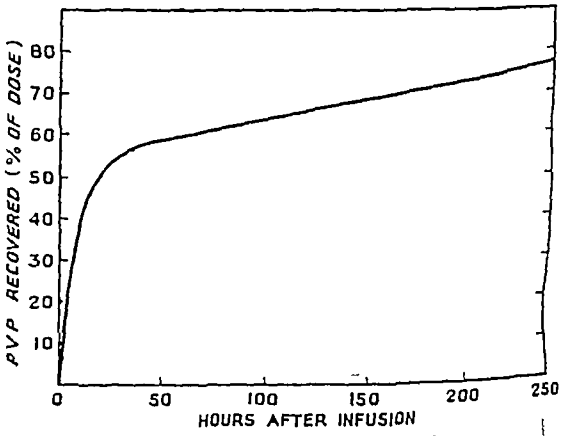

Fig 3—Recovery of P V P from urine.

EFFECTS OF PLASMOSAN ON WHOLE BLOOD

In vitro different quantities of plasmosan and whole or citrated blood mix readily, and the same applies under clinical conditions. With the plasma P V P levels likely to be met in practice (<0.5%) microscopy of erythrocytes reveals no significant changes. If excessive (10%) plasma P V P levels are used, the red cells become crenated. The clotting time and bleeding time of patients recently given infusions of plasmosan are unaffected, and blood grouping reactions are not disturbed. Erythrocytes do not absorb any measurable quantity of P V P at normal plasma P V P levels.

It has long been recognised that the addition to blood of colloid substances of high molecular weight raises the E S.R, and it was expected that the addition of plasmosan would do the same. In in vitro experiments the E S R increased with increasing concentrations of P V P. In clinical practice it is difficult to obtain accurate records, because often the patient's disease also raises the E S.R. The following case, however, illustrates what can happen.

TABLE II—RESULTS OF AGGLUTINATION TESTS

Strain of leptospira	Agglutination titres	
	On 7th day	On 11th day
L icterohæmorrhagiæ A	1 100	1 3000
L icterohæmorrhagiæ AB	1 100	1 3000
L canicola	1 30	1 3000
L grippotyphosa	0	0
L pomona	0	0
L ballum	0	1 300
L sejroe	0	0

Necropsy Findings—The body was well-developed, well-nourished, and icteric, with crural and preputial œdema There was a slight fibrinous pericarditis The pericardial and pleural surfaces showed petechial hæmorrhages The lungs were œdematous and, microscopically, contained small foci of bronchopneumonia The kidneys, which were equal in size, together weighed 420 g and showed a few cysts, the largest of which was 2 cm in diameter Both ureters were duplicated, and the renal pelves were slightly dilated On section of the kidneys there was eversion of the cut edges, and the yellowish cortices were friable Microscopy revealed a few scarred glomeruli Nearly all the glomeruli were normal, without fibrous thickening of Bowman's capsules The proximal convoluted tubules showed swelling of the epithelium, some mitoses, a few necrotic and calcified cells, and a narrow lumen. The distal tubules had a wide lumen often filled with granular brown casts. The epithelium was flattened, disintegrated, and often filled with brown granular pigment Throughout the interstitial tissues there were scattered collections of lymphocytes, plasma cells, clasmatocytes (macrophages), and a moderate number of polymorphs, especially in the cortico medullary area

The liver showed, histologically, dissociation of liver cells, but this phenomenon was entirely lacking in a formalin fixed specimen obtained by liver puncture immediately after death The cell dissociation therefore was a post-mortem artefact The liver cells were swollen and the nuclei unstable with many mitoses Some cells were necrotic The biliary capillaries were often filled with bile Disse's spaces were wide and œdematous Sections from the suprarenals, heart, pancreas, and testes showed small interstitial inflammatory foci similar to those in the kidneys Calf muscle showed microscopically necrosis, inflammation, and regeneration with giant muscle cells

Laboratory Investigations—Samples of blood serum for leptospiral examinations were obtained on the 7th and 11th days of illness The results of agglutination tests are given in table II

TABLE III—RESULTS OF CROSS ABSORPTION TEST

Titre against	Un absorbed	After absorption with		
		L ictero hæmorrhagiæ		*L canicola*
		A	AB	
L icterohæmorrhagiæ A	1 3000	0	1 30	0
L icterohæmorrhagiæ AB	1 3000	0	0	0
L canicola	1 3000	1 100	1 300	0

Since equally high titres were attained with both *L icterohæmorrhagiæ* and *L canicola* in the last sample of serum and no test was possible at a later date owing to the patient's death, a cross absorption test was done with the last serum sample, which clearly showed that the infecting organism must have been *L canicola* (see table III)

Examination of Dogs—The patient had owned three dogs which had not shown any symptom of illness before or during the patient's illness In two of these dogs leptospiræ were found in the urine on microscopy by dark ground illumination (table IV) and leptospiral agglutinins were detected in the serum Urine from dogs 2 and 3, which had leptospiræ in their urine, was inoculated into white mice and guineapigs All the mice remained negative, but from one of the guineapigs, inoculated with urine from dog 3, a strain of leptospira was isolated which agglutination tests proved to be *L canicola*

Examination of Patient's Wife—A search for agglutinins in the blood serum of the patient's wife also gave positive results

Strain	*Titre*
L icterohæmorrhagiæ A	1 300
L icterohæmorrhagiæ AB	1 100
L canicola	1 3000

Although a significant titre for *L canicola* was observed, the canicola infection of the patient's wife must have been very mild, since she did not remember feeling ill recently

DISCUSSION

Diagnosis—Leptospirosis was diagnosed when the results of the agglutination tests were known, but the species of leptospira responsible was not clear, because in the last sample of serum equally high titres for both icterohæmorrhagic and canicola strains were found It is in such cases that cross absorption tests may be very valuable and in the present case they proved what was supported by results of the examination of the patient's wife and dogs, that the leptospira responsible was *L canicola*

Necropsy revealed that the primary kidney disease which caused death was a lower nephron nephrosis The histological picture was exactly like that described in fatal cases of leptospirosis icterohæmorrhagica Jeghers et al (1935) and Ashe et al (1941) give the same description as Beitzke (1917) "There are swelling and more or less marked necrosis of the epithelium of the convoluted tubules and interstitial infiltrations of lymphocytes, and to a lesser degree polymorphonuclear leucocytes and eosinophils Granular and bile containing casts are common The glomeruli are unchanged in most cases The damage is thus predominantly in the tubules" There is some evidence from published accurate case records that in most instances the interstitial infiltration is conspicuous, especially in the cortico medullary area The cysts present in the kidney probably had nothing to do with the cause of death, contrary to what was thought at one time by one of us (J W W), whose opinion, mentioned by Weetch et al (1949), must therefore be withdrawn According to recent published reports lower nephron nephrosis seems to be nearly always the cause of the renal affection accompanying leptospiral infections

TABLE IV—RESULTS OF TESTS ON DOGS

—	Dog 1	Dog 2	Dog 3
Leptospira in urine	−	+	+
Agglutination titre with strain			
L icterohæmorrhagiæ A	0	1 1000	1 300
L icterohæmorrhagiæ AB	0	1 1000	1 300
L canicola	0	1 3000	1 3000

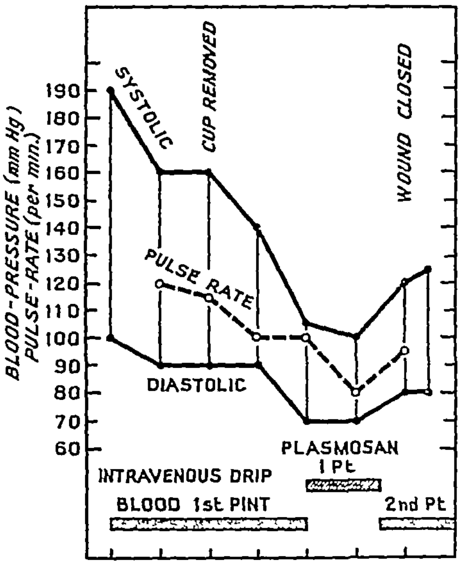
In the light of present experience, the treatment, though possibly preventing a further steep rise of the blood urea level after Nov 17 by restricting protein katabolism and increasing body fluids, must have been deleterious in many respects At that time (1946) there was some evidence, not confirmed since, that an increase of plasma sodium promoted the transfer of serum-potassium to the cells The normal figures of chloride and bicarbonate on Nov 19 do not mean that the sodium level (which was not determined) was normal too, it is even highly probable that it was far in excess, to judge from the œdema, meteorism, and frothy diarrhœa Part of the carbohydrate was given as lactose, since this was less disagreeable than cane sugar to the patient Probably the lactose had given rise to fermentation, and, since the patient was taking sodium carbonate, carbon dioxide was formed in the acid intestinal contents The same effect has since been seen in another patient taking large amounts of lactose and sodium carbonate

The average amount of plasmosan infused per patient was 600 ml , the smallest infusion being 500 ml , and the largest 2000 ml Plasmosan alone was given to 18 patients, and plasmosan and blood to 19 During the transfusions serial blood-pressure recordings were taken and charted with the pulse rate (see figure)

Plasmosan flows readily, and it has not been necessary to discard any, although some bottles have been stored for months

RESULTS

One patient died who had sustained burns There were no febrile reactions or urticaria which could be attributed to the plasmosan Any plasmosan that leaked into the subcutaneous tissues at the site of venepuncture seemed to cause no reaction In most cases plasmosan maintained the blood pressure satisfactorily, and in a few cases the blood pressure rose One pint was usually given in 45 minutes Increasing the rate helped to maintain the blood pressure if it was falling In operations which lasted more than 1¹/₂ hours, or when there was considerable blood loss, the use of blood became necessary to maintain the blood pressure and to replace the hæmoglobin After the infusion of plasmosan blood grouping was repeated in several cases and no difficulty was experienced Hæmodilution and anisocytosis were noted in a few cases from 2 to 4 days after the transfusion



Pulse and blood-pressure during revision cup arthroplasty under thiopentone (1 g), Flaxedil (80 mg) and cyclopropane and oxygen

There was no interference with wound healing, except for the presence of a hæmatoma in a few cases

The 4 patients with multiple injuries (2 bilateral compound fractures of tibia and fibula, 1 fracture of pelvis and wrist, and 1 fracture of humerus and femur) were treated with plasmosan alone None of these patients, however, were really shocked on admission, and the patients were operated on without a significant drop in the patient's blood pressure

In 2 major operations plasmosan alone was given, and, although the blood loss in each cases was significant, the blood pressure was well maintained during the operation

Case 1 —A girl aged 19, had a right subtrochanteric femoral shortening of 2 in performed, and the fragments fixed with a nail plate The operation lasted 2¹/₂ hours An infusion of plasmosan 1000 ml maintained a satisfactory blood pressure throughout The estimated blood loss was 1¹/₂ pints

Case 2 —A man, aged 58, with non union of a subtrochanteric osteotomy, had a bone graft and plate applied to the site of non union The operation lasted 1³/₄ hours An infusion of plasmosan 1000 ml kept the blood pressure satisfactory throughout The estimated blood loss was 1 pint

CONCLUSIONS

When a supply of whole blood is not to hand we advocate the immediate use of plasmosan as a sound and effective measure for maintaining the blood pressure

In most cases of shock plasmosan will restore blood pressure to normal for a time, and this has enabled us to economise in the use of blood

Plasmosan, in the quantities we used, seems to be an inert non-toxic fluid which will satisfactorily maintain the blood pressure during major operations with significant blood loss It keeps well, it is relatively cheap, and we are informed that it can be produced in unlimited quantities

We are grateful to our colleagues for information and data concerning their cases Messrs May & Baker Ltd supplied the plasmosan

THE FIRST KNOWN FATAL CASE OF CANICOLA FEVER

J W Wolff
M D Amsterdam
CHIEF OF BACTERIOLOGICAL DEPARTMENT, INSTITUTE FOR TROPICAL HYGIENE AND GEOGRAPHICAL PATHOLOGY

R van Dam
M D Amsterdam
PATHOLOGIST,
BINNENGASTHUIS

J E Minkenhof
HEAD OF DEPARTMENT OF INFECTIOUS DISEASES,
WILHELMINA HOSPITAL

AMSTERDAM

Reporting a fatal case of canicola fever in Sheffield in 1949, Weetch et al mentioned that up till then there had been only one death from this disease (Ruys 1947) Since no details of that case have been published, and death from canicola fever is still rare, we obtained the case record from Prof J G G Borst and present it here

CASE RECORD

A man, aged 55, was admitted on Nov 14, 1946, to the department of medicine of the University of Amsterdam, with five days' history of severe pain in the lumbar region and calves and a temperature of 104°F

On examination he was severely ill, with conjunctival injection, some small ecchymotic spots on the extremities, and a consolidation of the right lower lobe of the lungs No sputum was produced Pulse rate 110 per min, blood pressure 100/70 mm Hg Urine urobilin + + +, bilirubin negative, but after two days strongly positive, protein 0 1 part per thousand Blood urea 379 mg per 100 ml, chlorides 92 m eq , and bicarbonate 14 m.eq per litre Diagnosis bronchopneumonia and uræmia, probably due to Weil's disease

Treatment —Penicillin, 30,000 units eight times a day, protein free diet providing 2000–2800 calories daily, and containing 110 g of sodium bicarbonate, 52 g of sodium chloride, and 14 litres of water in five days

Course —The amounts of urine passed in the next four days were 485, 500, 380, and 360 ml Blood and plasma findings are set out in table I After death the bladder contained 715 ml of urine Severe œdema developed, and massive meteorism greatly hampered respiration and circulation and made peritoneal dialysis impossible There was also diarrhœa with frothy stools The blood pressure fell to 80/50, and the patient died on Nov 20 with symptoms of peripheral circulatory failure No signs of pulmonary œdema had been noted during life

TABLE I—BLOOD AND PLASMA FINDINGS

Date	Hæmatocrit (%)	Chlorides (m eq per litre)	Bicarbonate (m eq per litre)	Urea (mg per 100 ml)
Nov 16	35	92	14 5	379
Nov 17	36	82	16	476
Nov 18	34	79	18	486
Nov 19	32	81	13	535
Nov 20	34	94	27 2	530

TABLE III—COAGULATION TIMES (SEC.) OF IRRADIATED FIBRINOGEN

Time of irradiation of fibrinogen (min.)	Coagulation time of thrombin 0·2 ml. (6·5 units per ml.) + fibrinogen 1·0 ml.	Appearance of clot
0	13·8	Firm
1	14·0	Firm
2	14·8	Less firm
4	15·8	Thread like
8	23·0	Floccular

To provide further evidence on this point, a sample of purified fibrinogen prepared from citrated human plasma by ether precipitation (Kekwick et al. 1946) was subjected to ultraviolet irradiation in a quartz cell 4·8×4·8×1 cm., uniform irradiation being ensured by continuous stirring.

Irradiation at room-temperature of a 1% solution of fibrinogen in citrate saline solution for 1 hour led to the appearance of a floccular precipitate, the protein remaining in solution falling to 0·5%. The rise in temperature during the irradiation was less than 5°C.

A 0·2% solution was irradiated for various periods, and the coagulation time measured on the addition of thrombin. The results are summarised in table III. As the duration of exposure is increased, the coagulation-time becomes longer, and the clotting becomes more indefinite. This parallels the behaviour of plasma given increasing exposures in the irradiator.

SUMMARY

Though irradiation of plasma at 2537 Å increases the coagulation time and changes the clot, it does not increase the antithrombic activity.

The addition of purified fibrinogen to irradiated plasma brings back the coagulation time towards its original value, and the irradiation of pure fibrinogen prolongs the coagulation time as in plasma.

The principal effect of irradiation on the coagulability of plasma is due to modification of its fibrinogen.

Our thanks are due to Dr. R. A. Kekwick for valuable discussion and criticism.

DEFLATION OF DISTENDED BOWEL AT OPERATION

A. G. R. Lowdon
O.B.E., M.A., M.B. Edin., F.R.C.S.E.
ASSISTANT SURGEON, EDINBURGH ROYAL INFIRMARY;
LECTURER IN SURGERY, UNIVERSITY OF EDINBURGH

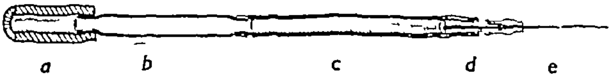
DISTENDED bowel is often an impediment to the surgeon at operation and a postoperative embarrassment, if not worse, to the patient. It has been taught that only exceptional circumstances will justify the surgeon in taking any measures during the operation to reduce this distension, and, because the content of the intestine is potentially infective, any measure which carries a risk of contaminating the field of operation from this source is inadmissible unless it is essential to the operation. On the other hand, most operations on the alimentary tract involve controlled exposure of mucosa at some stage, and with proper technique this can be made safe. The careful oblique insertion of a small needle into the lumen of the bowel and its equally careful withdrawal need be no more dangerous than the insertion of seromuscular sutures into distended colon (as in making the spur of a proximal colostomy for obstruction). If the needle is hollow and the bowel content passing through it can be removed completely from the operation field through a closed system, the procedure should not be a breach of aseptic technique. It should in this way be possible to remove the gaseous content of distended bowel without infecting the peritoneum.

A trial has been made of deflation of distended bowel with a hollow needle connected to the suction apparatus. In the last four years this technique has been used in more than 50 operations of various kinds; its benefits have often been obvious and gratifying, and there has been no reason to suppose that it was responsible for any undesirable complications. At first the measure was reserved for cases of severe distension where considerable benefit was to be expected from its relief, but more recently it has been used with advantage for less imperative indications.

Deflation of the bowel at operation may be practised more commonly than I am aware of, but I find that most surgeons in training, encountering it for the first time, regard it as heterodox and dangerous.

TECHNIQUE

The aspiration is done through a hollow needle with a diameter of 0·7–0·9 mm. The needle is connected to a metal fitting attached to a sterile suction tube. It is often advisable to aspirate at more than one point, and a fresh sterile needle is used for each puncture; it is then necessary to treat the fitting as septic and to hold a needle which is being removed from it or attached to it by grasping the hilt of the needle with a pair of forceps. After the final aspiration the suction tube is discarded.



Apparatus for deflation of distended bowel: *a*, suction tubing; *b*, glass connection; *c*, compressible tubing; *d*, metal fitting for needle; *e*, needle diam. 0·7–0·9 mm.

The needle is inserted through the bowel wall obliquely or, better still, so that its track passes for about 0·5 cm. through the muscular layers before penetrating the submucosa and mucosa. As the needle is withdrawn, the wall of the bowel is compressed on the shaft with a swab moistened in dilute 'Dettol' lotion. The swab and needle are then discarded. In the colon the puncture should be made through a taenial band. It has not been found necessary or considered desirable to close the puncture point with a suture.

Only gaseous contents can be profitably removed in this way. Even fluid in the small intestine blocks the needle so readily that no useful reduction of distension can be obtained by attempts to remove it. It is easy to tell by inspection and palpation of the distended loops if the distension is largely gaseous. In very distended small intestine fluid levels can be seen, and care must be taken to keep the point of the needle out of fluid.

When small intestine is being deflated, not more than three loops—about 60 cm. of gut—can be reduced by one puncture, and several punctures are often necessary to reduce widespread distension. In the colon the result is more dramatic, and experience has shown that almost complete deflation can be obtained by two punctures, one at the mid point of the transverse colon and one at the apex of the pelvic colon. To obtain the best results the suction must not be strong and the operator should be able to stop and start it at will. This can be achieved by having a short length of compressible tubing between the suction tubing and the metal fitting for the needle (see figure); the surgeon has merely to compress this tubing

SUMMARY

A fatal case of canicola fever is described

The cause of death was uræmia due to lower nephron nephrosis, with terminal bronchopneumonia

There is some evidence from published reports that the renal disease in leptospirosis is nearly always a lower nephron nephrosis

We wish to thank Professor Borst for his kind permission to publish the clinical data

COAGULABILITY OF IRRADIATED PLASMA

J W Lyttleton
M.Sc N Z , Ph D Lond
BEIT MEMORIAL RESEARCH FELLOW

L Vallet
B A Camb
OF M R C BLOOD PRODUCTS RESEARCH UNIT

LISTER INSTITUTE, CHELSEA

Cutler et al (1950) have shown that human plasma irradiated with ultraviolet light is less readily coagulable on the addition of thrombin They interpreted this fact as indicating an enhancement of the antithrombic activity of plasma

Experiments made by us on human plasma suggest that the main reason for the delay in coagulation after irradiation lies in a modification of the fibrinogen rather than an activation of the antithrombin

EXPERIMENTAL

In the apparatus used for irradiation (Habel and Sockrider 1946) plasma is allowed to form a thin film on the inside surface of a metal cylinder, 71 cm long and 5 1 cm in diameter, rotating at 1000 r p m at 8° to the horizontal The source of radiation, which is mounted axially within the cylinder, is a Hanovia 24 in low-pressure mercury vapour lamp from which more than 90% of the energy radiated is in the 2537 Å band The length of exposure is inversely related to the rate of flow of the plasma The average film thickness was calculated to be 0 11 mm and 0 085 mm at 3 1 and 1 7 litres per hr respectively

TABLE I—COAGULATION TIME (SEC) OF PLASMA ON ADDITION OF HUMAN THROMBIN

Treatment of plasma	Thrombin 0 2 ml (24 units per ml) added to plasma 1 0 ml	Thrombin 0 2 ml (12 units per ml) added to		
		Plasma 0 8 ml , citrate saline 0 2 ml	Plasma 0 8 ml cit saline 0 1 ml fibrinogen 1 % 0 1 ml	Plasma 0 8 ml fibrinogen 1 % 0 2 ml.
Agitation	7 6	15 0	15 0	17 0
Agitation and ozonisation	10 6	20 8	17 0	17 6
Agitation ozonisation and irradiation (flow 1 7 litres per hr)	21 4	44 0	21 2	21 0
Agitation ozonisation and irradiation (flow 3 1 litres per hr)	14 2	27 0	20 2	20 4
Untreated controls	8 0	16 2	16 0	17 6

During treatment the plasma is subjected to three influences the mechanical agitation and extreme extension of surface resulting from the rapid spinning , the presence of ozone produced in the tube by the ultra violet radiation acting on atmospheric oxygen , and the ultraviolet radiation itself

Samples of citrated human plasma (nine days old) were subjected to the following treatments

(1) Mechanical agitation of passing through the spinning tube

(2) Mechanical agitation and ozonisation with ozone passing from another source over the spinning plasma

(3) Mechanical agitation, ozonisation, and ultraviolet irradiation (as in normal irradiation treatment), rate of plasma flow 1 7 litres per hr

(4) As in (3) but rate of flow 3 1 lites per hr

(5) Left untreated, as controls

RESULTS

Table I gives the coagulation times of these samples on the introduction of thrombin, with and without the addition of fibrinogen The effect on coagulability of adding different quantities of thrombin to the samples is also shown

In table II the antithrombic activity of the samples is given This has been expressed in terms of the rate of inactivation of thrombin when incubated with samples of each treated plasma at 37°C During incubation, samples of the mixture were removed and used to coagulate a purified fibrinogen The coagulation times thus observed were converted to thrombin units by previous calibration, and the percentage of the thrombin inactivated in the first ten minutes' incubation was used to express the relative antithrombic activities of the plasma

TABLE II—ANTITHROMBIC ACTIVITY * OF TREATED PLASMA

Treatment of plasma	Thrombin inactivated by plasma (%)	
	Before defibrination	After defibrination with a trace of thrombin
Agitation	40	41
Agitation and ozonisation	36 5	33
Agitation ozonisation and irradiation (flow 1 7 litres per hr)	33	30 5
Agitation ozonisation and irradiation (flow 3 1 litres per hr)	33	30 6
Untreated controls	37 5	35

* Expressed as % thrombin inactivated in 10 min at 37°C when 4 75 ml of thrombin (12 units/ml) is incubated with 0 25 ml. of plasma

These results show that the antithrombic activity of plasma is not increased by irradiation , on the contrary it seems slightly reduced It is apparently increased by the mechanical treatment alone, but the increase is slight

The delay in coagulation of plasma by thrombin as a result of irradiation seems to be primarily due to an effect on the fibrinogen, and not to an increase in the normal antithrombic activity or to a heparin like substance causing thrombin inhibition This is suggested by two facts (1) the addition of fibrinogen to the system restores the coagulation time to a value near that of the control , and (2) the clot formed in irradiated plasma is abnormal Whereas in normal plasma the fibrin gel appears abruptly from a completely liquid condition, the treated plasma becomes progressively more and more viscous, with the result that the fibrin gel develops gradually

The fact that the coagulation times of treated plasmas are not restored completely to the value given by the controls is presumably due to the distribution of the added thrombin between the normal and modified fibrinogen molecules

The reduction in coagulability of plasma fibrinogen seems to be due both to the ozonisation and to the ultraviolet irradiation Mechanical treatment alone promotes coagulation to a slight extent abnormality—no free fluid was present, and only occasional explosions of bowel sounds in the right iliac fossa were heard on auscultation. The rectum was loaded with fæces which were removed with an enema without relief to the pain, and there was no local tenderness or abdominal tenderness on rectal examination. At this stage the blood pressure was 90/60 mm. Hg. The patient's condition did not improve, and he was diagnosed as having intestinal strangulation, but with no obvious explanation for the absence of bowel sounds. A plasma drip was started. The systolic blood pressure was 80 mm. Hg, but at times it was not recordable.

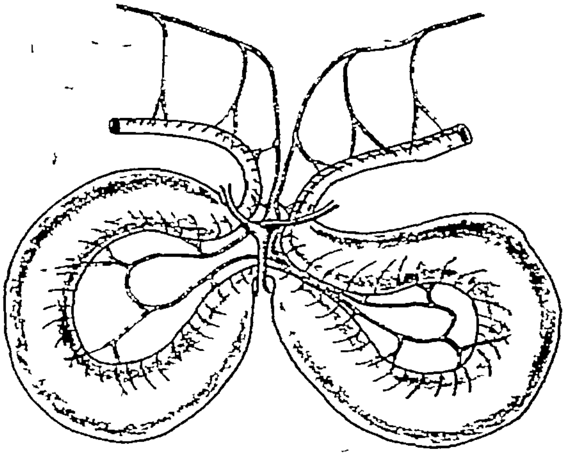
Operation at 2.15 P.M. under gas-oxygen and ether (Dr. N. G. Johnson) without any relaxant. When the abdomen was opened through a right paramedian incision, the first loop of gut to present was completely collapsed. This was followed proximally and, except for two stretches of about 5 in. which were about normally distended, it was completely collapsed up to the duodenojejunal flexure. Duodenum and stomach were normal, and there was no evidence of perforation or fluid. Traced downwards from the original presenting loop, the gut remained collapsed until about 2 ft. from the ileocæcal valve, where it was collected into a sort of rosette (see figure) by three short string-like adhesions. One of the adhesions completely, and the other two partially, occluded the gut. After the adhesions had been divided, the affected portion of gut was about 15 in. long. Where the occlusion was complete, the gut wall was congested and appeared slightly bruised; this section of gut was dilated to nearly twice the normal size. Distal to the adhesions the cæcum and the whole of the colon were completely collapsed. There were a few moderately enlarged mesenteric glands but nothing else abnormal. At the end of operation the systolic blood pressure had steadied to 80–90.

Postoperative Course.—Apart from the pint of plasma the patient was given no intravenous fluid. By next day he was much better, and he had no postoperative abdominal distension. His resting blood pressure was 112/70 mm. Hg. He was discharged from hospital on his tenth postoperative day with his wound healed and having been walking about the ward since his fourth postoperative day. Seen at the end of October he was fit and itching to return to playing rugby football. His bowels had moved daily without medicine since his discharge from hospital.

Follow up.—He was last seen on Aug. 3, 1950, when his weight was 7½ st., his appetite excellent, and his bowels opened daily without medicine.

DISCUSSION

Ogilvie (1948), Dunlop (1949), Handley (1949), and Macfarlane and Kay (1949) have reported cases of colonic obstruction for which no cause was found at operation, and this condition has been called Ogilvie's syndrome. There is, however, no fundamental clinical difference between such cases and those of spastic ileus reviewed by Aird (1949a).



One complete and two partial occlusions of gut caused by three short string-like adhesions six months after appendicectomy

In the present case there was complete occlusion of small intestine by an adhesion, and dilatation of gut proximal and distal to the site of complete obstruction. Two further adhesions, one proximal and one distal to the main adhesion, partially occluded bowel about 7 or 8 in. from the complete obstruction. The clinical picture was that of collapse, low blood pressure, scaphoid abdomen, few bowel sounds, and continuous retching, with little if any vomit. In view of these signs and symptoms, the findings at operation were surprising. Aird (1949b) has suggested that a widespread spastic ileus would be the most logical interpretation of the collapsed gut proximal to the adhesions.

SUMMARY

An unusual case of intestinal obstruction is presented in which there was complete mechanical occlusion of gut but in which the gut proximal to the obstruction was collapsed. The clinical picture was one of severe shock.

THE ANGINOSE TYPE OF GLANDULAR FEVER

REPORT OF A CASE REQUIRING TRACHEOTOMY

I. M. LIBRACH
M.B. Belf., D.P.H., D.C.H.
RESIDENT MEDICAL OFFICER, ILFORD ISOLATION HOSPITAL, ESSEX

GLANDULAR fever is now being diagnosed more often and is no longer regarded as rare. Its relatively protean manifestations have been described by Bernstein (1940), Smeall (1942), Halcrow et al. (1943), Contratto (1944), Tidy (1950b), and others.

The commonest manifestations, in my experience, are generalised splenic and lymph gland enlargement and the anginose form. Owing to the decreasing incidence of faucial diphtheria the anginose form of glandular fever has become more important in differential diagnosis, yet it is diagnosed with reluctance—possibly because it is natural to think of the more serious condition of diphtheria.

It is unwise, however, to consider that glandular fever is wholly benign. Deaths have been reported as due to neurological complications, hepatitis, ruptured spleen, and respiratory obstruction (Custer and Smith 1948, Ainley 1949, Lemierre et al. 1948). The reason why so few cases of respiratory obstruction have been published is probably that, in the absence of a Paul Bunnell test, most of them have been labelled as swab-negative diphtheria. None of the reviews cited above mentions this complication, nor does Joyce (1946) in a paper on the complications of glandular fever. Wintrobe (1946) even asserts that "in the anginose form laryngeal obstruction is unknown."

The earliest case and the youngest patient (aged 11 months) that I could find were reported by Chen and Teng (1941). Tracheotomy immediately relieved the symptoms.

Story and McCabe (1946) report a case in which emergency tracheotomy was successful in relieving complete respiratory obstruction in a man aged 20.

Lemierre et al. (1948) describe two further cases: a man aged 21 died from faucial obstruction in hospital, but in the second case a boy of 18 was probably saved by tracheotomy partially or completely as desired During the aspirations the assistant manipulates the bowel gently to bring the gas content of neighbouring loops up to the needle, in the colon this may be done by compression of the flanks

ILLUSTRATIVE CASES

Peritonitis and Ileus

A man, aged 64, was seen 24 hours after the onset of acute abdominal pain, he was very ill, with gross distension of the abdomen, loss of liver dullness, and signs of peritonitis Perforated peptic ulcer was diagnosed At laparotomy it was found that the loss of liver dullness was due not to pneumoperitoneum but to distended coils of small intestine between liver and diaphragm There was a perforation of an anterior duodenal ulcer, but it was found to have sealed spontaneously The perforation, reopened by the dissection, was sutured, and discharges were sucked out of the peritoneal cavity It was then appreciated that the bowel was so distended that closure of the abdominal wound would be difficult if not hazardous The distension was largely gaseous, and the bowel was deflated by aspiration so completely that the abdomen after closure was scaphoid In this case six punctures were made five in the small intestine, and one in the transverse colon In the postoperative period distension did not recur, intestinal sounds were heard twenty four hours after operation, the patient had a spontaneous bowel motion on the third day, and his recovery was uneventful

Subsequent experience has confirmed the impression that deflation is sometimes valuable in paralytic distension, but if it is to be as effective as in the case described above operation must be early In later cases the bowel content tends to be more fluid than gaseous I have considered, but have not yet attempted, the treatment of paralytic ileus by laparotomy for deflation with a needle and aspiration This measure would be justified only if percussion and X rays showed that the distension was largely gaseous

Intestinal Obstruction

The commonest indication for deflation of the gut by needle and suction is intestinal obstruction In obstruction of the distal colon distension is easily relieved by puncture and aspiration of the transverse colon It is often found that most of the cæcal gas can be removed by manipulating it gently to the needle I have not found it necessary to aspirate directly the cæcum or the ascending colon, puncture of the cæcum might involve additional risk because of the low vitality of the cæcal wall

If the obstruction is distal to the iliac colon, aspiration of the distended part of the pelvic colon is also desirable The colon should be aspirated at the highest point of a loop of transverse or pelvic colon which has been delivered from the wound, because the gases will then tend to rise to the needle

In colonic obstruction with gross distension it is advisable to make the first intra abdominal manœuvre a gentle exposure of distended transverse colon and insertion of a needle As deflation proceeds, further manual exploration becomes easier and safer I believe that this practice makes laparotomy and exploration practicable in some patients who might otherwise be better treated by blind cæcostomy

When the distended colon has been deflated, a proximal colostomy can be made at the site of election with much greater ease and safety Sutures to construct a colostomy spur are easily inserted, the deflated bowel is more mobile and more easily delivered, and the opening of the colostomy can be delayed without adding to the patient's discomfort

In cases of colonic obstruction it is seldom necessary to aspirate the small intestine, but in some late cases this has been done with added advantage

When the obstruction is due to volvulus of the sigmoid colon, deflation with a rectal tube passed by an assistant and manipulated by the surgeon is preferable if practicable However, if the twist is so tight that a rectal tube cannot be made to pass, initial aspiration of the distended loop with a needle makes its delivery and manipulation comparatively easy and safe

Two of the patients on whom I have deflated the colon by aspiration died of cardiovascular and respiratory complications within a week of operation Necropsy in both cases revealed no peritoneal infection due to the procedure

When the small intestine is obstructed, the distended coils are easily deflated if their content is gaseous, but in such cases the content is sometimes fluid and punctures should not be made unless it is obvious that the distension can be materially reduced A puncture in a loop of bowel which has to be left distended should be valvular and safe, but there may be some increased risk if an ineffective puncture has been made

Other Conditions

Gaseous distension of the colon may be encountered in any major abdominal operation When this is considerable it may interfere with closure of the abdominal wound and it usually leads to an uncomfortable immediate postoperative period for the patient On two occasions I have deflated the colon in the course of partial gastrectomy for peptic ulcer In each case the operations were facilitated and the patient had a smooth postoperative course

Deflation has also proved helpful in patients being treated for carcinoma of the pelvic colon by exteriorisation resection with clamps The reduction of distension of the proximal colon by removal of its gas permits the proximal clamp to be left on the bowel for three days or more Experience has shown that the gas does not reaccumulate rapidly and that postoperative discomfort is reduced

WARNING

Deflation of the bowel by aspiration should not be attempted without due indication With the muscular relaxation which modern anæsthesia can provide, its use simply to facilitate closure of the abdomen will rarely be justified When it is done in cases of paralysis or obstruction the minimal number of punctures should be made

SPASTIC ILEUS IN THE PRESENCE OF MECHANICAL OBSTRUCTION OF SMALL INTESTINE

J Grieve
B Sc, M B St And, F R C S E
LECTURER IN SURGERY IN THE UNIVERSITY OF ST ANDREWS

PROLONGED spasmodic contraction of gut has many causes (Aird 1949a), but it is seldom due to mechanical obstruction of the bowel, as in the case described here

CASE RECORD

A boy aged 14, had his appendix removed through a right gridiron incision in March, 1949 He was well thereafter until the early hours of Sept 23, 1949, when he woke between 4 and 5 A M with agonising central abdominal pain The pain was spasmodic but did not pass off completely at any time Between 6 and 7 A M he was seen by his doctor, who thought he might have a perforated ulcer *At that* time the boy's temperature was 97°F and his pulse rate 90

On admission to hospital about 10 A M his pulse was 108 and his temperature 96°F He was collapsed and greyish white He kept retching but brought up only a very small amount of watery material with little evidence of bile staining His tongue was clean and his abdomen concave There was no guarding or rigidity and apart from some tenderness just to the right of the umbilicus there was little

Hospital, Romford, for the pathological findings, and Dr G Laing Brown, medical superintendent, for permission to publish.

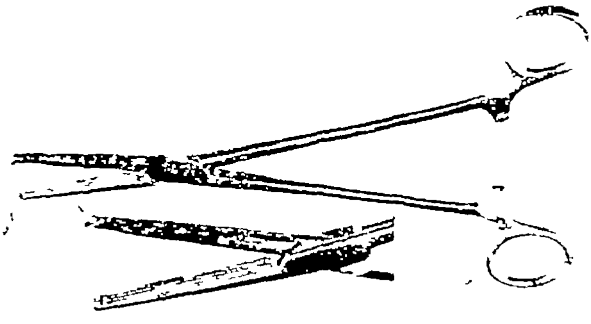
CLAMPS FOR HYSTERECTOMY

AFTER trying many patterns of hysterectomy clamp, I have evolved the following hybrid from what I consider to be the best features of several other clamps No originality is claimed, and graceful acknowledgment is made to Maingot, Mayo Ochsner, Kocher, and Sir Heneage Ogilvie

The clamp is rather heavily built but is light in the hand because of its good balance, it has a box joint and a rat toothed point The main feature is the longitudinal grooving of the jaw The clamp is $8^1/_2$ in. long, and the jaw is $2^1/_2$ in long



The virtue of this clamp is that, in grasping a thick vascular pedicle, such as the ovariopelvic or the uterine, no part of the pedicle can escape from the grip of the jaw With transversely grooved clamps this happens all too often. The loss of the uterine artery once or twice in those circumstances prompted the design of this clamp, which is made by Hawkins and has been tried and has found favour in the eyes of my colleagues It is equally suitable for abdominal and vaginal hysterectomy, and even general surgeons might perhaps find it of value on occasion.

I should like to acknowledge the kind coöperation of Miss Bartlett (theatre sister) Mr A. E Embray (curator of instruments), and Mr N K. Harrison (of the photographic department)—all of St Bartholomew's Hospital

it can be regarded as certain that the great bulk of the members of any modern community ought to be able over the whole of a full life span, to continue to contribute to the productive skills which are essential in such a community and to do so without undue fatigue or strain, but to their own happiness and satisfaction. —SIR FREDERIC BARTLETT F.R S in a foreword to *Skill and Age* by A T Welford and others (London, 1951)

Reviews of Books

Malignant Disease of the Female Genital Tract

STANLEY WAY, M.R.C O G, gynæcologist to the Newcastle Regional Cancer Organisation Royal Victoria Infirmary Newcastle London J & A Churchill 1951 Pp 279 *24s*

WRITTEN primarily for the practising gynæcologist, this is not only a textbook but also, in large part, a statement of the author's views and experience, supported by liberal use of case-histories The chapter on cancer of the cervix, for example, provides a fair summary of much that has been published in recent years together with much first-hand information

Mr Way's approach is based on his acceptance of the reliability of the biopsy cell count, associated with the names of Spear and Glucksmann to distinguish between radio resistant and radiosensitive tumours of the cervix He claims that by comparing a biopsy of cervix before irradiation with subsequent biopsies taken during irradiation, the response of the tumour to irradiation can often be foretold, and he believes that in the case which responds favourably to radium irradiation can do more and with a lower mortality than surgery In the case which responds unfavourably—the so called radioresistant case—the prognosis is bad but surgery holds out the best hope This view is contrary to that of Heyman, of Stockholm, who holds that in radioresistant cases surgery is dangerous and should be restricted to those in which at laparotomy, no extension of the growth beyond the uterus is found.

What Mr Way says on cancer of the ovary tends to confirm current ideas, the treatment of choice is surgery, in spite of an operative mortality-rate of 10–15%, and the value of postoperative X-radiation remains debatable Most will agree, too, that the treatment of cancer of the vulva is essentially surgical and that the results of radium and X rays have been very disappointing In the chapter on this condition, as indeed throughout the book, emphasis is laid on the importance of the lymphatic system in relation to the spread of malignant disease and its treatment For cancer of the vulva the author has adopted a method of extended radical operation, which he has completed in 75 cases with an operative mortality-rate of 14 6% Of the cases treated, 21 were operated on more than five years ago with an absolute survival-rate of 90% The most important steps in the operation are the widespread removal of vulva, and the resection of the lymphatic glands at least as far as Cloquet's gland The high survival-rate has been made possible by wide experience in the past ten years, by an agreement with his colleagues to submit to him all the cases they see, Mr Way has examined 127 patients with cancer of the vulva It is to be hoped that his plea for concentration of such cases in a few selected centres will succeed

Visual Anatomy

Head and Neck SYDNEY M FRIEDMAN M.D PH D professor of anatomy University of British Columbia Vancouver Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications 1950 *Pp 217 47s 6d*

LIKE so many of his colleagues, Professor Friedman has been depressed to find how little anatomy students remember a year or two after they have completed their dissection course He has therefore planned a series of books dealing with regional anatomy, designed as revision texts, both for undergraduates and postgraduates, and presenting only that material which is essential for the practice of medicine

The first volume of this series deals with the head and neck and consists of 93 illustrations each with a short facing descriptive text the aim being a visual rather than a textual presentation. These illustrations are distinctive line drawings by the author rather resembling woodcuts which omit details and concentrate on the main features they are sufficiently striking to compel close study The approach is synthetic the bones are gradually clothed with successive layers of muscle which in turn envelop vessels and nerves and are eventually covered by the enclosing deep fascia In each diagram the new facts are presented against the background of the preceding one and there is some deliberate repetition

Bower et al (1949) record a case in which tracheotomy was done and the patient, a boy aged 2, recovered

Jones and Jones (1949) report a case in a man of 22 in which tracheotomy became urgent and was done with relief of symptoms

Tidy (1950a) has known of tracheotomy being required in the severe anginose form, but he has had no personal cases

In the following case tracheotomy was successful

CASE RECORD

A schoolboy, aged 11, was admitted to hospital on April 15, 1950, as a suspected case of faucial diphtheria A throat swab taken at home had been negative for diphtheria, but had grown hæmolytic streptococci in profusion. The boy had been ill with sore throat since April 8, but he had recently developed difficulty in breathing He had been treated at home with penicillin and sulphamerazine His past history was uneventful He had not been immunised against diphtheria, but three years previously he had been found to be Schick negative

On admission he was acutely ill His temperature was 103 8°F, pulse rate 118, respirations 30 a minute His neck was much swollen, and his fauces were œdematous, as were his tonsils, which met in the midline and were covered with an extensive exudate Other systems were normal

Treatment and Progress —Faucial diphtheria was diagnosed, and the patient was given antiserum 200,000 units intramuscularly, penicillin 500,000 units six hourly, and oxygen by B L B mask Three hours after admission he was worse, his breathing being more difficult He was slightly cyanosed Five hours later he was very restless, and sedation with 'Sodium amytal' had little effect Ten hours later his restlessness had increased He was dyspnœic and cyanotic, and there was recession of the soft parts of the neck and chest The local throat condition, though difficult to see, was much as on admission In view of the respiratory distress Mr William Ibbotson did a high tracheotomy, which almost immediately relieved all distress The operation proved difficult because of bleeding and because of œdema of the muscles and fascial planes

Postoperative Course —Next morning (April 16, 1950) the patient was comfortable, and the faucial area was less œdematous, but the tonsils were covered with thick white membrane indistinguishable from that of diphtheria The blood pressure was 110/70 mm Hg A piece of membrane was removed from the inner tracheotomy tube, and forty eight hours later some more was coughed up through it On April 19, 1950, a maculopapular *rash appeared on the face, trunk and limbs, but the* local membrane was separating, and two days later the temperature settled and remained so until the patient s discharge On April 26, eleven days after the operation, the tracheotomy tube was removed On May 2, the throat was clean and all the swollen glands had subsided Tonsillectomy, done on May 22, proved difficult because of multiple capsular adhesions and excessive hæmorrhage from the left tonsil bed The patient was discharged free from all signs and symptoms on June 22

Bacteriology —Three examinations of throat and nose swabs (on admission, and two days and four days later) were all negative for diphtheria bacilli and hæmolytic streptococci (direct and culture) Throat membrane (coughed up) was also negative for diphtheria bacilli and hæmloytic streptococci (direct and culture) Post tonsillectomy throat and nose swabs were also negative for diphtheria and hæmolytic streptococci (direct and culture)

Serology —Wassermann and Kahn reactions were negative A Paul Bunnell test done on April 23 (eight days after admission) was positive to a titre of 1 in 512 after absorption with guineapig kidney Repeated on May 25, 1950 (forty days after admission) it was positive to 1 in 80, and after absorption with guineapig kidney 1 in 40

White-cell Counts —On April 23, 1950, there were 6200 white cells per c mm (polymorphs 44%, lymphocytes 51%, monocytes 4%, eosinophils 1%) On May 3, 1950, there were 7200 per c.mm (polymorphs 21%, lymphocytes 67%, monocytes 12%) The appearance of the mononuclear cells suggested glandular fever

Other Investigations —Radiography of the chest was normal on April 19, 1950 Electrocardiography was normal. The blood urea level on April 27, 1950, was 37 mg per 100 ml

DISCUSSION

Mitman (1950) regards glandular fever primarily as an infection of the hæmopoietic system As in other affections of this system there is a liability to faucial and gingival trouble, which is probably secondary Perhaps one could go further and call it an affection chiefly of the reticulo endothelial system—i e, infective reticulosis Tidy (1950b) says that all the blood forming tissues are affected, but the myeloid system less severely and for a shorter period than the other elements

Though glandular fever is primarily an affection of the first two decades of life, most of the published cases of respiratory obstruction have been in adolescents and young adults rather than in infants

In all the published cases the obstruction developed three to nine days after the onset of the illness The degree of obstruction has varied from complete obstruction requiring emergency tracheotomy to minor obstruction manifested by hoarseness and stridor In some cases there has been doubt whether to perform tracheotomy or not—e g, Johnson (1944) and Stroebel et al (1948)

The obstruction may be pharyngeal or laryngeal, or both, and it may be due to œdema or to membrane, or both. Ravenna and Snyder (1948) describe what they regard as the characteristic appearance of the œdema of the pharynx and larynx in this disease In more than half their cases the fauces were a brilliant red There was faucial œdema, the uvula at times resembling "a pear shaped bag filled with water" Usually no exudate was present The typical picture of follicular tonsillitis, Vincent's angina, and even diphtheria was also seen However, I cannot help feeling that there is no characteristic faucial picture in glandular fever, for, if we hold the ultimate site of the disease to be the hæmopoietic system, leukæmia and agranulocytosis as well as the common infections, are likely to produce similar appearances

Ravenna and Snyder describe a case of respiratory obstruction in a boy aged 3 years Laryngoscopy showed much œdema of the arytenoids, but the vocal cords were clear Next day whitish membrane covered the right arytenoid, and this condition continued for a week, after which the œdema spread to the epiglottis Extensive ulceration extended from the arytenoids into the glottis and down the trachea On the other hand, in the second case published by Lemierre et al (1948) laryngoscopy revealed neither œdema nor false membrane in the larynx, but there was enormous œdema of both tonsils and pharynx, which were covered with exudate Laryngoscopy was impracticable in the present case, but at tracheotomy gross œdema of the muscles and fascial planes was found, and pieces of membrane were extracted later through the tracheotomy tube This suggests that the larynx and the trachea were affected as well as the fauces

The obstruction seems to be due to inflammation The membrane represents devitalised and necrotic mucosa indistinguishable from that of diphtheria (Tidy 1950b, Smeall 1942) Œdema of the neck rivals that of diphtheria, but suppuration is very rare The faucial œdema causes anxiety, even obstruction, but despite this the patient does not look toxic

SUMMARY

A case of glandular fever in a schoolboy aged 11 years requiring tracheotomy is described The pathology of the condition is briefly discussed

I wish to thank Dr K M Hickey for his help in the treatment of this case Mr W Ibbotson for his surgical assistance Dr E Atkinson, of the department of pathology, Oldchurch

Hospital, Romford, for the pathological findings, and Dr G Laing Brown, medical superintendent, for permission to publish

Reviews of Books

Malignant Disease of the Female Genital Tract

STANLEY WAY, M.R.C O G, gynæcologist to the Newcastle Regional Cancer Organisation, Royal Victoria Infirmary, Newcastle London J & A. Churchill 1951 Pp 279 24*s*

WRITTEN primarily for the practising gynæcologist, this is not only a textbook but also, in large part, a statement of the author's views and experience, supported by liberal use of case-histories. The chapter on cancer of the cervix, for example, provides a fair summary of much that has been published in recent years together with much first-hand information

Mr Way's approach is based on his acceptance of the reliability of the biopsy cell count, associated with the names of Spear and Glucksmann to distinguish between radio resistant and radiosensitive tumours of the cervix He claims that by comparing a biopsy of cervix before irradiation with subsequent biopsies taken during irradiation, the response of the tumour to irradiation can often be foretold, and he believes that in the case which responds favourably to radium, irradiation can do more and with a lower mortality than surgery In the case which responds unfavourably—the so called radioresistant case—the prognosis is bad but surgery holds out the best hope This view is contrary to that of Heyman, of Stockholm who holds that in radioresistant cases surgery is dangerous and should be restricted to those in which, at laparotomy, no extension of the growth beyond the uterus is found

What Mr Way says on cancer of the ovary tends to confirm current ideas, the treatment of choice is surgery, in spite of an operative mortality-rate of 10–15%, and the value of postoperative X-radiation remains debatable Most will agree, too, that the treatment of cancer of the vulva is essentially surgical and that the results of radium and X rays have been very disappointing In the chapter on this condition, as indeed throughout the book, emphasis is laid on the importance of the lymphatic system in relation to the spread of malignant disease and its treatment For cancer of the vulva the author has adopted a method of extended radical operation, which he has completed in 75 cases with an operative mortality-rate of 14 6% Of the cases treated, 21 were operated on more than five years ago with an absolute survival-rate of 90% The most important steps in the operation are the widespread removal of vulva, and the resection of the lymphatic glands at least as far as Cloquet's gland The high survival-rate has been made possible by wide experience in the past ten years, by an agreement with his colleagues to submit to him all the cases they see, Mr Way has examined 127 patients with cancer of the vulva It is to be hoped that his plea for concentration of such cases in a few selected centres will succeed.

Visual Anatomy

Head and Neck SYDNEY M FRIEDMAN M D PH D professor of anatomy, University of British Columbia Vancouver Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications 1950 Pp 217 47*s* 6*d*

LIKE so many of his colleagues, Professor Friedman has been depressed to find how little anatomy students remember a year or two after they have completed their dissection course He has therefore planned a series of books dealing with regional anatomy, designed as revision texts, both for undergraduates and postgraduates, and presenting only that material which is essential for the practice of medicine

The first volume of this series deals with the head and neck and consists of 93 illustrations, each with a short facing descriptive text the aim being a visual rather than a textual presentation. These illustrations are distinctive line drawings by the author rather resembling woodcuts which omit details and concentrate on the main features they are sufficiently striking to compel close study The approach is synthetic the bones are gradually clothed with successive layers of muscle which in turn envelop vessels and nerves and are eventually covered by the enclosing deep fascia In each diagram the new facts are presented against the background of the preceding one and there is some deliberate repetition to drive home important points The figures are perhaps least happy when dealing with the interior of the skull, but elsewhere they are most clear and helpful

The accompanying text has the simplicity, force, and economy which we have learned to associate with Canadian anatomical texts There are one or two slips, such as the statement that stimulation of the cervical sympathetic causes flushing of the face, and no doubt, as the author anticipates, many will quarrel with the selection of material and the varying stress laid upon it It is clearly impossible to draw a hard and fast line between what is necessary for medical practice and what is not, but Professor Friedman has succeeded in producing a good and unusual book which will undoubtedly smooth the path of those revising the anatomy of the head and neck

Encyclopedia of the Eye

Diagnosis and Treatment Conrad Berens, M D , F A C S executive eye surgeon, New York Eye and Ear Infirmary professor of clinical ophthalmology, Post Graduate Medical School, New York University, Edward Siegel, M D , attending ophthalmologist, Champlain Valley Hospital, Plattsburg, New York Philadelphia and London J B Lippincott 1950 Pp 272 40*s*

The authors present this introduction to ophthalmology in the form of an encyclopædia, subject matter being arranged under the letters of the alphabet instead of following the usual anatomical system The text is sound accepted teaching, but it is difficult to see what precise advantage this form of presentation has over the more usual style In some cases the required information may be obtained a little more quickly, but there are also disadvantages, for adequate illustration is hardly possible, and indeed the colour reproductions are not up to standard and would have been better omitted

A Text Book of Venereal Diseases

R R Willcox, M D , consultant in venereal diseases, St Mary s Hospital, London London Heinemann Medical Books 1950 Pp 439 32*s* 6*d*

There is always a demand for a sound textbook on the diagnosis and treatment of venereal diseases, and particularly now, when so many new methods of treatment have been introduced within a few years This book is up to date, and covers the field reasonably well, some of the chapters, notably that dealing with congenital syphilis, are very good indeed But Dr Willcox's ideas about the pathology of the venereal diseases seem to be a little uncertain, and though his exposition is lucid, his style is careless and of a raciness perhaps out of place in this setting, Some obvious mistakes suggest undue haste in writing thus it would hardly be possible to reduce paraphimosis with the patient in the prone position The illustrations are a mixture of good and bad, and it is unfortunate from the point of view of students in this country that so many lesions are shown on coloured skins When photomicrographs are included the magnification is not given These small things cause unnecessary irritation, but fundamentally the book is sound

Animal Evolution

G S Carter, fellow of Corpus Christi College and lecturer in zoology in the University of Cambridge London Sidgwick & Jackson 1951 Pp 368 30*s*

A discussion of the theory of evolution of animals should be based, as the author says, on all the facts of animal biology But that is naturally impossible in a book of this size, so a selection of the more important facts is made before the theory is discussed Those facts are set out in five chapters palæontological data, genetics, the species in zoology, infraspecific categories, and competition, isolation, and natural selection The chapter on genetics, perhaps because it is a selection of facts that bear on evolution, is probably one of the best and most interesting of its kind By contrast the chapter on species is disappointing In the rest of the book too much space is given to discussing " pre adaptation " one can only adapt to a change, one cannot " preadapt " or " postadapt " The author tells us that " the object of the book is to discuss whether a theory can be put forward at the present time that will explain the means by which evolutionary change has been brought about " Evolution itself is taken for granted, but is rather artificially divided into micro-, macro-, and me evolution The argument of the book describes a circ the first part narrating the facts of evolution in ter of the theory, and the second part announcing t theory in terms of the facts Nevertheless it is full interesting information

Enterobacteriaceae

F Kauffmann, M D , chief, International Salmonel and Escherichia Centre, Copenhagen Copenhagen Munksgaard 1951 Pp 338 50*s*

The writer of this expensive monograph has a international reputation as an authority on its subject It is difficult to find any modern work on the bacteriolog of the enterobacteriaceæ to which he has not accorde critical appreciation, and to those who concern themselve with the identification and taxonomy of this group hi book will be indispensable It is full of useful and well designed tables, and, if the language seems stilted a times, the meaning is always clear Yet one must regre that so much earlier work is disregarded Some of it i certainly difficult to fit into our newer conceptions, bu it records the experience of serious scholars and we ca still learn from it The author's attitude is strictly tha of a laboratory worker, and he carries it to the point o omitting any note of the origin of the species of salmonella Those whose chief interests are in the pathology o epidemiology of this group of organisms will not fin his book very rewarding

Renal Function

Transactions of the First Conference, October 20–21, 1949 Editor Stanley E Bradley, Department of Medicine Columbia University, New York New York Josia Macy, Jr , Foundation 1950 Pp 172 $2 50

The Macy Foundation reports are difficult for the general reader, and even for the specialised research worker what is under discussion is not always exactly defined In this volume the section by Jean Oliver on histochemical studies of tubule function became finally bogged down by a semi-philosophical argument on the meaning of " secretion " But F Binkley discusses well the rôle of glutaminase, a kidney constituent which may act like an ion-exchange resin, R W Berliner deals with tubular secretion of potassium and acid, and L G Wesson with water absorption by the tubules The book gives much insight into American research and is valuable for the advanced investigator

---

An Eighteenth Century Lectureship in Chemistry (Glasgow Jackson Son & Co 1950 Pp 220 21*s*) —*This* well documented history, edited by Mr Andrew Kent, PH.D , tells of the life work of William Cullen, who did much to rescue chemistry from the toils of alchemy The extracts from some of Cullen s lectures make most attractive reading, and the account of Dr Joseph Black and his experimental work is equally good The foundation of the first lectureship finally established the status of chemistry as a special science, and a regius chair of chemistry at Glasgow resulted in 1818 For though the University of Edinburgh took an early practical share in the development of chemistry, Glasgow University has the honour of first encouraging the new science

N A P T Handbook of Tuberculosis Activities in Great Britain and the Commonwealth (13th ed London National Association for the Prevention of Tuberculosis. 1951 Pp 370 30*s*) —Dr Harley Williams, with the assistance of Mr H F Hughes and Miss Elizabeth Harrison, has brought up to date this complete and invaluable directory of hospitals, sanatoria, and clinics of regional hospital boards and hospital management committees, and of tuberculosis services in the British Commonwealth This new edition begins appropriately with an account of the old tuberculosis service in Great Britain and of the changes in its structure and in the legislation affecting it since July, 1948 The information relating to this country which follows is comprehensive, and set out clearly under the headings of the different regional boards The editor regrets that he has not, in this arrangement, been able to group local authority services together with those provided by the boards for, as he points out, one local authority may be in two, or even three, such regions More than a quarter of the book deals with tuberculosis services in other parts of the Commonwealth, Dr Williams has been disappointed only in his hope of including information about Pakistan

THE LANCET

LONDON SATURDAY, MAY 19, 1951

Acute Tubular Necrosis

A NEW and effective treatment often leads to striking advances in our knowledge of underlying pathology In 1949, BULL and his colleagues,[1] at the Hammersmith Hospital described a conservative method of treating anuria It will be recalled that, after the introduction of the artificial kidney by KOLFF, an instrument was set up at Hammersmith. This was used for many cases of anuria, and study of these cases led to the introduction of the new method, which was based on three simple principles (1) to avoid overburdening the body with fluid, (2) to reduce protein katabolism (and urea formation) to a minimum by means of a high-calorie, protein free diet, and (3) to maintain a rough electrolyte balance by giving no added electrolytes and returning any lost by vomiting With these principles in mind the Hammersmith group devised a mixture of peanut oil, glucose, and water (now often termed the Hammersmith Cocktail) which, when given by intragastric drip, has proved both simple and effective, and in uncomplicated anuric uræmia it has replaced both the artificial kidney and peritoneal dialysis The prognosis in cases of anuria due to tubular damage, such as may follow a mismatched transfusion, shock, abortion, concealed accidental hæmorrhage, surgical operation, or poisoning, has thus been remarkably improved, for the patient is kept maintained in good condition until the kidneys recover spontaneously

BULL and his associates have now reported investigations on renal function in cases of anuria treated by this new method[2] They point out that anatomically in such cases there is necrosis followed by regeneration of the renal tubular epithelium, and they suggest that the term " acute tubular necrosis " should replace the unsatisfactory title " lower nephron nephrosis " coined by LUCKE in 1946[3]—a suggestion which will certainly be applauded on this side of the Atlantic BULL and his colleagues recognise three functional phases in acute tubular necrosis (1) the phase of anuria or severe oliguria, (2) the early diuretic phase, when the daily urine volume first reaches a litre, and (3) the late diuretic phase, when tubular function is returning to normal. Little is known about renal function during anuria, it has been suggested that any glomerular filtrate that forms leaks back, through the necrotic tubular cells, into the venous plexuses, but this is speculation. BULL's observation that with anuria the total renal plasma flow is low and there is a considerable arteriovenous oxygen difference offers no support for the view that the disorder ensues from a " shunt " During the early diuretic phase tubular function is severely impaired, for the tubules cannot concentrate urea or creatinine, nor can they conserve electrolytes, so that sodium, potassium, and chloride are poured out in the urine, and the renal tubular extraction of *para*-aminohippurate is also reduced In this phase the maximal rate of tubular reabsorption of glucose was below normal in the two patients in whom it was measured, and the rarity of glycosuria in this condition and in the terminal stages of chronic renal failure requires further investigation. Study of the reabsorption of other " threshold substances," such as phosphate, calcium, and the amino-acids, during this period of tubular dysfunction may show that the loss of function is maximal in the distal tubule

The onset of diuresis after many days of anuria is a source of delight to the patient, the doctor, and the nursing staff, but BULL and his colleagues remark that, even when diuresis has set in, tubular dysfunction persists, and that the outpouring of electrolytes during this period may lead to serious symptoms and even death In the treatment of anuria, therefore, it is not sufficient to tide the patient over the anuric phase by means of the peanut-oil/glucose drip, maintaining equilibrium until the tubules regenerate in the early diuretic phase any dangerous loss of electrolytes must be made good. Why can the newly formed or regenerated tubular cell not concentrate the glomerular filtrate, and how does the kidney regain its remarkable power of maintaining electrolyte and water balance ? Study of the action of pituitary and suprarenal hormones during the early diuretic phase may throw some light on these problems

Two Ways of Grant-giving

" THIS demi-paradise," the dying John of Gaunt remarked with satisfaction, enumerating the advantages of living on a small island. It is possible nowadays to pick holes in his argument, but broadly speaking the blessings of our rough island life still make up for the drawbacks It is, for example, a blessing—or at all events a convenience—that the University Grants Committee (only some 18 persons strong) are able " to cultivate an intimate and in many respects informal relationship with those responsible for formulating and executing university policy "[1], " to survey the various fields of academic study with the objects both of securing that there are no unfilled gaps and also of avoiding unnecessary overlapping ", and to encourage the dual purpose of our universities, as centres of teaching and research, by means of block grants which the universities themselves apportion out among their undertakings The method is simple, friendly, and effective, but perhaps only suited to a country which is reasonably compact In the United States the Public Health Service has a similar duty of distributing grants from national funds—though to medical schools only, and almost entirely to subsidise research A committee appointed by the Surgeon General of the service, to study research and educational grants, fellowship programmes, and the costs of medical education, reports[2] that, to review applications and

[1] University Developments from 1935 to 1947 Report of the University Grants Committee London H.M. Stationery Office, 1948

[2] Medical School Grants and Finances Report by the Surgeon General's Committee on Medical School Grants and Finances In three parts Federal Security Agency Public Health Service Publication no 53 Washington United States Government Printing Office 1951

select the investigators and investigations to be supported, the service has set up 19 technical advisory groups (called "study sections"), each composed of about 10 members, most of whom are "affiliated with medical schools, hospitals or universities," and who serve for an average of five years The recommendations of the study sections are reviewed by one of five National Advisory Councils—the Health, Cancer, Heart, Mental Health, and Dental Research Councils—and the projects which the councils recommend are referred to the Surgeon General of the Public Health Service for final decision The amount of work entailed for the members of the study sections—who include "a large proportion of the Nation's most productive investigators"—"eats heavily into the time that they can spend on their own work" This has caused the committee serious concern, and they suggest that the time consumed in this way could be substantially reduced

At first glance it is not easy to see why the work of allocating grants should be so arduous American four year medical schools number only 72 (29 public, 43 private)—not much more than double our own 30 odd schools, though they are of course larger and more widely separated The chief difficulty seems to lie in the fact that applications for grants are made not by the medical schools and universities but by individual investigators or groups of investigators The study sections have therefore to keep a sound balance between the support of established investigators and the encouragement of promising newcomers—which, as the report says, calls for the most discriminating judgment It seems probable that a central body, receiving most of its evidence on paper, must sometimes get the answers wrong, but the committee are confident that this is rarely so they assure the medical schools that "with some rare exceptions that would occur no matter who picked the investigators to be supported, the grantees are selected objectively and a relatively incompetent man will seldom be supported while the application of a relatively competent investigator is turned down"

The sums to be distributed are very large, and have risen greatly in the last ten years In 1941, medical schools were spending $4 million a year on research, and Public Health Service grants were in the region of only $83,000, all of which was allocated to research on cancer During the war support for research in the medical schools came from the Office of Scientific Research and Development, and reached as much as $7 million in one year After the war grants from this source were replaced by other Federal funds, and the medical schools, of course, had other sources of research funds as well Thus by 1948 they were spending $17 million on research, half of which came from Federal sources, and half the Federal funds were distributed by the Public Health Service The committee are satisfied that such diversity of support assures "diversity of interest, philosophy, purpose and viewpoint," and effectively expands the range of intellectual inquiry

Funds for the maintenance of the schools themselves have not increased on anything like the same scale "basic operating costs," which in 1941 were $27 million, were $53 5 million by 1948—less than double, though in the same period research funds had increased more than fourfold This has led to some curious situations thus while research projects grow and flourish, and are allocated sums for new buildings, equipment, and staff, the teaching side of medicine is seriously hampered in its work, though students are increasing, 33 schools have recently had to curtail one or more aspects of teaching Moreover, buildings and equipment are in many cases inadequate for proper teaching The committee estimate that the schools need an additional $40 million a year immediately —$10 million for the public schools and $30 million for the private schools Where it is to come from they are not at all clear They do not believe that existing sources of funds will produce an additional $30 million a year for private schools in the foreseeable future, and think it unlikely (unless there is a sharp change in the outlook of State and city legislative bodies) that the $10 million needed by the public schools will be available either For us, who see teaching and research as the inseparable duties of a university or medical school, the obvious answer seems to be the conversion of research funds into block grants for both purposes But though the committee declare that "research and teaching in medical schools should not and cannot be considered apart from one another," and that research "cannot flourish where other functions of the school are starving," they are emphatically opposed to any sharing of research funds. The general financial problem, they say, would not be solved, and the one function of the schools now approaching a reasonable standard would be disrupted

They may well be right it is unlikely that sources of additional income for American medical schools have as yet been fully tapped But until adequate funds are found various people will experience some hardship Foremost perhaps must be put the students who are losing important opportunities 5 of the medical schools have curtailed or eliminated their courses in public health and preventive medicine, and 10 have retrenched on preclinical training The seasoned research-worker faces a much graver situation Grants are given to support the projects of individual investigators, or groups of allied projects constituting a programme Some large programmes have been supported for many years, but even so the support is for work described in advance by the investigators, and not for disposal at the discretion of the institution When the grant is made, the senior investigator is told, as a matter of courtesy, the number of years for which he will receive support, but there is no assurance of indefinitely continued support, nor do the committee favour any legislation to ensure it The schools, understandably, hesitate to establish too many senior faculty appointments with security of tenure, when these are supported by grants for research projects, for the grant may be withdrawn, and the schools are not in a position to accept financial responsibility for investigators thus left high and dry As a result there is a growing body of "extremely well-qualified investigators who live from hand to mouth without the security provided by firm attachment to a teaching institution" It might be thought that these are young men who are well justified in taking the risk for a few years in order to complete work in which they are keenly interested, but other passages in the report suggest that this is not so America cherishes the young, and the committee warn the study sections that "undue reliance upon past performance may lead to support of people who have passed the peak of scientific productivity and to inadequate support of those who are developing into leaders in their fields " They fear that too much stress is being laid on projects of long standing compared with new projects

The University Grants Committee strike a more tranquil note While they believe that, in this country, " the obligation of research stands in no present danger of being overlooked," they hint that " the notion of research, both for its own sake, and for the results that may follow from it, has acquired in some minds a disproportionate value " They confess that we have " no universities in which the provision of teaching blocks is not a necessity," and that both teaching and research are seriously hampered by lack of space, but where it is in their power to relieve these necessities they favour neither function, but impartially offer grants where they can do most good They admit that, since in research, they back institutions, not individuals, there is some tendency for the largest grants to go to the old established places with a long record of successful work, but lest this should lead to concentration of the best men in the universities which could pay the highest salaries, they have suggested a plan to reduce inequalities of salary, and in practice this has worked out well. The relationship of the State with the universities may fairly be described, they think, as a partnership, in which neither is out to get the better of the other While the U G C and the American Public Health Service evidently do not see eye to eye about policy, we feel that the grant-distributing methods of the British body may fairly be commended for study to the American one

Substitute for Nitrogen Mustards

THE "nitrogen mustard" group of β chloroethylamine compounds have proved a valuable addition to the means of treating chronic leukæmias, Hodgkin's disease, and some cases of mycosis fungoides But these compounds have disadvantages they must be given intravenously, and in a saline drip without which thrombosis of the vein is almost inevitable, they are powerful vesicants, and so must be handled with the utmost care, and they may cause a really unpleasant, if short-lived, attack of nausea and vomiting a few hours after administration These disadvantages have limited the use of nitrogen mustards to special centres, this is just as well because they are also powerful depressors of hæmopoiesis, and repeated blood counts are essential for safety Many attempts have been made to prepare a drug with similar action that could be given orally and would not cause so many unpleasant reactions So far the only compound of any value has been β naphthyl di 2-chloroethylamine, this was prepared by **HADDOW** and his co workers, whose code name for it is ' R48 ' R48 has been tested extensively in this country under the ægis of the Medical Research Council, and reports on its use have come from **MATTHEWS**[1] at Oxford and from **GARDIKAS** and **WILKINSON**[2] at Manchester Neither of these reports was enthusiastic R48 did produce a good therapeutic effect in some cases of chronic leukæmia—especially chronic myeloid leukæmia—and in Hodgkin's disease, but the general estimate was that the results were inferior to those from intravenous chloroethylamines

A new compound acting like the nitrogen mustards has now been introduced by **KARNOFSKY** and co-workers[3] in New York This substance is known as triethylene melamine (T E M), but it is not so different from the chloroethylamines as its name suggests The effect of the nitrogen mustards depends on a reversible chemical rearrangement that takes place when they are dissolved in water, and the important part of this change is the formation of very reactive cyclic ethyleniminonium compounds containing the group $-N\begin{matrix}CH_2\\|\\CH_2\end{matrix}$, triethylene melamine contains three of these groups attached to a triazine ring T E M was originally introduced in the textile industry for improving the finish of rayon fabrics, it is readily soluble in water, and solutions are prepared only in water or saline, since T E M reacts with many substances, it is relatively stable in alkaline mediums, but *reacts rapidly in acid solutions* T E M was first tested experimentally by **PHILIPS** and **THIERSCH**,[4] who found that it acted much like the nitrogen mustards but was notably less toxic On transplantable mouse leukæmia the effect of T E M was similar to that of the nitrogen mustards, and cells from treated animals could not be successfully transplanted in other susceptible animals Trials of similar compounds showed that at least two ethyleniminonium rings were necessary for activity

T E M has now been tested in man by **KARNOFSKY** and his colleagues, who gave the drug both intravenously and orally to patients with chronic leukæmias, Hodgkin's disease, lymphosarcoma, and neoplasms For intravenous use a 0 5% solution in isotonic saline is prepared, and this can be injected directly into a vein without a running drip, but, as with nitrogen mustards, great care must be taken to avoid any leak outside the vein, for otherwise a severe local reaction ensues The dose given in one injection was 2–3 mg, larger doses were liable to cause nausea and even vomiting As with nitrogen mustard, the effect of repeated doses is cumulative, and the maximum effect is reached one to three weeks after the last dose, T E M depresses the hæmopoietic marrow, but unless the dose is lethal recovery sets in within three weeks and regeneration is usually complete A safe total dose seems to be between 8 and 12 mg (0 12 to 0 20 mg per kg body-weight) in a single course Intravenous T E M treatment produced responses in a reasonable proportion of patients with chronic myeloid or lymphatic leukæmia or with Hodgkin's disease, and two out of seven patients with lymphosarcoma obtained some benefit, the response of five patients with reticulosarcoma was regarded as unsatisfactory Patients with any of these conditions whose lesions were refractory to irradiation or nitrogen mustard were also refractory to T E M The drug was tried on some patients with various tumours, but the results were negative On the whole, it was not thought that intravenous T E M had much advantage over nitrogen mustards Orally T E M tablets were given in doses of 2 5–10 mg daily The drug has to be taken on an empty stomach, because it reacts readily with many organic substances; so usually it was given one hour before breakfast. Since T E M is inactivated more rapidly in acid media, varying gastric acidity causes differences in the amounts needed by different patients to produce an effect; one way out of this difficulty would be to give it with sodium bicarbonate, but results with this technique are not yet known. There is no doubt that T E M by mouth depresses hæmopoietic tissue; in fact the depression may be more severe than that with intravenous administration, so dosage has to be controlled very carefully. Most patients tolerate 5 mg. a day, but those in poor health can often manage only 2·5 mg., while some of the more robust can take 10 mg.; unpleasant reactions usually take the form of nausea or vomiting. The initial dose is 2·5–5 mg. daily for two days only; at the end of a week the blood-count is checked, particularly the white-cell count, and if this is satisfactory a second course is given; further treatment is decided by the results of weekly checks. The maximum effect appears in two to three weeks, and then further treatment is decided by the patient's blood level, his general condition, and the effect on the lesion. KARNOFSKY and his co-workers state that if improvement has not occurred in 3–4 weeks, and moderate leucopenia and anæmia have been produced, further T E M treatment is unlikely to be of any benefit. Treatment with oral T E M is a highly individual affair, for each patient's dose must be adjusted according to his reactions; but the results in the chronic leukæmias and in Hodgkin's disease are quite as good as those with intravenous nitrogen mustard and much better than those with oral chloroethylamines such as R48. Two patients with mycosis fungoides were given oral T E M, and one responded. Results with a miscellaneous group of carcinomas have been very poor.

Triethylene melamine may thus enable us to treat the relatively slowly progressive cases of leukæmia and Hodgkin's disease by oral administration instead of by repeated intravenous infusions. This would be a welcome improvement; at the same time, however, T E M is a highly active and potentially dangerous substance that must be used only with all the precautions that apply to nitrogen mustards. Meanwhile it should certainly be given a wider trial; and the fact that a substance of this structure produces the same effects as the nitrogen mustards will suggest the synthesis of allied compounds, some of which may be safer to handle.

Annotations

A NEW SYNTHETIC STEROID

IN his centenary lecture to the Chemical Society in London on April 26, Prof. R. B. Woodward described the complete chemical synthesis of a new steroid compound by a method developed in his laboratory at Harvard. Steroids have, of course, been synthesised before—the hormones œstrone and equilenin by several different methods—but this is the first process which might be extended or adapted to produce 'Cortisone' or other corticoid compounds. The characteristic feature of the corticoids is their reactive functions in ring C of the steroid system (fig. 1), and it is the presence of reactive functions at positions 11 and 17 which make the new steroid potentially convertible into compounds of that type.

Professor Woodward's synthesis (fig. 2) starts from *o*-toluidine, an aromatic compound readily obtainable from coal-tar distillates and much more plentiful than deoxycholic acid, the present source of cortisone. The *o*-toluidine (I in fig. 2) becomes ring C of the structure; to this a four-carbon chain is attached to form a six-membered ring, and, when rings B and A have successively been added, this ring is opened and re-closed in the final stages to form the five-membered ring D. At each stage the chances of side-reactions or ring closures on wrong positions are reduced to a minimum by means of protecting groups; and by using reactions whose stereochemical effects are well established Professor Woodward and his colleagues ensure that the final product will have the configuration of the natural steroids, though it is not known to occur in nature. The compound is still racemic, but its resolution into optically active isomers is likely to be completed shortly. The structure of the new steroid has been confirmed by forming it, by a simple three-stage transformation, from natural 17-hydroxycorticosterone (Compound F; III in fig. 2) and showing that the resulting compound and the purely synthetic version are identical, with infra-red spectra that can be superimposed.

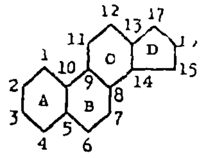

Fig. 1. Ring-system of steroid compounds.

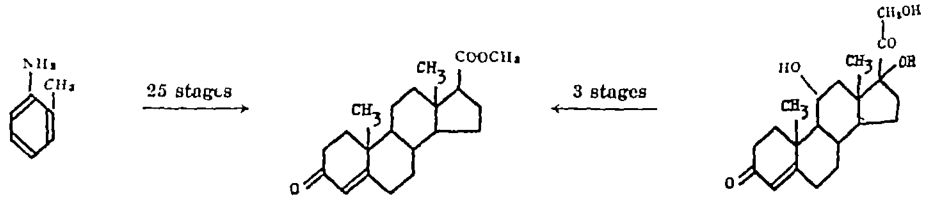

(I) *o*-Toluidine

(II) Woodward's Steroid

(III) Natural Compound F

Double bonds at 9–11 and 16–17 are not shown.

Fig. 2. I–II: 25-stage synthesis of Professor Woodward's new compound. III–II: 3-stage production of identical compound from natural 17-hydroxy-corticosterone.

It would be premature to hail this technique as a source of cheap synthetic cortisone in the near future. Even if extending the 25-stage synthesis to produce cortisone turns out to be unexpectedly simple, it is by no means certain that the product will be cheaper than the cortisone derived from bile acids. Professor Woodward gave no indication of the steroid yield obtained, but it is probably very small. Time will show how far his work can be applied to the large-scale manufacture of steroid hormones and their analogues. Meanwhile, there can be no two opinions about its great scientific value.

PLASMA SUBSTITUTES

THE interest shown in plasma substitutes during the late war, particularly in countries which had no organised transfusion services, has been revived by the unsettled state of the world and by a fear that the violent weapons now being developed may cause so many casualties that ordinary treatment by blood transfusion will become impossible.

The many substances used as substitutes include gelatin, dextran, and polyvinylpyrrolidone (P V P)

Experience of gelatin is confined almost entirely to the United States apart from its relatively brief effect, and the need to convert it from a gel to a sol by warming before use, it seems satisfactory Dextran is used in many hospitals here and in Scandinavia and Holland it restores blood volume satisfactorily, and remains in the circulation long enough to sustain it until the amount of circulating plasma protein is again sufficient for this purpose The third substance mentioned, P V P is a newcomer to this country, though as 'Periston' it has been used in Germany during and since the war, and as Subtosan' it enjoys a vogue in France. Two reports on P V.P made here under a British proprietary name Plasmosan' appear in our present issue It seems to be easy and cheap to make, it is apparently non-antigenic and non toxic, and it does not need special conditions of storage Urinary excretion accounts for some 50–55% in twenty four hours, and the question arises whether a substance to be used for restoring blood-volume could not with advantage be retained longer in the blood stream —a result that might be attained by adjusting the relative proportions of the smaller and larger molecular fractions The fate of the P V P which does not appear in the urine is not known with certainty German reports state that none is excreted in the bile Examination of the tissues of animals given large doses of P V P has revealed no morphological changes, but it would be instructive to have reports on chemical analyses of tissues The performance of certain clinicopathological tests is said to be affected

The preliminary report of the clinical results suggests that P V P can be used with advantage, particularly during surgical operations in which 'shock" occurs, but its blood volume restoring properties—in other words, its value as a plasma substitute—cannot properly be assessed until its effects on the circulation are known in more detail Observations in burns patients and those who have suffered blood loss or trauma will be needed to permit a full evaluation in particular we shall want serial records of blood pressure and pulse rate, of plasma protein, hæmoglobin, and hæmatocrit levels, and if possible of cardiac output and right auricle pressure The main function of any plasma substitute is to restore and maintain the circulating blood volume until the patient's own plasma protein returns to the circulation, and success in doing this is the main criterion by which such substances must ultimately be judged

ILLEGITIMATE CHILDREN

THOSE who undertake to help unmarried mothers need to know a great deal about the law, especially the statutes relating to custody and maintenance of illegitimate children, legitimation, adoption, paternity and blood tests, affiliation, inheritance, and nationality—as well as the benefits to which the mothers are entitled, and the arrangements for fostering and boarding out the children In a new booklet,[1] decoratively bound and nicely printed, Miss Lena M Jeger on behalf of the National Council for the Unmarried Mother and her Child, sets out all this necessary information and more Her clear well written paragraphs are like an arc lamp in the dark thicket of legal terminology and a good contents page, well chosen headings, and an index help to make the way still plainer

As Prof Alan Moncrieff says in an introduction, illegitimate babies start their lives under grave disadvantages Since 1918 there have never been less than 40 illegitimate infants for every 1000 children born alive The peak was reached in 1945, but even in 1949 the rate was 50 7 per 1000 live births Miss Jeger reminds us in a foreword that in 1918 the death rate during the first year of life was 91 per 1000 liveborn legitimate children, and 185—more than double—per 1000 liveborn illegitimate children In 1949 the comparable figures were 32 and 45—the rates, in fact, are drawing nearer to each other, but even so are grossly different The neonatal death rates have always been closer in 1918 they were 34 5 per 1000 legitimate live births and 66 4 per 1000 illegitimate live births, in 1948 the comparable figures were 19 3 and 27 4 This bears out the common experience of social workers that it is not in the first month of life but later in the first year that the illegitimate infant is exposed to specially unfavourable influences His chief trouble, of course, is that his mother has to go out to work, and she may not earn enough to get him well looked after But it is not only on the physical side that he suffers, lacking his mother for a great part of the day, he may become backward in his emotional development, and moreover, as Miss Jeger points out, "he is going to miss a father in the same way that any child who loses his father early, through death or separation, misses him" The baby whom the young mother was courageously determined to keep may grow into "a difficult, naughty and exhausting child", and both he and his mother will then need help

The National Council, founded in 1918, has always worked for legislative reform to help the illegitimate child Much progress has been made, as this little book bears witness But, as Miss Jeger puts it, "no legislation can compel anybody to give the unmarried mother what she usually most needs—friendship, understanding, and companionship in what is almost inevitably a lonely and deeply traumatic experience" Armed with this guide to the statutory provisions, the social worker—or even the untrained well-wisher—should be able to deal fairly easily with the material problems and turn her attention to the more fundamental needs of the pair she is anxious to help

DETECTION OF SPINAL BLOCK

THE Queckenstedt test is well known for its value in demonstrating spinal block, but in some cases of partial block the findings are equivocal, and occasionally there may be a normal rise of cerebrospinal fluid pressure even though myelography or operation discloses compression of the spinal cord Kaplan and Foster Kennedy[1] have investigated the effect of different positions of the cervical spine on the response to bilateral jugular compression (usually the test is carried out with the cervical spine straight or very slightly flexed) Of 294 patients with various neurological disorders, 12 showed an abnormal response to jugular compression with the cervical spine in either full flexion or full extension while there was a normal rise of pressure with the neck in the neutral position In 8 of these 12 patients exploratory laminectomy was performed, none had a spinal neoplasm, but in 4 there was a 'compressing exostosis of the cervical spine,' due either to arthritis or to a calcified disc protrusion at C5–6 level, in 2 a disc protrusion at C5–6 or C6–7 level, and in 2 adhesive arachnoiditis around the mid or lower cervical cord The whole series included 31 cases in which cervical cord compression was diagnosed clinically, these comprised the 12 cases already referred to 3 in which there was a complete Queckenstedt block with the neck in any position, and 16 with normal responses to jugular compression even with full flexion or full extension of the neck Exploration was performed in 7 of this last group no demonstrable compressing lesion was found in 6, while in the 7th there was a slight filmy arachnoiditis

Kaplan and Foster Kennedy regard this modification of the Queckenstedt test as helpful in the diagnosis of spinal compression at C5–6 level, which is the pivotal point for movement of the cervical spine on an immobile thoracic spine In their cases no removable cause of spinal compression was demonstrated by the manœuvre, but it entails no especial inconvenience to the patient and would be worth carrying out in patients with cervical cord lesions before deciding about the need for myelography

OUR MENTAL HOSPITALS

As our population grows, so do the numbers of our mentally sick For years now our mental hospitals have been getting more and more crowded, and—as the Board of Control note in their latest report [1]—the overcrowding on Jan 1, 1950, amounted to 14%, as against 12 2% on Jan 1, 1949 The results, as they point out, are not to be measured only in terms of actual overcrowding (though that is bad enough) the pressure on beds also obliges the hospitals to limit the number of voluntary admissions This means that preventive work and early treatment are both gravely hindered, which can only bring a greater load on the hospitals in the future

Three factors, the board find, have contributed to this serious situation In 1949 some 3034 mental hospital beds were still being used for other purposes, and though by 1950 the number had fallen to 2753, even these could be spared very ill At the end of 1949 there were 146,228 people under mental hospital care—an increase of over 1500 on the preceding year The board comment that the return of borrowed beds is not proceeding as rapidly as necessary, moreover, of the beds so far returned, over 2600 are still awaiting reconditioning and re equipment In the course of the year 1949–50 only 87 of these returned beds had been refitted, and the number of new beds provided for mental patients by the regional hospital boards was only 92—a total increase of 179 beds in a service treating an additional 1500 people This can only mean the setting up of extra beds in wards already full The situation would be eased if all the beds now available could be fully staffed, but at the end of the year a further 2279 beds were out of commission merely because staff could not be found for them Staffing, however, had improved on the whole since the previous year there had been an addition of 303 full time and 618 part time women nurses, and of 517 full time male nurses, with a fall in the ratio of patients to nurses from 7 6 to 7 4 for women and 5 5 to 5 4 for men This ratio is much too high Loss of trained and experienced staff, moreover, has been progressive, and "continuance of the service even at its present level is only possible by the use of less trained persons and by the very substantial use of part time nurses" Part timers, indeed, have proved invaluable, but their number cannot be increased indefinitely, and their employment brings its own administrative problems

Short handed, cramped, and housed, in the main, in inconvenient buildings, the mental service is yet giving an unflagging long term demonstration of how to make the best of things The incidence and death rate from tuberculosis in mental hospital patients is being steadily if slowly reduced, the death rate from gastro intestinal infections has fallen to less than 1 per 1000 patients The death rate per cent of the average number of residents, though, in 1949, it was 1 17 above the rate of the previous year, is nevertheless below the mean percentage for the past ten years—which means that very good work has been done during a time when overcrowding has been steadily increasing

Social and cultural activities—as well no doubt as occupational therapy—are everywhere gaining ground In 1949 the Council for Music in Hospitals was giving concerts in 44 mental hospitals, while the Picture Library Scheme organised by the British Red Cross Society was already supported by 30 hospitals The report does not mention the progress made in establishing therapeutic social clubs or in the setting up of art classes, but many hospitals are now interesting themselves in these forms of therapy In 56 hospitals the Women's Voluntary Services continue to give help and are now undertaking follow up visits to patients—a piece of service which may do something to replace the community care formerly given throughout the country by the National Association for Mental Health

Methods of collecting statistics from mental hospitals have been revised, and an index card has been adopted for individual returns on patients admitted to mental hospitals in England and Wales The completed cards are sent to the General Register Office, and punched cards are prepared from them, from which statistics can be produced mechanically The system came into operation at the beginning of 1949, and is working smoothly, and at the same time regulations for the keeping of hospital registers were brought up to date A scheme is being prepared to deal with patients' earnings Sometimes convalescent or stable patients go out to work for local employers and earn several pounds a week The hospital is entitled to recover from them such part of the cost of their maintenance and incidental costs as seems reasonable Part of the remainder is to be kept by the patient as pocket money, and the rest will be banked on his behalf This means that on discharge he has a sum of ready money Moreover, since his capacity to earn is well established, his status usually rises with his relatives and friends

BREAST CANCER IN MOUSE AND MAN

THE discovery in mice of Bittner's milk factor, a virus like agent transmitting heritable mammary tumours to young sucklings, naturally led to attempts to identify a similar factor in human milk It may cause surprise that, though Bittner discovered the milk factor about 1936, only in the last couple of years have similar reports about human milk come to hand This is because in man identification of such a factor depends on a different method The mouse agent can be found by experimental transmission to other susceptible mice Even these experiments take nearly two years of the life of a mouse, and during this time the young test mouse is growing up, maturing, and herself becoming a cancer prone breeder Along those lines—and there is no other direct biological test, for a human agent would not be transferable to mice—it will take a very long time, the collaboration of several generations of observers, and much careful well planned work to obtain similar information in man about the relation between breast cancer in mothers, breast feeding, and breast cancer in daughters and grand daughters Nevertheless such records are being undertaken

Meanwhile some very small particles, varying in diameter from 200 to 1200 Ångstrom, have been seen with the electron microscope in preparations of mouse mammary tumours and mouse milk both at Leeds [1] and in the U S A The precise relation of these particles to Bittner's milk factor is not yet decided, but it is significant that when the factor is known to be absent the particles can be found only very rarely The Leeds workers have now reported some findings in human milk [2] These are tantalisingly equivocal, for although particles were found in 11 out of 11 breast tumours and in 4 out of 4 samples of milk from patients with breast cancer, they were also found in 11 out of 12 samples of normal milk, 1 of which contained a large number of particles It may be that some of the producers of these

11 positive samples will in the future develop breast cancer, but it is improbable that all will do so. These findings, which accord with others in the U.S.A.,[3] make it necessary to interpret the results with caution. In the realm of electron microscopy, which is now making such small particles visible, we are still in the stage of exploration.

This work, however tedious and apparently unrewarding, must be done, because the milk factor is one of the few clues we have to a continuing cause of cancer. One of the rewards of the work is, perhaps, to set others thinking and wondering about the chances that the somewhat peculiar multiple hereditary tumours of mice are, in their natural history and behaviour, really comparable with human breast tumours, which more often than not are single. The mouse also develops solitary mammary tumours; but these are found in oldish breeders of strains from which Bittner's milk factor is known to be absent; nor can the factor be recovered from these tumours. Are these not more comparable with the human disease than the multiple heritable tumours? Possibly both types occur in man as in the mouse. Descriptive pathology may have overlooked multiple origins or confused them with regional neoplasia; still, it is not very likely that the appearance of seeding, seen in mice, with a great many adenomas together with two or more frank tumours at separate sites, would have escaped attention. The seeding itself is a most odd feature, which suggests that packets of particles or milk factor have settled out of the blood-stream from time to time in some favourable nidus. We still do not know what conditions encourage this focal infection followed by cell proliferation, except that it requires a special susceptibility that is inherited as a mendelian dominant, and an adequate amount of ovarian hormone. The purely focal contribution is unknown.

PSYCHOSOMATIC MEDICINE AND PSYCHOTHERAPY

PSYCHOSOMATIC medicine commands widespread attention in contemporary medical thought—even in 1943 Dunbar[4] listed 2400 references—but it remains a term vaguely understood and loosely employed. It was therefore an important occasion when, on May 8, Prof. Ernst Kretschmer, of Tubingen, probably the greatest living pioneer in the study of inter-relations between constitutional types and their mental and physical disorders, addressed the psychiatric section of the Royal Society of Medicine.

Professor Kretschmer, whose paper was translated by Dr. E. B. Strauss (who is also the translator of his *Textbook of Medical Psychology*), declared that there was a need to define the concept of psychosomatic medicine. Physicians tended either to think of disease processes in terms of organic changes, or else to go to the opposite extreme and ascribe them all to psychogenic factors. Psychosomatic diseases should be regarded, not as discrete entities, but as cycles or sequences. Emotional causes produced autonomic and endocrine reactions; and this increased somatic activity had a boomerang effect on the affective state, producing emotionally overdetermined imagery and behaviour patterns. In the human organism there was a constant autonomic irradiation, and whether this produced a psychosomatic illness depended not only on the nature and intensity of the stimuli but also on the state of the organism itself. The basic constitutional types that he had described[5] differed in their liability to develop illness in reponse-to stress; the athletics tended to have specific vasomotor reactions and they suffered from cerebral arteriosclerosis about three times as commonly as did the pyknics, in whom the incidence of hyperpiesia was above average. A multidimensional approach was necessary; one must consider the meaning of an organic disease and seek to understand the symbolism behind a symptom. Psychotherapy was applicable in syndromes that were complex-determined, and in syndromes in which a definite complex could not be discovered but which were accompanied by generalised intrapsychic tension. Morbid syndromes not of psychogenic origin were also benefited by the easing of tension from psychotherapy.

Professor Kretschmer remarked that at his clinic the methods were based largely on the work of Schultz[6] and Jacobson[7] and Yoga. The therapist acted as instructor or trainer, and the patient was encouraged to take an active part in his treatment. "Fractional hypnosis" was employed to aid in the regulation of tonus by a series of conditioned reflexes. This was accompanied, in the purely psychological sphere, by an analysis of the patient's current problems; the resulting insight could be employed didactically in the form of "maxims" during the hypnoid state, or else pure suggestion could be used to overcome symptoms which persisted after their dynamic causes had been removed. The aim of the induced tonus regulation was to loosen up the patient in every sphere. This could relieve or cure numerous organic diseases that were associated with autonomic or endocrine disequilibrium. Therapeutic nihilism resulted from regarding morbid pathology as an accurate reflection of the pathological process in the living individual; by relieving vasomotor spasm, for instance, psychotherapy might not only relieve functional disorder but liberate healing impulses that could modify structural changes. In bodily illness, then, should psychotherapy or general methods first be tried? The answer was: whichever was thought more likely to cure that particular case. Where there was doubt the organic methods should usually be tried first since these were less time-consuming, but in some cases the converse applied. The too organically minded physician and the too psychogenically minded psychotherapist should each reconsider his position.

Dr. W. Sargant also spoke of the necessity for carefully selecting the cases for a particular method of treatment; if a treatment was extended to cases outside its scope it became discredited. He himself was asking the neurosurgeons to perform a very anterior leucotomy for certain psychosomatic or organic disorders, and was getting some promising results; for in certain cases of rheumatism, skin disease, cardiac neurosis, and cardiovascular disease, relief of the mental tension often improved not only the patient's affective state but the actual symptom itself.

Describing his system of "autogenic training," Prof. J. H. Schultz, of Berlin, said that this derived directly from hypnosis and auto-hypnosis and from Yoga. Basically it consisted of six series of exercises; first, progressive relaxation of the voluntary musculature, beginning with one arm ("weight exercises"); secondly, progressive relaxation of the blood-vessels, which are brought under voluntary control ("warmth exercises"); then training in voluntary control of the nervous regulation of the heart, of respiration, of the abdominal viscera, and of certain cerebral functions not normally under voluntary control. The results of training could be demonstrated thermometrically and by alterations in chronaxie. His methods had been used in Germany and North West Europe for the past twenty years, and it had been estimated that 50% of all functional dystonias responded to this training.

Sir HORACE EVANS, F.R.C.P., and Sir JAMES PATERSON ROSS, F.R.C.S., will be in attendance on the King during his Australian tour next year.

CHEST PHYSICIAN, EDGWARE , FORMERLY CHEST PHYSICIAN, HARROW

The decision of the Ministry of Health to allow B C G vaccination to be used in this country has been hailed as a great step forward in the drive to prevent tuberculosis So far we have not yet implemented a scheme for B C G vaccination, and the opportunity has been taken to review the efficacy of the preventive measures at present in force, so that some idea may be obtained of the benefits likely to result from the use of the vaccine in the area served by the Harrow clinic The figures here cited are derived from an area which is residential and densely populated—a typical dormitory The vital statistics are favourable compared with national rates

The general measures used for the prevention of tuberculosis have comprised education of the patient, rehousing, and supervision of contacts, especially children The first two measures are well known as potent methods of reducing the spread of tuberculosis Education of the patients is undertaken mainly by the chest clinics' health visitors Instruction is given in the patient's own home, so that all adult members of the family are aware of what should be done As regards housing, one out of every six new houses is allocated to the medical officer of health for the rehousing of tuberculous families on medical grounds

TABLE I—TUBERCULIN STATE OF 818 CHILD CONTACTS WHEN FIRST SEEN AND OF 783 NON CONTACTS

Age (yr)	Index case bacteriologically positive		Index case bacteriologically negative		Non contacts	
	No tested	No positive	No tested	No positive	No tested	No positive
Less than 1	67	4 (6%)	45	1 (2%)	10	0
1 +	47	7 (15%)	33	1 (3%)	7	0
2 +	43	15 (35%)	31	2 (6%)	9	0
3 +	51	15 (29%)	28	5 (18%)	14	0
4 +	45	18 (40%)	23	1 (4%)	12	0
5 +	39	16 (41%)	16	4 (25%)	41	0
6 +	30	15 (50%)	21	5 (24%)	25	2 (8%)
7 +	38	17 (45%)	20	4 (20%)	27	0
8 +	39	14 (36%)	13	3 (23%)	13	0
9 +	30	16 (53%)	15	3 (20%)	13	0
10–15	89	51 (57%)	55	5 (9%)	612	89 (14%)
Total	518	188 (36%)	300	34 (11%)	783	91 (11%)

CONTACT EXAMINATION

The examination of contacts is a time consuming procedure, and a considerable part of the health visitors' time is spent in persuading contacts to attend for their follow up examinations After the first two years the attendances of contacts seen previously drop sharply

For each case notified an average of four contacts, adults and children, have been examined in a search for sources of infection and for any damage done by the notified case We here present the results of examining 818 child contacts (under the age of fifteen when first seen) who have been tuberculin tested and followed up for various periods

TUBERCULIN TEST

The tuberculin test generally used has been the application of tuberculin diagnostic jelly (A & H) after rubbing vigorously with acetone until the skin is erythematous A large number of those over the age of ten have had a negative jelly test checked by an intradermal injection of 1 mg of Old Tuberculin The jelly test is accepted by us as being equivalent to the Mantoux test 0 1 mg in these age groups Of 255 children tested with both the diagnostic jelly and the intradermal tuberculin 0 1 mg , the results agreed in 232 In 10 the intradermal test was positive and the jelly test negative, while in 13 the intradermal test was negative and the jelly test positive These results are in agreement with Paterson (1944) and Dick (1950)

TABLE II—RELATIONSHIP OF CONTACTS TO THEIR INDEX CASE

Relationship	Mother	Father	Uncle	Aunt	Brother	Sister	Grandfather	Grandmother	Cousin
No tested	266	302	24	16	42	43	18	4	2
No positive	80 (30%)	103 (34%)	2 (8%)	3 (19%)	11 (26%)	15 (35%)	7 (39%)	1 (25%)	0

TUBERCULIN STATE ON FIRST EXAMINATION

Table I gives the reactions to tuberculin of the 818 contacts at this first examination according to whether the index case was positive or not to Ziehl Neelsen sputum smear or laryngeal swab culture Altogether 36% of the children in contact with a bacteriologically positive case were tuberculin positive when first seen, usually one to two weeks after diagnosis of the index case, whereas only 11% of those children in contact with bacteriologically negative cases were tuberculin positive This is identical with the percentage obtained on examining 783 non contacts in the same age groups

All the contacts included in this series were both domiciliary and familial contacts of the index case The relationship to the index case is shown in table II The risk of developing a positive tuberculin reaction from a parent was high, but there were no grounds for concluding that infection from either father or mother was more likely for a child of the same or the opposite sex Although the numbers were small, the great risk run by children in the same house as a grandparent with tuberculosis was apparent

Of the 222 children who were tuberculin positive when first examined 23 had definite tuberculous lesions—in the great majority of cases a Parrot Ghon focus

Of all the 818 children 3% (and 10% of those who were tuberculin positive) had a definite lesion The great

TABLE III—TUBERCULOUS LESIONS DISCOVERED AMONG 222 CONTACTS TUBERCULIN POSITIVE WHEN FIRST SEEN

—	Index case bacteriologically positive	Index case bacteriologically negative
Parrot Ghon focus	11	1
Collapsed lobe	3	—
Pleural effusion	4	—
Meningitis (fatal)	1	—
Miliary tuberculosis	1	—
Perihilar flare	0	2
Total	20	3

TABLE IV—PERIOD OF FOLLOW UP OF TUBERCULIN POSITIVE CHILDREN

Time of observation (yr)	½	1	2	3	4	5	More than 5
Index case positive	16	25	30	17	6	5	2
Index case converted	9	28	13	7	4	1	5
Index case negative	6	5	9	2	4	2	3
Total	31	58	52	26	14	8	10

majority of cases, as was to be expected, came from the children *in contact* with sputum-positive cases (table III)

FOLLOW UP

All the 818 children have been followed for various periods. For follow up purposes they have been divided according to whether the index case was persistently bacteriologically positive, bacteriologically negative, or bacteriologically converted—i e, the sputum and laryngeal swab became negative as a result of treatment The average period of follow-up for these groups was as follows

Index case negative		
Children tuberculin negative	476 child years	(average 1 8 yr)
Children tuberculin positive	55	2 7
Index case converted		
Children tuberculin negative	365	2 3
Children tuberculin positive	145	2 1
Index case persistently positive		
Children tuberculin negative	372	1 8
Children tuberculin positive	280	2 7

POSITIVE REACTORS

Table IV shows in more detail the number in each group of tuberculin positive contacts who have been followed up The period of observation starts from the date of first examination and ends on the date last seen for those remaining normal throughout, but on the date of the first abnormal film for others The time is given in completed years, hence a child observed for two years and nine months is recorded as having been observed for two years

Altogether 4 children who were tuberculin-positive when first seen have developed lesions (one was in contact with a sputum negative case, and the others with cases which were persistently sputum positive)

TABLE V—FOLLOW UP OF TUBERCULIN NEGATIVE CHILDREN SHOWING THE NUMBER WHO UNDERWENT TUBERCULIN CONVERSION

Time of observation (yr)	½		1		2		3		4		5		More than 5	
Index case positive														
Total	46		54		27		14		13		9		7	
No converted		21		13		7		4		6		5		1
Index case converted														
Total	16		52		39		22		12		9		9	
No converted		2		9		2		—		2		4		–
Index case negative														
Total	54		85		64		37		14		9		3	
No converted		12		3		6		2		1		1		–
Total	116	35	191	25	130	15	73	6	39	9	27	10	19	1

(1) Male aged 2 years, developed a temporary collapse of the left upper lobe two years later

(2) Male aged 10 developed bilateral pleural effusion six months later

(3) Female aged 1, developed meningitis a year later and recovered. No lesion had been detected previously

(4) Male aged 6 developed a transient collapse of the right middle lobe after two years observation.

Thus of the group of children tuberculin positive on first examination, by far the greater number (98%) did not develop a lesion even when in continued contact with a case of pulmonary tuberculosis whose sputum was persistently positive

NEGATIVE REACTORS

The 596 children who were tuberculin-negative on first examination have all been followed up for at least six months Table V shows in more detail the number of tuberculin-negative children who have been followed up and the interval before tuberculin conversion took place. The intervals stated are in completed years of observation, as for the tuberculin positive children, the period of observation being here regarded as terminating as soon as tuberculin conversion took place Altogether 101 tuberculin conversions were observed The largest number were in children in contact with persistently positive index cases, as would be expected However, the number of conversions among the contacts of *apparently negative cases shows how poor are our* methods of detecting tubercle bacilli in the sputum of patients

It is surprising how long children can remain in contact with a persistently sputum-positive relative without tuberculin conversion occurring There were 23 children, under one year of age on first examination, in contact with a *persistently sputum positive parent*, and yet after six months there had been only 4 conversions (table VI)

TABLE VI—*TUBERCULIN NEGATIVE CHILDREN UNDER ONE* YEAR OF AGE WHEN FIRST SEEN IN CONTACT WITH POSITIVE INDEX CASE

Period observed (yr)	½	1	2	3	4
Number of children	23	16	11	2	2
Number of conversions	4	2	3	0	1

The relation to the index case was as follows mother 10, father 9, uncle 2, aunt 1, and sister 1

The social conditions in the homes of these 23 children were analysed by the appropriate health visitors as follows

Good	15 cases,	2 conversions
Fair	4 „	1 „
Poor	4 „	1 „

This avoidance of infection in the home is paralleled in experiments on animals Calmette (1936) showed how difficult it is to infect even the guineapig experimentally by inhalation Very rarely did infection occur even when the guineapigs were kept in the same room as a tuberculous patient expectorating up to 7000 million bacilli a day Calmette ascribed this to the large diameter (100–500 μ) of the droplets expectorated, this made them fall quickly to the ground He postulated that infection only takes place by coughing directly in front of a child

The lesions associated with tuberculin conversion were analysed All these cases were followed up by X ray films and screening for at least six months after conversion, and any lesion found in that period was counted as a lesion accompanying tuberculin conversion Occasionally a primary focus was not visible at first but became visible during the following months

INDEX CASE PERSISTENTLY POSITIVE

57 conversions occurred among the 170 children in this group, the time interval for this being given in table VII

The lesions found on tuberculin conversion or within six months of its occurrence were as follows

None	42 children
Parrot-Ghon focus	8 „
Hilar enlargement	4 „
Meningitis	1 „
Collapsed lobe with cavity	1 „

Thus 14 children, during the period of observation, developed lesions, 1 child who had no lesion on conversion, developed tuberculosis of the adult type four years later, 1 with a Parrot Ghon focus developed a tuberculous hip six months later, and 2 with hilar enlargement developed a collapsed lobe later

INDEX CASE BACTERIOLOGICALLY CONVERTED

There were 19 conversions in this group (table VII), 3 of these children developed a Parrot Ghon focus, and in the remaining 16 children no lesion was detected

INDEX CASE BACTERIOLOGICALLY NEGATIVE

There were 25 conversions followed up in this group (table VII), 1 child developed meningitis on conversion, and in the remaining 24 children no lesion developed

TABLE VII—FOLLOW UP OF CONTACTS AFTER TUBERCULIN CONVERSION

Period followed after conversion (yr)	½	1	2	More than 2
Index case positive	8	29	9	11
Index case converted	8	5	5	1
Index case negative	13	7	5	—

As would be expected, the greatest number of lesions found when tuberculin conversion took place was in those children in contact with patients with a persistently positive sputum

The number of children who developed lesions while under continued observation was 19, whereas a lesion was already present in 23 on first examination Thus the greatest damage had been done among the child contacts by the time the index case was diagnosed

B C G VACCINATION

It is important to remember that among 101 tuberculin conversions only 18 lesions were discovered, and most of these were radiological findings of no very serious significance, requiring observation and supervision but seldom treatment Only 1 death occurred It is true that tuberculous infection in children can become a tragedy, and that about half the deaths in childhood are due to tuberculosis, but this high incidence is largely due to the small total number of deaths in this age group The danger of a natural infection is likely to be due to the uncontrolled dose of bacilli so received, B C G is alleged to be a method of causing infection with a controlled dose of innocuous organisms

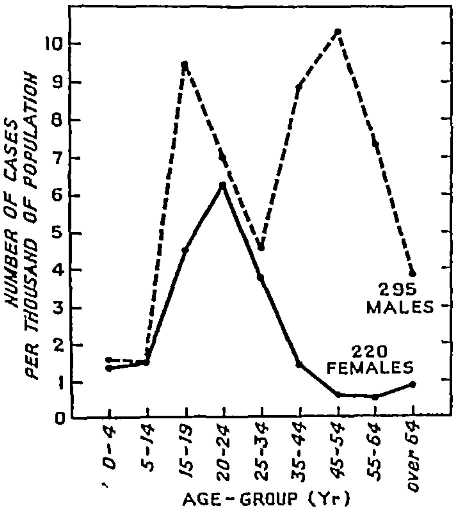

Fig 1—Age-distribution of 295 male and 220 female notifications of tuberculosis

If all the 596 children who were tuberculin negative on first examination had been vaccinated with B C G, and if this vaccine is fully effective, only 18 cases of disease would have been prevented, and these cases were spread over five years It can therefore be seen that the use of B C G in child contacts is not likely to reduce the incidence of tuberculosis very much

It must also be borne in mind that vaccination with B C G is likely to lead to a sense of security in the patient's family, with a consequent reduction in the care taken over the general measures of prevention of infection

If B C G vaccination is to be used most effectively it must be used in other ways than only among nurses, medical students, and contacts of known cases The work of the mass miniature radiography units has shown us that there is at least one sputum positive ambulant undiagnosed case per thousand of population The damage done by these undiagnosed cases has been assessed by analysing 104 consecutive notifications of children received by the medical officer of health

No contact with a known case, and no source for the infection found	66 (63%)
No contact with a known case, but source found on examining contacts	10 (10%)
Diagnosed at first attendance as a contact	16 (15%)
Disease developed after contact broken by removal of the infectious case	9 (9%)
Children in continual contact with a known case	3 (3%)
Total	104

It can be seen that in 63% of cases no source for the infection was found in domiciliary or familial contacts

Fig 1 shows the age distribution of 295 males and 220 females notified during the eighteen months from January, 1949, to June, 1950, in the urban district of Harrow, given as the incidence per thousand of population It will be seen that there is a big jump in the number of cases in the age group 15–25 Fig 2 shows the percentage of 933 non contacts who were found to be tuberculin positive Most of the non contacts between the ages of 11 and 18 were obtained from examining the pupils in a grammar school There is a great jump in the percentage of positive reactors to tuberculin immediately on leaving school, and this recent infection in this group is probably the cause of the large number of cases of tuberculosis found in the 15–25 age group (Wallgren 1948) and results from infection from unknown sputum positive cases of tuberculosis in our midst A reduction in incidence of tuberculosis is only to be hoped for if the effect of infection in this group can be minimised, and it seems that the best use of B C G is to vaccinate all school leavers

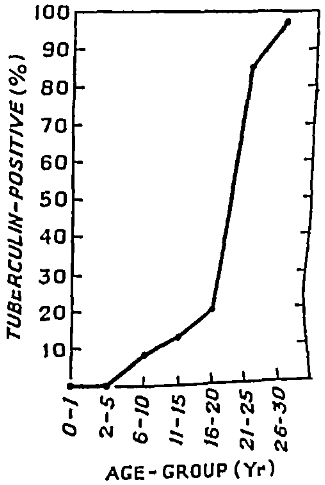

Fig 2—Percentage of non-contacts tuberculin-positive in various age-groups

SUMMARY

The findings are given of routine tuberculin testing of 818 child contacts, of whom 222 were positive when first seen

The results of 101 tuberculin conversions are analysed

In the whole series there was only 1 death

Arguments are produced favouring the use of B C G in school leavers as most likely to reduce the present high incidence of tuberculosis

We are most grateful for the invaluable assistance given by Miss E M Jewell

OFFICE MANNERS *

G P HARDY ROBERTS
C B , C B E
SECRETARY SUPERINTENDENT THE MIDDLESEX HOSPITAL

VERY few things can be done well without taking thought and trouble That is my excuse for speaking to you about matters which may seem too elementary to deserve attention

A hospital administrator has to do much of his work his office, and his time there is mainly taken up with nterviews, correspondence, telephone conversations, and onferences , and yet how little is said about these things n the average course of instruction in administration

The importance of this side of his work is the greater you accept my view that the chief administrative fficer should delegate all routine duties to his colleagues nd so leave himself free to deal with the so called minor roblems, which are numerous, and the matters of major olicy, which are few If his office is the place to which enior administrative officers can come for advice about heir work, junior officers for help over personal problems, patients with complaints, medical staff with requests of various kinds , if every inquiry by letter or telephone which does not " belong " to any department is brought to him—you may agree that skill and care over interviews and letters call for some consideration

Before we go any further let me say that it is easy to talk about these things and to suggest the right line to take For my part, I should not like to confess how often I fail to observe the following simple code

INTERVIEWS

It is a good plan to be accessible to everyone Don't let your secretary become your gaoler, insist that she arranges an interview for everyone who wants to see you You will find that few people will abuse the privilege , those who do can be dealt with appropriately

A small amount of " stage management " is worth while, especially when you are to see someone from outside the hospital Your secretary should put ready such papers as may be needed , and if it seems likely that you will have to consult any of your colleagues, while the interview is in progress, she should see that they are " on call " Let your desk be clear of all other papers and files

Decide, before your visitor comes in, how long you can spare for the interview , and have a small clock on your desk in line with your visitor's chair so that you can keep it in view without it being obvious to him Remember that almost any interview will be a failure if you give the impression of being short of time The purpose of the average caller is to get something off his chest , so, unless he wanders from the point, it is best to let him have his say, before you begin Avoid any appearance of hurrying him, give him your entire attention, and let nothing seem to distract you The telephone should be switched through to your secretary, so that she can take the calls (There are few things more irritating than trying to talk to someone who is forever turning away to speak on the telephone) If there is an urgent message for you, she should write it down and bring it in unobtrusively, so that you can glance at it, when it is your turn to speak, and not while your visitor is leading up to his peroration

I suggest that the more timid and diffident your visitor, the more important it is to observe these rules Whatever the outcome of the interview may be, there is a good chance that he will leave your office feeling that he has had " his money's worth," even if he has not had his way

CORRESPONDENCE

The chief complaint of people who write letters to public bodies, Government departments, and so forth, is that they have to wait a long time for an answer, and that, when it comes, it is often hard to understand

Where possible all letters should be answered the day they arrive This is not so difficult to achieve if you take care never to have a " pending " tray in your office Letters from members of the public, if the required answer cannot be given at once, should be acknowledged politely (and that does not mean sending a printed card) within forty eight hours of receiving them

Things go wrong, even in the best hospitals , so from time to time you will get letters of complaint Some of these letters may be couched in abusive terms, and you will be tempted to write a biting rejoinder By all means do so (if it relieves your feelings) but consign it to the waste paper basket, and send in its place a courteous reply If the hospital is at fault, admit it and apologise , if the allegation is false, deny it, as firmly as you like, but as politely as possible It is always a mistake to have a row on paper We all know a few fortunate people whose charm of manner allows them to get away with quite outrageous remarks in the course of conversation But no-one can do that in a letter The letters which go out from your office should be dignified, without being pompous or unfriendly , they should be clear, concise, and to the point

Don't be intimidated by your secretary Very few people can dictate a perfect letter straight off, if the subject is a difficult one Dictate a draft to begin with , then work on the draft, taking out long words and turning complicated sentences into simple ones Never sign a badly written letter to save your secretary trouble , it is much better that she should be inconvenienced than that your letter should give offence or be misunderstood If she is the right kind of secretary, she will agree with this

TELEPHONES

The Hollywood version of the high powered executive, barking orders into a battery of telephones, is not one that I commend to you In my view, the telephone is a rather dangerous instrument, useful mainly in emergencies, or for getting the answer to a simple question When it is a matter of enlisting people's help, or of giving them detailed instructions, it is nearly always more satisfactory to see them personally When it is necessary to give a rebuke to a junior officer, it is nearly always unwise to use the telephone, because you won't know whether he is grinning impenitently or in floods of tears Above all, do not tell the switch board to put you through to someone and then keep him waiting on the line before you pick up your receiver Hardly anyone can avoid feeling cross when this is done to him

CONFERENCES

You cannot draw a line through a hospital and say that all on this side is medical, and all on that, administrative , there is a measure of integration at most levels Consequently, many of the problems that will confront you will consist in the need to provide the administrative requirements of experts in technical matters, which are beyond the range of the ordinary layman's knowledge

This is quite good for the soul of the administrator, and gives him a proper sense of humility But it need not depress you to the extent of feeling that you will be so blinded by science as to be unable to serve the expert in an administrative capacity If you show yourself to be a willing and interested listener, he can usually be persuaded to explain his problem to you in simple

---

* An address given to trainees in hospital administration

language I have used the word "expert" instead of "specialist" or "clinician," because these technical matters will derive not only from the medical departments, they will relate to engineering, nursing, finance, catering, and so on

There is no need to have an intimate knowledge of these subjects, but to be prepared to examine them from a common sense administrative angle To do this it is necessary to confer with the people who have first hand knowledge of the subject, be they professors or plumbers, ward sisters or consultants, architects or cooks Never be too busy in your office, or outside it, to listen to and question the men and women who are experts in their own line The administrator who "thinks he knows," and acts without advice, is a danger to any organisation The wise administrator will not try to conceal his ignorance, he will have the good manners and the good sense to confer with the experts, and to ask them to "vet" his plans and instructions before he puts them into effect

Lose no opportunity for conferring with the matron At a teaching hospital, in particular, she has a large command and a great responsibility, and it is essential that she and the chief administrator should march in step This cannot happen if you exclude her from all administrative matters, except those directly concerned with nursing It is better to bring her in on every problem in which she is likely to be interested, and you will find that there are many in which it is valuable to you to have her advice and help

Remember, too, that the man at the Ministry who signs himself "your obedient servant," and seems such an alarming bureaucrat, will usually prove to be a human and helpful colleague, when you have had an off the record talk with him in your office, over lunch or a cup of tea In my view, this sort of conference is often of greater value than the more formal kind in big committee rooms, and can save an amount of official letters

There is a type of senior executive who seeks to emphasise his own importance by keeping as much information as possible "under his hat" You will find that very little of your work is confidential For the rest, you will make the task of your colleagues and principal subordinates easier and more interesting if you keep them in the picture about your actions and plans Let your office be an information bureau rather than a miniature Kremlin

LOOKING FOR TROUBLE

One of the best things to do with your office is to leave it—for an hour or two every day However much work you may have on hand, however deeply submerged you may be in official memoranda and circulars, you should get out and about the hospital, and see things for yourself It is a mistake to get office bound

I am not suggesting that you should be a "snooper" On the contrary, I think it is better to make your visits to wards and departments at regular intervals, accompanied by the matron or the head of the department concerned Ward sisters and others will then know the day on which you come to see them, and will get the habit of producing their problems and difficulties to discuss with you It is no good persuading yourself that these things will be brought to your notice in your office, that will only happen with the more important ones, and usually too late If you want trouble (and you should be a glutton for trouble) you must go and look for it Having found it, you must do something about it, otherwise people will decide that it is not worth their while to tell you things

THE RÔLE OF THE ADMINISTRATOR

My last bit of advice is to avoid the mortal sin of administration—the belief that the tail can wag the dog In these days, finance comes into everything, and management has become very complicated In these things, it is our duty to advise the board of governors and to give effect to their decisions Many of their more important decisions relate to medical matters, and it is very easy for the chief administrative officer to misuse his influence with the board, and to obstruct the projects of the medical committee Where this happens, or even seems to happen, the seed is sown of dissension between doctor and administrator, and the plight of the hospital is like that of an army whose commander is dominated by his quartermaster general

If we are wise, we shall remember that, in the war against disease, we are not front line troops Our role, and we can be proud of it, is to be of service to the medical and nursing staff More often than not, we can help only in small ways, by taking on the dull jobs, by being enthusiastic about other people's plans, by being heedless of our own rights and anxious about the needs and privileges of others The English saint of long ago might have been thinking of modern hospital administrators when she said

> "to yield is to command, to be unknown is to be celebrated, and work that seems of little use comes nearest to the working of miracles"

A MENTAL HOSPITAL IN BRITISH COLUMBIA

JOHN MOSS

C.B.E

WHEN I was in Canada last year, I visited the Provincial Mental Hospital at Essondale, British Columbia, which has accommodation for 3600 patients. This is in all respects a modern hospital with excellent facilities for clinical investigation, diagnosis, and treatment of all mental and neurological conditions In addition to medical and surgical facilities it provides all accepted forms of psychiatric therapy

EQUIPMENT AND ADMINISTRATION

The occupational therapy department, run on the lines of well developed units of the kind in our own mental hospitals, offers the choice of a wide range of interesting crafts Recreation and play are organised by a recreational director, for it is argued that if recreation is necessary for a well balanced life in the case of normal persons, it is even more necessary for mental patients A golf course of 8 holes has been laid out with very good greens, and there are both grass and hard tennis courts Summer dances are held on the hard courts and have been attended by as many as 1200 patients at one time Among other sports and pastimes provided are archery (with regulation targets, and standard strength of bows equipped with steel tipped arrows), "housey housey" gatherings, variety parties, concerts, bands, inter ward cribbage, checker and chess tournaments, crossword and cryptogram contests, quiz shows, picnics, horseshoe pitching, music appreciation, and club swinging, and field and sports days Patients are encouraged to organise their own sports activities

The buildings are scattered over a large estate, and the grounds have been beautifully laid out as a park by an expert from Kew Gardens This park is freely open to the public, who are encouraged to picnic there at week ends, and who often drive out there to spend a few hours in the open air This is a way—and a good way—of teaching people that mental hospitals are not places to be dreaded On public holidays, I was told, hundreds of people come and wander round the grounds

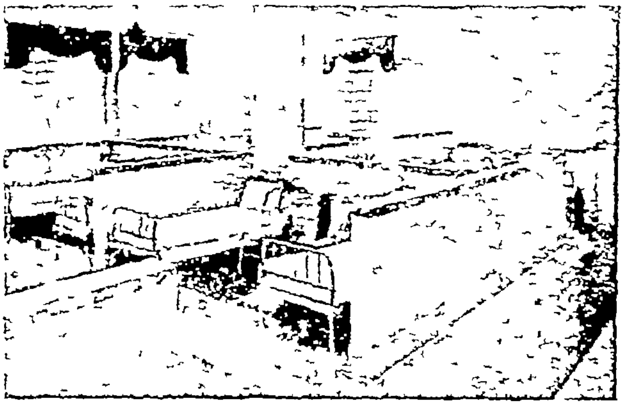
Admission to the mental hospital is broadly on the same basis as in England Some patients are certified but there is a steady increase of those who seek admission as voluntary patients As in this country difficulty has been caused in mental hospitals in Canada through the admission of elderly senile patients who are accepted because there is no other suitable accommodation for them No person over the age of 70 can be received at Essondale without the special approval of the medical superintendent, but he has to accept a large number because no other care may be available for them One major difference between the administration of this mental hospital and similar hospitals in Great Britain is that there is no local committee The medical superintendent is responsible to the Provincial Department of Welfare, for all matters connected with administration, but there is also a business manager who is responsible to the medical superintendent for the general running of the establishment, I was told that in practice he has a free hand since it is considered that the general administration is better undertaken by a lay specialist

STAGES OF TREATMENT

Treatment in the hospital may be divided into early and active treatment of the acutely mentally ill with a view to early recovery and rehabilitation, and continued treatment for those patients who require treatment for a long time The social service department of the hospital works closely with both classes of patients and the staff of the psychiatric department visit the homes of all patients admitted from local areas There are ten psychiatric social workers on the staff, and they supply detailed accounts of the patient's life and circumstances to the psychiatrist, so that he is fully informed of the factors contributing to the mental illness Visits in other areas of the Province are made by the Field Welfare Service, which undertakes general welfare work. The officers of this service are social welfare workers without a psychiatric qualification. While the patient is in hospital one of the psychiatric social workers keeps in touch with him and with his home Rehabilitation plans are worked out between the psychiatrist and the psychiatric social worker and supervision is continued for six months after a patient's discharge To carry the rehabilitation of women patients further, a small communal home has been established in Vancouver where a recovered patient may, if necessary, live a normal unrestricted life until she is able to find employment and be self supporting

THE CLINIC

In the hospital grounds, at some distance from the main building, a fine new building for 325 patients has been erected as a clinic of psychological medicine, and as a teaching unit in the new faculty of medicine in the University of British Columbia, at Vancouver The building is most luxurious, both the construction and furnishing being as good as would be found in any high-class hotel. There has apparently been no public criticism of the expenditure This is a new development in Canada, and I was told that even the United States have no counterpart on the same scale The clinic is a teaching centre, and provides active treatment for those patients suffering from early mental illness whose recovery and rehabilitation may be anticipated within four months This is felt to be a distinct advance beyond the usual mental hospital type of treatment, being a step closer to community and general hospital types of care The clinic houses a group of specialties representing all branches of medicine surgery, and psychiatry The X ray department is fully equipped for radiology, and also has an operating theatre and special apparatus for cranial and brain studies The clinical laboratories can undertake all types of investigation, and the staff are also engaged in teaching and research The department of cardiology has the means for full study of the heart and cardiovascular system, and for the determination of the basal metabolic rate, the neurological department undertakes electro encephalography, and there are also a well equipped department of physiotherapy and an ear, nose, and throat department The department of occupational therapy and the recreational department have already been mentioned A special Act of the Provincial legislature provides for the admission of voluntary patients to the clinic, but patients may also be admitted on the certificate of two medical practitioners (no legal certification is required) The maximum period during which any patient may be retained at the clinic is four months, after which he must be transferred to the main building if he requires further care Those responsible for the scheme believe that this intensive approach to the treatment of mental illness will bring psychiatry close to other branches of medicine and will do much to gain the confidence of the population in seeking early advice in such matters It is hoped also that it will do much to place mental illness on the same plane as physical illness and help to remove any stigma which uninformed people may have regarding sickness of the mind



The old people's dormitory

HOMES FOR THE AGED

In the same grounds as the mental hospital, but again at some distance and not visible from the main building are two storey buildings which have been erected to meet the needs of elderly patients A special feature of these buildings is the provision of ramps instead of staircases from the ground floor to the first floor The grade of the ramp is such that it permits comfortable walking as well as the use of wheel chairs and stretchers The front entrance is also ramped, and leads to spacious lawns for outdoor activities All floor space, including the ramps, is indirectly lighted at floor level, so that the old people can easily see their way, and all the ramps and corridors are provided with handrails

In Canada, as in this country, a major problem is caused by the ageing population and this is due, it is considered, very largely to advances in medical and surgical care which are increasing the average life span Provision of new institutions or old people's homes to replace the out of date poor law buildings, still to be found in many parts of Canada as in this country, is proceeding slowly, but the arrangements at Essondale are of rather a different type and seem well worth studying by those trying to relieve mental hospitals of some of their senile patients

Many applications for direct admission are received, but since the main purpose is to relieve the pressure on the mental hospital all admissions must be made through the hospital itself Like other patients, old people may be voluntary or certified If certified on admission to the main hospital, they remain certified on transfer to the home When the clinic is in full operation, elderly persons, like younger people, will be admitted to the clinic instead of the main building After treatment many of them, it is hoped, will be able to return to their own homes but those who need care for more than four months will be transferred to the residential home when they come to the end of their period of treatment in the clinic

The home is perhaps too large to give quite the same easy domestic atmosphere as the small type of residential home in which we have begun to specialise over here But it must be remembered that Essondale provides for elderly patients who would otherwise be in a mental hospital They could perhaps be classed as senile, although some of those I saw were in fact very little different from many of those to be found in institutions, and even old people's homes, in Great Britain The "institutional atmosphere" as we know it, however, had been very largely avoided There were several comparatively small—and very comfortable—sitting-rooms where the old people could divide up into small groups, and in the grounds I saw them in small companionable parties, reading or chatting together In the central dining room of each block they eat at small tables capable of seating four The food is cooked centrally and taken in containers to the kitchens of each block

The dormitories are broken by low partitions, as shown in the photograph, which give some privacy for either one or two old people, but also allow of adequate supervision I think this plan might be copied in erecting similar buildings in this country Bed-ridden patients are not normally taken in these blocks

The cost of maintenance is higher in the old people's home than in the mental hospital, where much of the domestic work is done by the patients themselves Most of the older patients in the home are incapable of doing any work There was a very friendly atmosphere about the place, and the relationship of the patients and the staff was excellent

NATIONAL HEALTH SERVICE TRIBUNAL

REMOVAL OF PRACTITIONER'S NAME FROM LIST

THE Minister of Health has issued a report of an inquiry held by the tribunal at Maidstone last August when the Complainant was the Kent and Canterbury Executive Council and the Respondent Dr Archibald Blair, of Strood, Rochester The tribunal consisted of Sir Reginald Sharpe, K C (chairman), Mr H Lesser (standing member), and Dr S A Winstanley (practitioner member) The Complainant alleged

(*a*) That, in breach of his terms of service, the Respondent had (i) neglected on Sept 28 and 29, 1949, to visit and treat one Betty Irene Smith, deceased, who was then his patient, when her condition required that he should so visit and treat her (ii) neglected on the said dates to render all proper and necessary treatment to the said deceased woman and (iii) on various dates between Aug 21, 1948, and May 12, 1949, failed to forward to the Complainant 775 records which he was required to forward

(*b*) That the neglect and failure aforesaid was the culmination of a series of earlier complaints of a similar nature against the Respondent, which complaints had been respectively substantiated in September, 1929, July, 1943, March, 1946, and July, 1946

The Respondent admitted the failure to forward the records But this part of the complaint was not pressed, and the tribunal did not pay any attention to it

THE FATAL ILLNESS

Dr Blair who is 55 has practised in Strood for 23 years—since 1940 without a partner On July 5, 1948, he had 3041 patients on his National Health Service list

On April 13, 1949, a daughter was born to the deceased woman (aged 26) and her husband Gunner Smith (aged 19) Dr Blair was not asked to attend either before, at or after the birth On Friday, Sept 23, 1949, when Gunner Smith arrived at his home on five days' leave he found his wife in good health and spirits, and she remained normal until about 4 45 P M on the following Wednesday, Sept 28, when she complained to her husband of pains in her right side About 6 P M the pains became more severe and (according to her husband) she "went rigid" Gunner Smith thereupon went and saw Dr Blair at his surgery and told him about his wife's pains, that she had that day eaten two ripe pears and an apple, and that her menstrual period was due Dr Blair gave Gunner Smith a prescription for mist kaolin, which the latter on his way home caused to be made up by a chemist. Gunner Smith reached home about 7 P M and gave his wife some of the medicine and also some hot water, which Dr Blair had also advised him to do According to Gunner Smith, Mrs Smith got progressively worse and kept fainting

At 2 30 A M on Thursday, Sept 29, Gunner Smith went out and telephoned to Dr Blair from a public call box (The main conflict of evidence arises over what he said.) Dr Blair did not visit Mrs Smith following upon this telephone conversation Gunner Smith returned home and continued to administer to his wife the medicine and hot water, as again directed Mrs Smith fell asleep and apparently died about 3 30 A M , she was lying on her right side with her knees drawn up Gunner Smith had already fallen asleep and it was not until he woke up at 8 20 A M that he was aware that she had died He at once went and saw Dr Blair at his surgery (just after 8 30 A M) and told him of the death

Dr Blair's morning surgery begins at 9 A M and lasts about an hour, so it was not till about 10 45 A M (on Sept 29) that he saw the body (Rigor mortis had by then set in.) He examined the body, such examination only occupied a few seconds consisting, as it did, in touching the eyeballs and a glance at the body to see if there were any signs of violence (which there were not) Dr Blair certified the cause of death as (*a*) cardiac failure and (*b*) myocardial degeneration

QUESTIONS OF FACT

In his evidence Dr Blair told the tribunal that he had had no doubt in his mind as to the cause of death and had had no hesitation in issuing the certificate which he did Though he was not expecting it, her sudden death did not surprise him, he saw no need for a post mortem examination, and it never occurred to him that it might be advisable to have an inquest He further stated that on a Saturday morning in September, 1949, the deceased had consulted him at his surgery, that he had then examined her and found that her heart was not sound He did not then (so he told the tribunal) form the opinion that she was likely to die at any moment, he gave her on that occasion a prescription for mist digitalis and advised her to have reasonable rest and not to overwork herself for some little time

"The Tribunal has had to decide whether or not the deceased did in fact consult the Respondent on a Saturday morning in September, 1949 It is highly improbable that the deceased would have consulted the Respondent on the first morning of her husband's leave without telling him about it, and the Tribunal can see no reason why Gunner Smith should have withheld from it such an important fact, if to his knowledge it actually happened The Tribunal sees no reason to consider Gunner Smith an untruthful witness, and it is satisfied by his evidence (which, incidentally, was not challenged on behalf of the Respondent on this point) that on the morning of Saturday, the 24th September, the first morning of his said five days' leave of absence, the deceased and her husband were turning out and scrubbing the floors of two of their bedrooms. It also seems very unlikely that the deceased would have joined her husband in the task of scrubbing if she had been advised by the Respondent a few days earlier (or at most a week or two earlier) to rest and not to overwork Nor is there any record to be found of any such visit by the deceased to the Respondent on any other Saturday morning in September 1949 Nor, indeed, is there any record of the Respondent having prescribed anything for the deceased on any occasion in 1949 except the mist kaolin on the 28th September, which was prescribed on the information given by her husband Secondly, another female patient of the name of Smith who was also on the Respondent's list, namely, Mrs Florence May Smith, had been under the care of the Respondent for heart trouble for a great number of years the Form E C 6 relating to her case shows that the Respondent did prescribe mist digitalis for her when she called at his surgery on the 26th September 1949 the Tribunal thinks it more than likely that recollecting that a Mrs. Smith had been to see him about her heart trouble on the 26th September, the Respondent when he discovered that a Mrs Smith had died, apparently from cardiac failure, on the 29th September, confused the two patients in his own mind and was under the mistaken belief that the deceased had been to his surgery a few days before her death. Either this confusion was never resolved in the Respondent's mind, or, if the Respondent did subsequently realise the mistake he had made, he decided that it would be better to keep to the story that the deceased had visited him about her heart shortly before her death ' Further evidence supported the idea that Dr Blair confused the two Mrs Smiths

Gunner Smith and his mother believe that Mrs Smith died of appendicitis Such an opinion cannot be reconciled with medical science Even the Doctor who was called as a witness on behalf of the Complainant did not think that appendicitis would kill in such a short time (that is to say from 4 45 P.M. one day to 3 30 A.M. the next day) Furthermore, there is no evidence that the cause of death was not cardiac failure indeed the Tribunal is upon the material available of the opinion that some *form of cardiac failure* was the cause of death. There does not however appear to the Tribunal to be any sufficient ground for saying, as the Respondent did, that the secondary cause of the death of this young woman of 26½ years of age was myocardial degeneration. Such a cause of death in a woman of that age would have been a matter of considerable clinical interest to her doctor Neither the deceased's mother in law nor her husband had any knowledge that the deceased suffered from any form of heart disease and, as the Tribunal has found the Respondent had not given the deceased advice concerning an ordered life

The Tribunal is clearly of the opinion that not only upon the facts as found by it but even upon the Respondent's own version of the facts the Respondent ought to have reported the death of the deceased to the Coroner

The Tribunal has some satisfaction in being able to place on record its unanimous opinion that the deceased did not die as a result of any negligence or lack of professional skill on the part of the Respondent The evidence adduced before the Tribunal has not indicated any failure on the part of the Respondent to give such treatment as might have saved the life of the deceased. The evidence indicates that the deceased died at 3 30 A.M. while the Respondent could not in any event have reached her until 3 A.M (or perhaps a few minutes before) since Gunner Smith did not telephone to the Respondent until 2 30 A.M. The Tribunal is unable to visualise any treatment which the Respondent could have given the deceased only half an hour (or at most thirty five or forty minutes) before her death which would have saved her life "

A BREACH OF THE TERMS OF SERVICE *

But a failure to visit a patient when called upon to do so may well be a breach, and possibly a serious breach, of the terms of service of a Medical Practitioner under the National Health Service notwithstanding that such failure to visit the patient has in no wise been detrimental to that patient's health and/or physical condition. In the opinion of the Tribunal a medical practitioner is by virtue of his terms of service, under an obligation to answer a night call by visiting the person to whom he is called if in all the circumstances of the case it would be reasonable to require him to do so notwithstanding the fact that he has formed the view that possibly no benefit can accrue to the patient as a result of his visit It may sometimes be difficult to say whether it would or would not be reasonable to require a practitioner to answer a night call by visiting the patient concerned The Tribunal is of the opinion that generally speaking when proceedings are taken before this Tribunal the burden is upon the Complainant of showing that it would have been reasonable for the practitioner to have visited the patient and, if a prima facie case of such reasonableness is made out by the Complainant then the burden shifts to the Respondent of showing that it would not have been reasonable to have required him to visit the patient

' Each case must of course depend upon its own facts and naturally a great deal will always turn upon what the practitioner knows already and or is told at the time when he is summoned, about the particular case in question. Hence the importance in the present case of the Tribunal's finding as already appearing that the deceased had not consulted the Respondent within the four weeks preceding her death. But of even greater importance is the view which the Tribunal has formed as to the terms in which he was asked to pay a visit to the deceased in the early hours of the morning of the day on which she died

' Put shortly Gunner Smith's version of his telephone conversation with the Respondent at about 2 30 A.M. on the 29th September, 1949 was this that he told the Respondent that the deceased was considerably worse (meaning, worse than when he had seen the Respondent at about 6 P.M the previous evening) and that she was writhing on the bed in pain and was fainting and he asked the Respondent to come and see the deceased there and then. To this request (according to Gunner Smith) the Respondent said that he could not go and see the deceased because he was not expected to work all night Gunner Smith then said he would not have rung up the Respondent if he had not thought it necessary to do so The Respondent refused to go and visit the deceased despite the repeated requests of Gunner Smith that he should do so

' The Respondent's version of this telephone conversation is, briefly this *that Gunner Smith told him that the deceased* was still in pain but did not say either that she was writhing in agony or that she was fainting, that he (the Respondent) asked if Gunner Smith wanted him to go and see her, to which the reply was No, Sir The Respondent thereupon asked why he had telephoned, to which Gunner Smith replied that he wanted a medical certificate to cover himself against his over staying his military leave of absence on account of his wife's condition. The Respondent told the Tribunal that this was not the first time that Gunner Smith had asked him for a medical certificate to cover himself against his over staying his military leave of absence (Gunner Smith admitted in cross-examination that he had made such a request on a previous occasion, and that on the present occasion he did also ask for a medical certificate for such purpose) The Respondent further said in evidence that he certainly expressed himself forcibly upon the telephone on this occasion, that he said he would go and see the deceased in the morning, and that Gunner Smith ought to come for his medical certificate in surgery hours According to the Respondent the only purpose of Gunner Smith in telephoning to him was (so far as could be judged by what he—Gunner Smith—said) to ask for the said medical certificate

The Tribunal's finding of fact, as between these two stories must be prefaced by this statement that it has seen no reason to think that Gunner Smith is not a truthful witness at any rate in regard to his evidence as to what he and the deceased did on the morning of the 24th September, 1949 while on the other hand it has found that the Respondent was an unreliable and untruthful witness when he said that the deceased consulted him one Saturday morning in September 1949 shortly before she died The Tribunal considers it highly improbable that the sole purpose of Gunner Smith in going out at 2 30 A.M to a public telephone call box was to ask for a medical certificate It may be thought a little surprising that he troubled to mention the medical certificate at all but the Tribunal is of opinion that it is not improbable that he might have added a request for such a certificate after he had made clear the real purpose of his telephone conversation (namely to ask the Respondent to visit the deceased at once) and had had his request refused. The Tribunal has unanimously come to the conclusion that Gunner Smith did tell the Respondent over the telephone some details about the deceased's worsened condition and did ask him to come and see her It finds it impossible to believe that if the Respondent had asked over the telephone (as he says he did) whether Gunner Smith wished him to visit the deceased, the latter would in the circumstances have replied in the negative '

In coming to this conclusion the Tribunal has not overlooked the evidence of the Respondent's wife who stated on oath that she heard the Respondent ask Gunner Smith over the telephone (and heard him repeat the question) whether he would like him to go out and visit the deceased. Nor has the Tribunal overlooked the evidence either of Marian Helen Offord (the Matron of a Nursing Home at Strood) or of Kathleen Rose Shorthouse (a State registered nurse employed as a District Nurse in Strood) that the Respondent does a considerable amount of night work (although the Respondent himself put the number of his night calls at only three a month, a figure which the Tribunal regards as very low indeed) and has always answered a night call made by them and visited the patient concerned

THE TRIBUNAL'S DECISION

"The question now remains was it reasonable to have required the Respondent to visit the deceased on the night in question when asked so to do ? The Tribunal is unanimously of the opinion that the Respondent ought to have visited the deceased and that he had no reasonable excuse for not so doing The Tribunal takes a very serious view of the Respondent's conduct in the present case, but might not, possibly, consider that, if this were an isolated instance of such a breach of his terms of service, it would be justified in coming to the conclusion that his continued inclusion in a Medical List would be so prejudicial But there are other allegations of a similar nature against the Respondent The Tribunal is unanimously of the opinion that when the Respondent's failure to visit the deceased in the present case is considered in the light of his three said previous failures to visit a patient it is impossible to say otherwise than that his continued inclusion in the Medical List of the Kent and Canterbury Executive Council would be prejudicial to the efficiency of the General Medical Services The Tribunal has necessarily come to this conclusion with very real regret, realising as it does that such a decision must, to all intents and purposes, mean the end of the Respondent's professional career, or at least its suspension for a considerable period, after which he would necessarily have great difficulty in achieving any worth while position in his profession But the Tribunal has felt that its duty compels it to arrive at the conclusion which it has done"

An appeal was made by Dr Blair against the tribunal's decision, but, after careful consideration of all the circumstances of the case, was dismissed by the Minister Dr Blair's name must accordingly not be included in future in any medical list until the tribunal or the Minister directs to the contrary

THE DENTAL BOARD

OPENING the last session of the sixth board on May 9, Dr E W Fish said that although the hazards of the Parliamentary time table had not yet permitted the introduction of a new Dentists Bill, it was at least unlikely that the seventh board would run its full course

This sixth board, Dr Fish recalled, had taken office four years ago at the beginning of a period of great expansion in the accepted functions of central government and shortly after the publication of the final report of the Teviot Committee This committee had recommended that an independent "Dental Council" should succeed the board, and Ministerial assurance had been given that a Bill would be introduced into Parliament to bring this change about He and his colleagues had therefore, during their term of office, been concerned, with the transfer of responsibility for existing commitments, and had been limited in the scope of their activity by having to avoid new commitments which might hamper their successors

During the last five years they had enjoyed cordial relations with the General Medical Council The council had undertaken a visitation of dental examinations and were even now revising their recommendations concerning the dental curriculum In both these enterprises they had shown sympathetic understanding of dental problems and had offered the board every opportunity of taking part in making plans and in carrying them out Dr Fish felt, however, that despite these helpful and friendly relations, it was clear that the Act of 1921 was out of date For instance, in carrying out the work of the committees the board had to call upon the advice of more practitioners than the Act permitted the profession to elect to the board Similarly, in revising the curriculum the council had thought fit to invite representatives of the academic body from the dental teaching schools to join them in their deliberations The National Health Service Acts had placed upon the dental profession responsibilities which more than ever required that it should be a self governing profession, responsible for its own standard of education, its own registration, and its own discipline To discharge these additional responsibilities provision must be made, Dr Fish affirmed, for a "General Dental Council" on which the profession was more widely represented, and whose membership would include those with special experience of the matters with which the new council would be called to deal

---

Medicine and the Law

Insanity and Intention

THE House of Lords in Crowther *v* Crowther (reported in the *Times* of May 10) met with an intriguing legal question and answered, in effect, "It depends" A wife sought divorce on the statutory ground of three years' desertion On the husband's side it was contended that, after two years' absence from her, he had been received into a mental hospital by virtue of an order under the Lunacy and Mental Treatment Acts Thereafter, it was argued, the period of desertion could not continue to run, a person who is *non compos mentis* cannot have the *animus deserendi*

Mr Justice Ormerod was obliged to decide against the wife in the trial court, he was bound by previous rulings of the Court of Appeal in the cases of Williams and Rushbrook, decided some eleven years ago The Court of Appeal could not vary its previous opinion, the House of Lords, however, was free to review the position The question was whether a spouse could be held guilty of desertion without cause, while suffering from such a degree of unsoundness of mind as justified detention under a reception order Some previous authority could be cited for the view that desertion, originating in a deliberate intention to desert, continued until brought to an end, and in Drew *v* Drew (1888), where the husband was sentenced to prison, it was held that the physical inability to terminate the desertion did not prevent its continuance On the other hand it has been decided that insanity may operate as the withdrawal of a client's authority to solicitors to proceed with litigation

Lord Porter solved the problem by saying that persons who are abnormal in some respects may be normal in others, evidence alone could answer the question in which category the individual should be placed If no evidence was called on the point, or if a petitioner failed to prove that the mental patient was capable of forming an intention, the court was not entitled to draw an inference of continued desertion from the intention revealed in periods either before or after certification The House of Lords has therefore sent the case back to the court of first instance in order that evidence, if available, may be received and a conclusion reached in the light of the principle enunciated

The problem thus seems not unlike that which arises where parties seek to upset a will on the ground of the testator's insanity One side will produce testimony of insane delusions, the other side will maintain that, in spite of the delusions (if any), he had at the moment of making his will a sound disposing mind The issue may not be wholly settled by medical evidence An older generation of lawyers will recall a famous case where a testator's will was witnessed by four medical practitioners, all of whom were called to give their opinion that he knew perfectly well what he was doing The will was nevertheless upset

In England Now

A Running Commentary by Peripatetic Correspondents

FACILIS descensus Averno! Idle musings in the bath lead rapidly to Dangerous Thoughts, the Circumcellion Heresy, and even Tito deviationism. I saw the pit that was yawning at my feet when I caught myself wondering whether 60 registrars and residents pullulating where previously only 6 pranced must inevitably make the service ten times as efficient.

It began with our maid's thumb going septic. She produced a fluctuant swelling in the ball of the thumb which, in my days of practice thirty years ago, would have meant a half-inch cut, complete relief, and cure in three days. What happens now? Reluctantly laying aside a razor-blade, I send her to her family doctor. He prescribes a kaolin poultice and invites her to see him again in three days' time unless it gets worse, when she can come back earlier. After a painful night, she goes back with a humble note from me suggesting that perhaps he might think fit to open it or arrange for it to be opened. He sends her to the big local general hospital, where she is given penicillin injections and attends twice daily for the next two days, after which, during an attempt to "remove some dead skin," there is a gush of pus and she comes back a different girl. But since the hole was made by accident it is too small, so she is still attending five days later for penicillin and having the thumb soaked and squeezed and kept warm with infra-red rays.

One must make every allowance for "What the patient says isn't evidence," but if this sort of thing is going on all over England it must be costing the country a pretty penny. Are students no longer taught to recognise fluctuant purulent swellings? Or are they taught never to open them? Or am I just an old fogey who is hopelessly out of date?

* * *

The waiting-room door was ajar and I heard one patient tell another "I always come here. The magazines are so good."

And talking of magazines, I suppose that, the cry of "Bring out your Dead!" has not been heard in England since the days of the plague, but in 1951, O Fellow Peripatetics, we have "Bring out your Junk!" instead. What a chance for us to make some real money. Yesterday, when my char told us she got 8s from a rag-and-bone merchant for a pile of national dailies our thoughts turned with a bang to my husband's old medical journals, piled ceiling high in the cellar. Since then it's been a race. Who'll get to the merchant first, he or I? Somehow we're not quite so ruthless with our *Lancets* as with the others—there are back numbers in every room in the house and on both sides of the bed. When I thought of a Spring hat and started to gather them together I found myself stopping to read the old peripatetic columns and I'm still surrounded by a sea of *Lancets* dating back to 1945. My eye has just been caught by a comment on the remuneration of G.P.s under the "proposed scheme." Sorry, fellow writers, your words of wit and wisdom are doomed. I'll be able to afford a hat with flowers on it.

* * *

What is the cause, other than incipient sleep, of head-nodding in one's audience? It would be an interesting field for study. Is it an effort on the part of the nodder to impress the speaker with his knowledge or attentiveness or with his open mind—his ability to be converted by such powerful logic as that of the speaker? Is it merely an attempt to show that he at least has listened while all the others are asleep, or that he at least is intelligent enough to follow the speaker's confused utterances? Or is it a sort of reflex, set in motion each time the speaker strikes a chord by saying something which the listener has heard before?

Nodders are rarely equipped with sufficient experience or knowledge to justify their hearty manifestations of approval. I suspect that investigation would show that the I.Q. of nodders is lower than in non-nodding controls.

* * *

I keep meaning to have something done about my recurrent sinusitis, but somehow I can never find time; the same goes for my plantar callosity. A colleague of mine has been carrying about a grumbling appendix for over a year, and another has worn elastic stockings for years because he cannot get round to having a Trendelenburg done on his varicose veins. If we were laymen, we would promptly demand proper medical attention—and probably a holiday at the taxpayers' expense to boot. Why don't we do the same? Are we just a bunch of suckers, or hard-working idealists who are too conscientious to take time off from the service of humanity, or masochists? If we had to decide we would probably say cynically that our experience has taught us not to expect much substantial improvement from the therapeutic efforts of our professional brethren.

* * *

Tired of waiting for a health centre and of trying to do 20th century practice in 19th-century premises, our firm has mortgaged its children's future and built itself a new surgery. It has cost the earth, but at last each of us has a separate room with running water (h. and c.), a trolley for drugs and dressings, an examination couch, and a telephone. No more of this sharing ("After you with the auriscope, old boy"). No more making shift. The youngest doctor, who modestly disclaims any ability to hear anything through a stethoscope anyway, has the front room nearest the traffic. Next comes her immediate senior, the ham in the sandwich, and finally senex ipse, the outer crust, right at the back, remote and inaccessible. No longer can the patients gate-crash. All must put their heads through the dispensary hatch and tell the receptionist what they want or whom they wish to see. In a comfortable waiting-room they must wait their turn. Already (we hope) our standards have improved 50%. Perhaps the nicest thing of all is that we shall hear no more of that infernal squeak from the old front door as patients come in or go out.

* * *

In the days when a pound was worth twenty shillings I went to the extravagance of buying two pairs of tortoise-shell spectacles, in case one met with an accident. The other day, feeling that I needed my eyes tested again, I thought I would have this done under the National Health Service. The examination was carefully and patiently carried out, and I felt confident that my sight would soon be greatly improved by the new lenses. It was at this point that the optician raised the question of frames. "I've already got two pairs of real tortoise-shell," I told him, "and I want the lenses fitted to them. They're old pals." "I'm afraid that can't be done," the optician replied, "and I would advise you to get this model at 12s. 6d. extra. Very similar, don't you think?" Seeing my embarrassment, he continued, "Tortoise-shell rims now cost about £6—only people with more money than sense can afford such things." I began to repeat, "I've already got two pairs ...," but I suddenly thought, "Be hanged to all this; I'll get these State affairs as a standby and go and get tested privately by someone who can use my good old blinkers." Whether I'll get satisfaction I do not know. What I do know is that I'm the proud possessor of £12 worth of spectacle frames that a generous State doesn't wish me to use; and that unless I dip into an already depleted pocket I shall soon, willy-nilly, join the growing ranks of the plastically standardised.

* * *

"M.R.C.V.S." writes: "My fellow peripatetic of May 12 (p. 1068) has grossly misrepresented the destination of the *Observer's* 'nose to tail procession of vesicles.' Owing to traffic conditions in Trafalgar Square the procession was so late in arriving that the clinical meeting which was to have been held at the Institute of Veterinary Psychiatry had to be abandoned. A short impromptu discussion was arranged instead, the subject being 'Therapeutic Anosmia.'"

From a consultant's letter: "Her childhood was happy. Her father died at the age of 4."

Cause and effect?

Letters to the Editor

COLONIC REPLACEMENT OF THE STOMACH

SIR,—Mr Moroney is to be congratulated on doing something to the stomach which has not been done before By excising a large part of that organ together with the ulcer and replacing the deficiency with transverse colon on 22 occasions, he has shown considerable operative skill Suture lines in colon leak more readily than in other parts of the gut, though less so in patients with benign lesions By including in his article (May 5) postoperative thoughts on pH, "dog's stomachs," and "mucus," he has also shown a capacity to rationalise

Though the operation may be featured in the Dome of Discovery in the next Festival of Britain, it may have to wait as long to see if it is worthy of the honour It has taken half a century to remove the rose coloured spectacles which Moynihan, with others, succeeded in placing over the eyes of British surgeons when he encouraged anastomosis of stomach to jejunum Now that the stomach remnant is once more creeping back to its natural exit, the duodenum, it seems a pity that it should have to be via the colon

I hope Mr Moroney, together with Mr Aylett,[1] whose recently announced operation appears from subsequent letters to have given violent indigestion alike to men and dogs long years ago, will both tell us more later, and that others will not rush to these new fields merely from the delight of their spring greenness

For those who would like to try something new to many but even older than Billroth II (Polya to most), I can recommend that they do just as Mr Moroney does, only leaving out the part about the colon The operation is best known as Billroth I This will require excision of the ulcer, and even in large adherent duodenal ulcers this is usually manageable with experience, patience, and mobilisation of the right side of the duodenum With adequate mobilisation of the greater curvature the customary amount of stomach can be taken and junction made without tension Only one suture line is required instead of three as in this new procedure Excision can be just as complete as with the Billroth II types The operation has eminent supporters, with their own variations of detail, including Grey Turner, Morley, McEvedy, Schumaker, and Walton in later years, and younger adherents include Hickey,[2] Franklin at Hammersmith, and Bohn at Reading (personal communications) My own practice is to use the Billroth I operation, at times for carcinoma, almost exclusively for gastric ulcers, and latterly predominantly for duodenal ulcers My cases have shown no fresh ulcers, but occasionally a small stomach syndrome for a few months which seems to right itself There have been no "efferent loop dumping," no "afferent loop stasis" with bilious regurgitation, and no stomal blockage This is no place for details, which I propose to announce later

Mr Moroney, by his pioneering, has added to our knowledge and opened up new fields, and I hope he is right about the transverse colon As it tolerates fæces, lower ileal contents directly as in right hemicolectomy, and urine, it should not be offended by mere pabulum The effect of long standing acidic corrosion is yet to be established To replace a total loss of stomach, the colon may serve as it can in total loss of bladder For gastric carcinoma the operation is likely to fill a "long standing gap" But we do not look forward to an aftermath of articles on both early and late complications in cases with benign lesions

Billroth used his gastroduodenostomy for carcinoma initially I hope Mr Moroney will try, now and then, a Billroth I for benign ulcers I wish him and his adherents (may they be few when early) good fortune, a long silence, and an ultimate loud report

C S F CHANGES WITH PNEUMO-ENCEPHALOGRAPHY

SIR,—We read with great interest Dr Bickerstaff's paper[1] on changes in the cerebrospinal fluid (C S F) produced by intrathecal insufflation of air

The changes described by him, which we can confirm, are usually accompanied by very interesting vegetative reactions, and notably by blood changes, which we have studied Lumbar insufflation provokes, after a short period of leucopenia, well marked neutrophil leucocytosis lasting some hours F Hoff and others concluded from this that there exists a cerebral vegetative centre regulating the blood picture, and Beer believes that this is in the diencephalon, near the nucleus paraventricularis By this hypothesis the leucocytosis following pneumoencephalography would be an expression of direct irritation of the centre

We found that lumbar air insufflation causes, besides leucocytosis, leukergy[2] Leukergy[3] consists in the clumping of white cells in citrated blood, immediately or after incubation at 37°C for 1–3 hours This reaction is a very sensitive test in febrile diseases and inflammatory processes, its degree can be expressed as percentage of clumped cells The cells tend mainly to form cytologically homogeneous groups—i e, one often sees separate groups of neutrophils, lymphocytes, and monocytes, with 3 to 20 or more cells in a single group Leukergy is a cellular, and not a humoral, phenomenon, for leukergic leucocytes transferred to normal plasma clump as in their own plasma, whereas normal leucocytes do not clump in an inflammatory plasma Heating to 46°C or transfer to a 2–4% solution of saline disintegrates the clumps The clumping is due to increased adhesiveness of the cells and to their random collisions. Experimentally leukergy can be induced by intravenous injection of killed gram negative bacteria or by intrapleural injection of turpentine The condition is associated with bone marrow irritation, evident in a shift to the left in the Arneth count, and the quantitative parallelism between the percentage of leukergic cells and the leucocytosis and shift in the Arneth count suggests that leukergic cells are newly released from the bone marrow

It may be assumed that these adhesive white cells, liberated in the presence of inflammation, have a special function, and there is some evidence that they have enhanced powers of migration, bacteria adhere to the clumps and platelets, thus favouring phagocytosis The development of leukergy after lumbar air insufflation can be rationally connected with the pleocytosis of the C S F Leucocytosis and leukergy after encephalography may be attributed to either (*a*) an inflammatory reaction to irritation of the arachnoid by the air, or (*b*) direct irritation of the supposed diencephalic blood regulating centre The first of these two explanations seems the more likely, for the cellular content of the C S F in the lumbar region rises actually during insufflation of the air, and the cells are mainly monocytes As to the second possibility, we repeated the classical experiment of Freund and Grafe in rabbits

We transected the spinal cord between the 7th cervical and the 1st dorsal segment—i e, below the spinal centre for innervation of the diaphragm and above the rami communicantes albi Hoff and Linhardt found no peripheral leucocytosis in such rabbits after injection of bacteria, and they concluded that a blood regulating centre existed. We, too, found that peripheral leucocytosis did not develop; but five hours after transection there was well marked leukergy, reflecting stimulation of the bone marrow which was also evident in marrow counts and increased leucopoiesis.

---

[1] Bickerstaff E R *Lancet* 1950 ii 683
[2] Stein W *Ann U M C S* 1949 4 553
[3] Fleck L *Sang* 1949 20 1

If there is a centre regulating the blood picture, either it is concerned only with the number of peripheral white cells (possibly by vasomotor innervation) or it acts at least partly by humoral mechanisms. After injection of bacteria, both in normal rabbits and in those submitted to transection of the cord, the number of circulating neutrophils rises and there is a shift to the left in the Arneth count; but in the animals with a transected cord the total number of leucocytes does not exceed the initial count. Rabbits deeply narcotised with Sodium amytal reacted in the same way as those with transection of the cord.

On the whole the existence of a distinct cerebral centre regulating the blood picture remains questionable. Undoubtedly the central nervous system influences blood morphology, but this influence is exerted rather through the many different vegetative functions; and after pneumo encephalography the C.S.F. pleocytosis is probably due to meningeal irritation.

LUDWIG FLECK
WIKTOR STEIN

OBTURATOR HERNIA

SIR,—In the following instance of the rare obturator hernia the patient was an African woman of middle age, a member of the Efik people of Southern Nigeria.

On admission to hospital on April 1, 1951 she had already been suffering for one week from complete constipation and frequent vomiting. Two days before admission a painful lump had appeared on the inner and upper part of her right thigh. She was a para 5 and gave no history of previous similar attacks of pain.

The patient was thin and in very poor condition when first seen. There was well marked visible peristalsis of the ladder pattern, but no abdominal tenderness or rigidity. The right thigh was partially flexed and externally rotated; all hip movements were painful. A soft, diffuse, and fluctuant swelling could be seen, extending 15 cm. down the thigh; it was of vague outline and had no cough impulse. Rectal examination revealed a ballooned rectum very tender on the right side.

Preoperatively strangulated obturator hernia with a ruptured sac was diagnosed; and operation was performed under spinal anæsthesia. Incision was first made over the swelling, which was found to consist of soft fæces lying free in the tissues deep to the pectineus muscle. A necrotic sac 1 cm. long, was seen in the region of the obturator foramen, but there was no recognisable intestine. A thin trickle of fæcal matter continued to come through the remnants of the sac. A lower abdominal approach was next made in order to examine the upper aspect of the hernia. The loops of intestine entering and leaving the hernial orifice were readily identified and there was no peritoneal infection. Both loops were firmly adherent to the orifice and a side to side anastomosis between loops above and below the obstruction was done. The thigh wound was left widely open and drained. The patient died on the third postoperative day in profound toxæmia.

This case conforms well to the usual features of obturator hernia, which is generally seen in multiparous women of poor physique and is often strangulated when first encountered. Preoperative diagnosis was made easier in this case by the presence of the large swelling in the thigh, although the Howship Romberg sign was absent. The double approach to the hernia from thigh and abdomen was an obvious necessity in this case.

It may interest young surgeons who are considering service abroad to know that recently in the course of ten days I operated on 8 cases of acute intestinal obstruction in this small country hospital. They included volvulus of small intestine due to peritoneal bands, intussusception due to a tumour of the ileum, fibrous stricture of the ileocæcal region, massive mesenteric hæmorrhage, agenesis of the rectum in a newborn child, obstruction and peritonitis following reduction en masse of a strangulated inguinal hernia, colic intussusception in a child, and the strangulated obturator hernia already described. This list should surely whet the appetite of anyone looking for experience in abdominal surgery. But he who would come to this type of work must be ready to rely solely on his clinical acumen for diagnosis, and to adapt his operative technique to the conditions of a plainly equipped theatre. Not for us are the ever more elaborate technical aids to medicine. In the volcanic age in which we live, however, such training may prove providential. And there is no doubt of the immediate good that will be done by any surgeon who decides to practise his art in this part of the world.

I wish to thank Dr H. Souster, acting medical superintendent, for permission to publish this case.

ASPIRATION OF EMPYEMA THORACIS

SIR,—Your annotation on the article by Dr Asher and Dr Davies (April 28) particularly concerns assessment of the value of penicillin administered intrapleurally.

I am encouraged to refer to my experience of the mechanical aspect of aspiration in pre antibiotic days. In my series of 558 cases of lobar pneumonia during the 1914–18 war,[1] I recorded 116 as complicated by empyema. Of these, only 30 underwent rib resection; the remaining 86 were treated by aspiration alone with satisfactory resolution. Whilst such a procedure might well be expected to clear up effusions in the early stage containing few pus cells, I was surprised by the efficacy of this simple treatment when, as in 60 instances, really thick pus was present. In 24 of these pneumococci or streptococci were identified.

Modern chemotherapy and the systemic and local employment of penicillin must surely be an encouragement to practise aspiration as a measure that may in itself be adequate, as well as a valuable preliminary when it becomes clear that to ensure complete drainage surgery is essential.

ADOLPHE ABRAHAMS

POLIOMYELITIS

SIR,—I should like to add the following experience to that recorded by Dr Harrington in your issue of May 5.

In each of the four cases of poliomyelitis encountered by me in 1947 the site of paralysis appeared to be related to trauma, as follows.

CASE 1.—Tonsillectomy followed a fortnight later by bulbar palsy.

CASE 2.—Injury to the left thumb, followed about a fortnight later by paralysis of the left forearm and shoulder. This man's wife had a two months' abortion at the same time as the acute disease that preceded his paralysis.

CASE 3.—Injury to left hand followed about a fortnight later by paralysis of the left arm.

CASE 4.—Impetigo of the left thigh, much scratched, followed by mild poliomyelitis with left quadriceps paresis. The time interval could not be assessed in this case because of the chronicity of the skin lesion.

At about the same time we encountered an old case of poliomyelitis which we regarded as belonging to the same series.

CASE 5.—A little later a girl aged 9 years attending for some other trouble, was found to have paralysis of the left arm and inquiry elicited the fact that paralysis had occurred about a fortnight after an injection of A.P.T. on Nov. 2, 1942.

This was our first encounter with post inoculation poliomyelitis, and we included it in the traumatic series. It was possible to trace most of the other children inoculated at the same time, and none of these had suffered ill effects from their inoculation.

AN UNUSUAL ASSOCIATION WITH TOBACCO

SIR,—In the following case smoking seems to have been the cause of an unusual syndrome

In 1926 a woman, aged 40, fainted while playing tennis On questioning she complained of severe pain between the eyes, her pulse was irregular, and she appeared to be so shocked that she was put to bed Within 24 hours the second and third toes of the right foot became painful, swollen, tender, and red, this condition gradually spread until it involved the whole foot and the leg to just below the knee, and the temperature reached 102°F The focal pain in the head gradually passed off after 24 hours, the leg lesion subsided, and after about 10 days the skin of the whole area desquamated the heart resumed its normal rhythm, and after about a fortnight the patient appeared to have recovered

A similar attack occurred 6 months later, and gradually attacks became more frequent until by 1941 they were taking place at intervals of little more than a month The patient was examined by a number of my colleagues, various diagnoses were made, including angioneurotic œdema, erysipelas, and an unusual manifestation of rheumatism After one attack she was put on salicylates, but these appeared to gravely increase the intensity of the attack X ray examination of the sinuses showed them to be clear, the frontal sinuses were small in development An aural specialist advised washing out the antrums to ascertain if there was any infection, but this was refused

I had noticed through the years that the attacks were related to exacerbations of a chronic bronchitis which the patient had had for some years, and these exacerbations seemed to be definitely related to smoking In 1941 I suggested that the smoking was responsible for the exacerbations of bronchitis and advised that the smoking should be stopped Accordingly it was reduced to two or three cigarettes per day, but this did not diminish the exacerbations, and further attacks affecting the foot and leg occurred with steadily increasing severity In 1943, when it was suggested that a surgical attack should be made on the sinuses, I advised that complete abstinence from smoking should first be tried

This was secured, and since that time no further attack affecting the foot and leg has been experienced, though the patient still has attacks of bronchitis whose severity increases at intervals

Birmingham J F BRAILSFORD

β-NAPHTHYL-DI-2-CHLORETHYLAMINE

SIR,—Reports on this substance in your columns[1][2] prompt me to relate briefly our experience with it in Italy, where the results obtained by Spigliati,[3][4] Introzzi and Ninni,[5] and De Ritis and Negroni[6] differ somewhat from those in Britain

Whereas British workers have sometimes administered up to 600 mg daily,[1] Italians have not usually given more than 300 mg (in one case Introzzi[5] gave up to 400 mg) Differences in the method of preparation may have something to do with the lower tolerance noted in Italy here the drug is given as a powder in cachets, whereas in Britain it is given in tablets

No depression of hæmopoietic function has been noted, even with protracted treatment[4] With leucopenia due to Hodgkin's disease, the white cell count has gradually returned to normal levels[4][5], while in hyperleukæmic leukæmia, sometimes quite severe, the number of circulating white cells, and more especially of their precursors, has fallen Prolonged treatment has not given rise to severe leucopenia Both in lymphogranuloma and in leukæmia therapy has produced an increase in the circulating red cells, during treatment marrow function seems to revert towards normal

Of 13 cases of Hodgkin's disease, 11 have responded satisfactorily, and in 4 the improvement has been maintained for over eighteen months In chronic myeloid leukæmia the response has been less constant and sustained, though still satisfactory, in each of 8 cases that have been treated pyrexia has decreased and the state of blood and bone marrow has improved 1 case of acute myeloid leukæmia, after some initial improvement, relapsed 2 cases of chronic lymphatic leukæmia responded very satisfactorily both by improvement in the general condition and by lessening of the glandular enlargement

University of Florence PAOLO SPIGLIATI

COMPLICATIONS OF INTRAVENOUS FLUID THERAPY IN CHILDREN

SIR,—A conclusion which I wish that Dr Todd had drawn from his work described in your issue of May 5 is that "cut downs" should only be performed on infants and children when no other means of giving parenteral fluid is possible There has been a tendency in the past to regard "cut downs" and parenteral fluid therapy as synonymous, and this is regrettable since the operation is often unnecessary, and sometimes even disfiguring (are the fashionable ankle bracelets worn to hide the scars of "cut downs" in infancy ?), and, as Dr Todd has shown, it carries a high morbidity

In my opinion the method of choice for giving parenteral fluid (at least in infancy, with which Dr Todd's article mainly deals) is by the subcutaneous route using hyaluronidase Few infants, in my experience, are so severely shocked that they cannot absorb fluid rapidly enough by this route, but, if they are, shock can first be combated by direct intravenous injection using a Kaufmann's syringe, and the restoration of blood-volume can then be completed by subcutaneous fluids

For blood transfusion similarly the method of choice is the use of a Kaufmann's syringe I cannot agree with Dr Todd that this technique is more difficult to learn than that of "cutting down" It is merely a refinement of the technique of venepuncture in adults with which every doctor is familiar, whereas "cutting down" is frequently learnt for the first time in a children's hospital

In practice it is certainly possible to make a "cut down" exceptional without resorting to special units for intravenous therapy Of 290 medical cases admitted under my care in the past year to the Leicester Royal Infirmary, 34 required parenteral fluid therapy, in 23 cases this was given subcutaneously and in 13 intravenously (2 patients were given fluid by both routes) In the intravenous group 19 infusions were given to the 13 cases (these figures do not include patients given blood transfusions as outpatients), in the subcutaneous group repeated or continuous infusions were given In only 3 cases was a "cut down" performed, in 2 this could probably have been avoided by a more expert operator Thus of the 34 cases in hospital who required parenteral fluids, 9% had to have a "cut down" *I feel* sure that others could show a lower figure

Leicester W J MATHESON

VITAMIN-B DEFICIENCIES AFTER GASTRIC OPERATIONS

SIR,—The interesting article by Mr Welbourn and his colleagues in your issue of April 28 emphasises the liability of patients who have had a subtotal gastrectomy to develop symptoms and signs of vitamin B deficiencies, particularly hyporiboflavinosis and mild peripheral neuritis

Similar conditions may occasionally be seen at present in people whose diet is inadequate or whose gastric juice contains no free acid I have met two possible examples in recent weeks

The first, a woman of 28, had complained of numbness and tingling of her hands and legs with slight unsteadiness in walking during the previous nine months She had lost a stone in weight, suffered from flatulence fatigue and depression, and had received psychiatric treatment She said that she had recently had a very sore tongue and sore lips There had been no disturbance of vision or of micturition The only clinical abnormalities were very feeble knee jerks, absent ankle jerks, and absent vibration sense in both legs Test meal showed a histamine fast achlorhydria There was slight anæmia, but no abnormality of sternal bone marrow She had been eating poorly for a considerable time, and it was thought that her condition was the result of a vitamin B deficiency She was given intramuscular vitamin B therapy as an outpatient, and after two weeks she shows marked subjective improvement She says that she can now walk easily again in high heeled shoes and her paræsthesiæ are less The physical signs remain unchanged

[5] Introzzi P Ninni M *Hæmatologica* 1950 34, 925
[6] De Ritis F Negroni G *Min med* 1951 i 75

The second patient, a woman of 58, complained of severe pins and needles and tenderness in the limbs with burning sensations in the feet She could not easily fasten her buttons was unsteady on her feet, and had had several falls She felt very tired her tongue and lips had sometimes been sore, and she had had difficulty in holding her water These symptoms had been noticeable for several months She lived alone on a very poor diet On examination there was slight glossitis, and slight weakness of her hands and lower limbs Incoördination was slight in the hands but marked in the legs Superficial sensibility was impaired in a glove and stocking distribution, and vibration sense was much impaired at the knees and ankles The tendon reflexes were very brisk and were equal, there was bilateral ankle clonus, and both plantar responses were extensor There was some œdema of the ankles Blood count and sternal puncture showed no abnormality, and gastric analysis showed free hydrochloric acid It was thought that this might be a form of nutritional neuropathy with spinal cord involvement She was treated by rest in bed, some walking exercises, and an adequate diet with extra vitamin B (including 'Benerva, Marmite, and 'Multivite by mouth, and 'Cytamen 50' intramuscularly) The power and coördination of her limbs improved so that in a few weeks she became able to walk normally without support and her paræsthesiæ disappeared The objective sensory changes and reflexes remained unaltered

These examples afford no proof of the nature of the complaints, and it is well known that under normal circumstances vitamin B deficiency rarely occurs Possibly, however, a persistently inadequate diet, particularly in the presence of achlorhydria, may lead to a nutritional neuropathy where it would not ordinarily be expected

Parliament

Miners' X-ray Scheme

On the motion for the adjournment in the House of Commons on May 7, Mr E H C LEATHER urged that full advantage should be taken of the work of Dr Charles Fletcher of the Pneumoconiosis Board by instituting a compulsory annual X-ray examination for miners This would reveal the disease in its initial stages when the miner could be given a surface job and a chance of recovery Mr Leather claimed the scheme would cost £135 000

Mr HAROLD NEAL, parliamentary secretary to the Ministry of Fuel and Power, said the question had been remitted to a committee presided over by the deputy chief medical officer of the Ministry of Health, and arrangements for an experimental scheme must await the conclusions of this expert committee, the first meeting of which was to be called shortly

The National Joint Pneumoconiosis Committee had advised that the experimental scheme was more likely to succeed if it was not linked directly with the X ray and dust-environmental surveys at coalmines which were being carried out by, or under the auspices of, the Pneumoconiosis Research Unit of the Medical Research Council Instead, it was aimed to confine the experimental scheme to the routine detection of pneumoconiosis by X rays and to build up a technique of safeguarding men found with the disease by confirming that they worked in, or were given every opportunity to work in approved dust conditions underground Extensive facilities for X-ray examinations were already available Every miner who felt that he might be suffering from the disease could make a claim for benefit, and if he did so he was automatically X-rayed

In the two years ended Dec 31, 1950, about 31,000 X ray films had been used, and 10,000 miners were diagnosed as having pneumoconiosis All of these, whether or not they had decided to remain in the coal-mining industry, were required to report periodically for re examination by a pneumoconiosis medical board The increased confidence of the men in the advice of these boards and in the arranging of test prevention diagnosis was shown by the fact that up to the end of 1950 about 5500 of the 10,000 cases diagnosed had remained at work in the industry

Compensation for Pneumoconiosis

In the House of Commons on May 8 Mr LEATHER asked leave to introduce a Bill to allow compensation to be paid in respect of persons who acquired pneumoconiosis as a result of their employment before July 5, 1918, and who were excluded from the then Workmen s Compensation Acts or regulations made under those Acts because of time limits contained in them Developments in X-ray technique and wider knowledge made it clear that a five-year time limit was unfair The disease was so long in its progression that 15 or 20 years might elapse before symptoms could be diagnosed Leave was given to bring the Bill, which was formally read a first time

National Health Service Bill

On May 9, Lord HADEN-GUEST, Lord-in-Waiting, moved the second reading of the National Health Service Bill The Bill passed through its remaining stages and was read a third time at the same sitting

QUESTION TIME

Membership of Hospital Committees

Lieut Colonel W H BROMLEY DAVENPORT asked the Minister of Labour whether his attention had been called to the withdrawal of the manager of the Sandbach employment exchange from the Arclid Hospital House Committee, and why it was now the general practice of his department not to allow his department s officials to serve on such committees —Mr FRED LEE replied I understand this took place over a year ago No general rule has been laid down about officers of the department serving on a hospital house committee, but it is the general practice of the department not to allow members of the staff to accept office on bodies whose functions include the engagement of labour Lieut Colonel BROMLEY DAVENPORT Is this not gross interference with the liberty of a subject who wants to serve others in his spare time? Why cannot he do it? No further reply was given

Hospitals Expenditure

Lieut Colonel D L LIPTON asked the Minister of Health what action he proposed to take arising from the Auditor-General's report on hospital expenditure —Mr H A MARQUAND replied I think that these matters should best be left to the normal machinery The report will shortly come before the Committee of Public Accounts and in due course be embodied in their report and published evidence, with subsequent action by Treasury minute

Amendment of Dentists Act

In answer to a question, Mr MARQUAND, Minister of Health said that proposals were under consideration for the amendment of the Dentists Act It was not possible to introduce a Bill in the present session but the Government intended to do so at an early opportunity

Red Cross in Korea

In answer to a question Mr JOHN STRACHEY, the Secretary of State for War, stated that the International Red Cross Committee had made repeated attempts to enter North Korea but permission to do so had been refused The Soviet and Chinese governments had previously informed the International Red Cross Committee that they did not feel able to interfere with the sovereign decision of the North Korean government in this respect However the president of the International Red Cross Committee had announced that he was recently permitted to visit Peking, where he saw the prime

AN UNUSUAL ASSOCIATION WITH TOBACCO

SIR,—In the following case smoking seems to have been the cause of an unusual syndrome

In 1926 a woman, aged 40, fainted while playing tennis On questioning she complained of severe pain between the eyes, her pulse was irregular, and she appeared to be so shocked that she was put to bed Within 24 hours the second and third toes of the right foot became painful, swollen, tender, and red, this condition gradually spread until it involved the whole foot and the leg to just below the knee, and the temperature reached 102°F The focal pain in the head gradually passed off after 24 hours, the leg lesion subsided, and after about 10 days the skin of the whole area desquamated, the heart resumed its normal rhythm, and after about a fortnight the patient appeared to have recovered

A similar attack occurred 6 months later, and gradually attacks became more frequent until by 1941 they were taking place at intervals of little more than a month The patient was examined by a number of my colleagues, various diagnoses were made, including angioneurotic œdema, erysipelas, and an unusual manifestation of rheumatism After one attack she was put on salicylates, but these appeared to gravely increase the intensity of the attack X ray examination of the sinuses showed them to be clear, the frontal sinuses were small in development An aural specialist advised washing out the antrums to ascertain if there was any infection, but this was refused

I had noticed through the years that the attacks were related to exacerbations of a chronic bronchitis which the patient had had for some years, and these exacerbations seemed to be definitely related to smoking In 1941 I suggested that the smoking was responsible for the exacerbations of bronchitis and advised that the smoking should be stopped Accordingly it was reduced to two or three cigarettes per day, but this did not diminish the exacerbations, and further attacks affecting the foot and leg occurred with steadily increasing severity In 1943, when it was suggested that a surgical attack should be made on the sinuses, I advised that complete abstinence from smoking should first be tried

This was secured, and since that time no further attack affecting the foot and leg has been experienced, though the patient still has attacks of bronchitis whose severity increases at intervals

Birmingham J F BRAILSFORD

β-NAPHTHYL-DI-2-CHLORETHYLAMINE

SIR,—Reports on this substance in your columns[1,2] prompt me to relate briefly our experience with it in Italy, where the results obtained by Spigliati,[3,4] Introzzi and Ninni,[5] and De Ritis and Negroni [6] differ somewhat from those in Britain

Whereas British workers have sometimes administered up to 600 mg daily,[1] Italians have not usually given more than 300 mg (in one case Introzzi [5] gave up to 400 mg) Differences in the method of preparation may have something to do with the lower tolerance noted in Italy here the drug is given as a powder in cachets, whereas in Britain it is given in tablets

No depression of hæmopoietic function has been noted, even with protracted treatment [4] With leucopenia due to Hodgkin's disease, the white cell count has gradually returned to normal levels [4,5], while in hyperleukæmic leukæmia, sometimes quite severe, the number of circulating white cells, and more especially of their precursors, has fallen Prolonged treatment has not given rise to severe leucopenia Both in lymphogranuloma and in leukæmia therapy has produced an increase in the circulating red cells, during treatment marrow function seems to revert towards normal

Of 13 cases of Hodgkin's disease, 11 have responded satisfactorily, and in 4 the improvement has been maintained for over eighteen months In chronic myeloid leukæmia the response has been less constant and sustained, though still satisfactory, in each of 8 cases that have been treated pyrexia has decreased and the state of blood and bone marrow has improved 1 case of acute myeloid leukæmia, after some initial improvement, relapsed 2 cases of chronic lymphatic leukæmia responded very satisfactorily both by improvement in the general condition and by lessening of the glandular enlargement

COMPLICATIONS OF INTRAVENOUS FLUID THERAPY IN CHILDREN

SIR,—A conclusion which I wish that Dr Todd had drawn from his work described in your issue of May 5 is that "cut downs" should only be performed on infants and children when no other means of giving parenteral fluid is possible There has been a tendency in the past to regard "cut downs" and parenteral fluid therapy as synonymous, and this is regrettable since the operation is often unnecessary, and sometimes even disfiguring (are the fashionable ankle bracelets worn to hide the scars of "cut downs" in infancy?), and, as Dr Todd has shown, it carries a high morbidity

In my opinion the method of choice for giving parenteral fluid (at least in infancy, with which Dr Todd's article mainly deals) is by the subcutaneous route using hyaluronidase Few infants, in my experience, are so severely shocked that they cannot absorb fluid rapidly enough by this route, but, if they are, shock can first be combated by direct intravenous injection using a Kaufmann's syringe, and the restoration of blood-volume can then be completed by subcutaneous fluids

For blood transfusion similarly the method of choice is the use of a Kaufmann's syringe I cannot agree with Dr Todd that this technique is more difficult to learn than that of "cutting down" It is merely a refinement of the technique of venepuncture in adults with which every doctor is familiar, whereas "cutting down" is frequently learnt for the first time in a children's hospital

In practice it is certainly possible to make a "cut down" exceptional without resorting to special units for intravenous therapy Of 290 medical cases admitted under my care in the past year to the Leicester Royal Infirmary, 34 required parenteral fluid therapy, in 23 cases this was given subcutaneously and in 13 intravenously (2 patients were given fluid by both routes) In the intravenous group 19 infusions were given to the 13 cases (these figures do not include patients given blood transfusions as outpatients), in the subcutaneous group repeated or continuous infusions were given In only 3 cases was a "cut down" performed, in 2 this could probably have been avoided by a more expert, operator Thus of the 34 cases in hospital who required parenteral fluids, 9% had to have a "cut down" I feel sure that others could show a lower figure

VITAMIN-B DEFICIENCIES AFTER GASTRIC OPERATIONS

SIR,—The interesting article by Mr Welbourn and his colleagues in your issue of April 28 emphasises the liability of patients who have had a subtotal gastrectomy to develop symptoms and signs of vitamin B deficiencies, particularly hyporiboflavinosis and mild peripheral neuritis

Similar conditions may occasionally be seen at present in people whose diet is inadequate or whose gastric juice contains no free acid I have met two possible examples in recent weeks

The first, a woman of 28, had complained of numbness and tingling of her hands and legs with slight unsteadiness in walking during the previous nine months She had lost

Notes and News

WORLD HEALTH ORGANISATION

THE Fourth World Health Assembly was opened at Geneva on May 7 by Mme Amrit Kaur, India s minister of health and president of last year s assembly At the first session Dr L A Scheele, surgeon general of the United States Public Health Service and leader of the U S delegation, was elected president of the assembly, and Dr D A. Dowling (Australia), Dr A. H. Taba (Iran), and Dr Karl Evang (Norway) were elected vice presidents Colonel M. Jafar (Pakistan) was appointed chairman of the committee on programme Dr G A. Canaperia (Italy) chairman of the committee on administration, finance and legal matters, and Dr M T Morgan (United Kingdom) chairman of the committee on international sanitary regulations Tributes were paid to the late Dr Khalil Bey Egyptian under secretary of State for health, and the late Dr Geraldo de Paula Souza, director of the school of hygiene and public health at the University of São Paulo, Brazil Both were eminent in the field of public health, and Dr de Paula Souza was described as one of the ' founder fathers of W.H O At a ceremony held in the afternoon, Mme Amrit Kaur presented the Léon Bernard Foundation prize, for practical achievements in social medicine to Prof Réne Sand.

In his report for 1950 which was presented to the assembly Dr Brock Chisholm director general of W.H O , said that 100 countries and territories had received help directly from W H.O , while world wide technical services were made available to all nations to fight epidemics, and in other fields An important factor in the progress made by W.H.O in 1950 has been the decentralisation which has taken place, and, with the establishment of regional offices for the Western Pacific and for Africa, the regional network is almost complete A great problem is the shortage of health workers of all kinds said Dr Chisholm, but the organisation has tried to solve it by awarding more study fellowships and by arranging more conferences and seminars A serious development during 1950 was the announcement by 6 more governments of their intention to withdraw from W.H.O and the director general said that if it continued, the negative attitude of the U S S R , Byelorussia China, the Ukraine, Albania, Rumania, Hungary Czechoslovakia Bulgaria and Poland towards W.H.O would have an adverse effect on the organisation

MEDICINE AND THE FESTIVAL

THE Royal Society of Medicine and the British Medical Association have joined forces to play the medical host to Festival visitors at a series of symposia which they are holding at 1, Wimpole Street, London, W 1, from June 4 to July 9 The beam of the debates will range widely, yet focus sharply The first meeting on Monday June 4, over which Sir Henry Dale O.M F.R S will preside, is to be devoted to the Peripheral Nervous System and belongs to the group of systematic discussions, of which other representatives are the Central Nervous System (June 14) under the chairmanship of Dr Russell Brain, F.R.C.P , and the Vascular System (June 8) under Sir John Parkinson. The different specialties claim their due, and Dr A. W S Sichel president elect of the B.M.A., will preside over Ophthalmology (June 11), Sir Gordon Gordon Taylor over Plastic Surgery (June 12) Sir Philip Manson Bahr over Tropical Medicine (June 26) and Sir William Kelsey Fry over Odontology (July 9) Turning from the general to the particular and from the knowledge of the past to the possibilities of the future, the organisers have chosen as further subjects Antibiotics, over which Sir Alexander Fleming F.R.S presides (June 7) and Cortisone' and A.C.T.H. with Prof G R Cameron, F.R.S (June 25) as chairman. The problems of the present are suggested by the meetings on Cardiovascular Disease in an Ageing Population, with Dr J H Sheldon in the chair (June 22) and the fears of the future by Burns, under Dr Leonard Colebrook, F R.S (June 19) The changing fashions of disease are illustrated by the meeting on the Decline of Infant Mortality, which Sir Allen Daley convenes (June 19) and the meeting on the rise in Peptic Ulcer (June 20) at which Sir Henry Cohen, president of the B.M.A. will be in the chair

There are many other interesting and important topics to choose from, and all doctors are welcome to attend the meetings A full programme and application forms for tickets may be had from the joint secretary of symposia, B.M.A House, Tavistock Square W C 1

BRITISH EMPIRE LEPROSY RELIEF ASSOCIATION

ADDRESSING the British Empire Leprosy Relief Association in London last week, the Earl of Halifax, the president spoke of the newer methods of treating leprosy with the sulphone drugs and with thiacetazone The outcome of these advances, he said, had been remarkable, and, while the more conservative still reserved final judgment, all agreed that the change of outlook among the patients was almost miraculous The increasing use of the parent sulphone, diaminodiphenyl sulphone, had so reduced the cost of treatment that in many British territories local funds could at last be found to meet the needs of all cases at present within reach of treatment The association, Lord Halifax said was pleased that its work had earned the unqualified praise of the United Nations Trusteeship Mission which visited West Africa last year, it had been described as an example of human as well as medical achievement worthy of the highest commendation. Another cause for satisfaction was that in 1950 leper children discharged as cured numbered 349—nearly twice as many as in the year before Nevertheless the campaign against leprosy was young and in some areas the need was still very great a recent survey in East Africa showed that the proportion of cases within reach of effective treatment is only 1 in 80 The association s work must be expanded, and fortunately its income was sufficient to enable it to embark on new schemes, though to maintain any new effort the need for funds would be as great or perhaps even greater than ever before The association was ready and anxious to expand, but the difficulty had been the shortage of doctors. The president paid tribute to the work of Dr G A. Ryrie during his four years as medical secretary, and sympathised with him on the decline in health which had compelled him to resign his appointment At the same time he welcomed Dr R G Cochrane who had returned to take up the post of medical secretary after many years in Madras

Dr Cochrane said that progress had been made, not only in the drug treatment of leprosy, but also in understanding of the pathology and in orthopædic methods for preventing and correcting deformities Leprosy was not the hopeless disease it had been, and when doctors realised this then perhaps it would be easier to recruit helpers for the work

Obituary

PERCIVAL MACLEOD YEARSLEY

F R.C.S

Mr Macleod Yearsley, formerly consulting aural surgeon to St James' Hospital, Balham, and to the London County Council, died at Gerrard's Cross on May 4, at the age of 83

A collateral descendant of Dr James Yearsley, the pioneer ear, nose, and throat surgeon in this country, he was educated at Merchant Taylors' School and the Westminster and London Hospitals In 1890 he qualified, and he took his F R C.S three years later

He was appointed to the staff of the old Royal Ear Hospital, then in Soho, of which in due course he became senior surgeon, and he was the first aural surgeon to the London County Council, for whom he carried out important investigations among school children. He also interested himself in the welfare of deaf-mutes

A man of many interests, Macleod Yearsley wrote some delightful fairy tales, studied the story of the Bible, discussed the sanity of Hamlet and doctors in Elizabethan drama, took a scientific interest in the Zoological Society, translated Forel's *Sensations des insectes*, and was an archæologist of repute In his own specialty he wrote a *Textbook on Diseases of the Ear* (1908) and another on *Nursing in Diseases of the Throat, Nose and Ear* Later he became greatly interested in the Zünd-Burguet electrophonoïd treatment of deafness, on which he wrote a monograph in 1933 Energetic, open-minded, and many-faceted, he was looked upon as rather a stormy petrel by his contemporaries, but he mellowed with time, to be regarded with respect and admiration by otologists of today

In his later years Yearsley retired to Gerrard's Cross, where he became ear, nose, and throat surgeon to the local hospital He married Florence Louise, daughter of the late Dr C M Cooper, and she survives him with a son.

GERALDO HORACIO DE PAULA SOUZA

M D

International health has suffered a loss in the death after a short illness of Prof G H de Paula Souza, director and professor of public health at the University of São Paulo, Brazil Beginning his career in international health as a medical officer of the Health Organisation of the League of Nations, he served for a time with UNRRA during the war and represented Brazil at the Technical Preparatory Commission in Paris and the World Health Conference in New York in 1946, and on the Executive Board and at the World Health Assemblies of W H O He will chiefly be remembered for his successful insistence, with the representative of China, that the San Francisco conference should include health in the functions and structure of the United Nations, as well as for his concern for the wider issues of public health, his stand against parochialism, and his never-failing personal courtesy and kindness

PHYSICAL EXERCISE *

ITS CLINICAL ASSOCIATIONS

SIR ADOLPHE ABRAHAMS
O B E , M.A., M D Camb , F.R C P
CONSULTING PHYSICIAN TO WESTMINSTER HOSPITAL

PHYSICAL exercise may be defined as exertion of muscles, limbs, and bodily processes regarded with reference to its effect on the subject But it is customary to limit such exertion to that which is undertaken with a view to the maintenance or improvement of health Indeed so established and intimate is this special association, that we are accustomed to append qualifying adjectives such as open air, carriage , horse , walking-, and others, according to particular requirements of exercise as a therapeutic prescription

In what respects does the subject interest or concern the clinician ?

In the first place he will naturally be credited with knowledge of the anatomical and physiological principles of exercise in general, and expected to explain and advise the type, the limitation of its extent, and the individual requirements according to age, sex, social position, and opportunities These are details which regard exercise as commensurate with other hygienic principles upon which advice is habitually asked , such as food, clothing, alcohol, tobacco

What is popularly termed violent exercise—that is, exertion to the limit of capacity or endurance—occupies an important place and fulfils an important function in civilised countries The clinician will be expected to pronounce upon the possible danger to the admittedly healthy, especially to the cardiovascular system when exposed to extreme stress or so called strain He will be asked to decide the significance of certain lesions and conditions—whether they may be completely disregarded of should be accepted as interdictory of unlimited effort He will, rightly or wrongly, be assumed to be an authority on “ training ”—that is, the preparation for athletics—and in consequence consulted on such matters as the selection of appropriate foods or so called stimulants The familiar associations of stitch, cramp, stiffness, and staleness will also be regarded as within his province

There are special gynæcological considerations that call for his attention, such as the place of exercise during pregnancy and after delivery, more especially on account of the increasing proclivity of girls and young women to participate in activities hitherto regarded as the male prerogative

The injuries that occur in sports and competitions—such as sprains, bruises, fractures, dislocations, concussion, indeed traumata of all kinds—require the applications of fundamental surgical principles with certain technical requirements, as when an athlete requests exceptionally rapid or immediate results These need not be comprised within my present thesis, a conclusion that applies to remedial exercises in general. Yet I may diverge in parenthesis to recall the application of graduated exercises in the treatment of some forms of *cardiac disease* and of *pulmonary tuberculosis* In *diabetes*, exercise is accorded a prominent therapeutic place along with diet and insulin Prolonged inactivity lowers sugar tolerance in the non diabetic confined to bed (Blotner 1945), for with lessened demand for the rapid storage and utilisation of sugar the pancreas is rested, and diabetic reactions may occur even with a normal fasting blood sugar At least one diabetic subject has despite his disability reached top ranking in lawn tennis, although reduction of his insulin dosage demanded by severe competitive exercise calls for some circumspection in the avoidance of hypoglycæmia Even sufferers from *myasthenia gravis* have under the influence of neostigmine been capable of strenuous exercise, although the wisdom of such indulgence may well be questioned

INSTINCT AND INSTRUCTION

In a state of Nature the demand for physical exercise is satisfied as instinctively as the demands imposed by hunger, thirst, and cold the mere circumstances of existence ensure a sufficiency But in civilised life the relative increase in sedentary work and the shift to mental and intellectual forms of human endeavour are so predominant that, with the exception of certain natural occupations such as farming, hunting, and lumbering, physical exertion is reduced to negligible proportions And even in these, the introduction of machinery encroaches continuously upon the physical application Fifty years ago, the urban population of the United States was estimated at 2% it is now 60% Comparable changes have occurred in this country The necessity or craze for speed together with the convenience of improved and increasingly rapid means of locomotion make the city dweller less and less inclined to utilise his own natural means of progression

There are other elements in urban life that contribute to the necessity of regarding exercise as essential to health The ever increasing protective influence of clothing, of wind sheltered dwellings, and of artificial heating withdraws people more and more from a struggle with the rigours of Nature City dwellers become concentrated in an atmosphere charged with gases of imperfect combustion, and through a canopy of soot and dust deprived of direct sunlight Amusements and recreations inevitably mean congestion in crowded public places, with exaggeration of these disadvantages and the addition of infection Open air exercise must then be designed for its antidotal effect In many instances an instinctive urge ensures a sufficiency, in others it will be more or less deliberately undertaken as a measure of hygiene If exercise is instinctive and to a considerable extent a vital necessity, why should advice be needed ? Because it differs from such essentials as food and clothing, and similar familiar requirements, in which, when error in their application is committed, it is either from some inevitable cause of hindrance or from wilful infringement of laws ignorance of which cannot be pleaded In the case of exercise, although the evils which arise from abuse or misapplication are really as direct as those that follow the non observance or misapplication of any other agent of health, they follow less suddenly on committal of the fault Reminders of neglect speak not with the imperative voice of hunger or thirst or cold or oppressive heat or fatigue

Were the physical component the only one to be considered it would suffice to proceed on simple dynamometric lines But, fortunately, the psychical side, the factor of recreation, the satisfaction of the play instinct, perpetually operate to secure Nature’s requirement indirectly but more advantageously When, for example, walking alone is avoided as too insipid, and the claim to its traditional constitutional value is disregarded, all kinds of accompaniments may be introduced to increase attractiveness As is well known, a man who would not willingly walk a dozen yards when a hospitable vehicle presents itself, can easily be persuaded to follow a little white ball over several miles of varying country Shooting, fishing, croquet, bowls, butterfly hunting, collecting fossils, and similar outdoor pursuits, undertaken according to taste and fancy, ensure a sufficiency of fresh air and exercise for the less vigorous

In fact, when called upon to discuss the necessity or at least the advantage of exercise with a patient who regards the advice in the light of a conventional prescription, the practitioner will pay particular attention

---

* The first Lumleian lecture for 1951 delivered before the Royal College of Physicians on April 10

Royal College of Obstetricians and Gynæcologists

At a recent examination for the diploma in obstetrics, the following were successful

E A Agius A S Arnoll, Janet M Bell D G B Bennett E I Boxer H S Brown, J A C Brown C B Burdett Smith R K Burt J D Chalmers, R A Chesterfield Joanne M Clements, J F Connolly J S Cox T I Crichton J M A Critchley Margaret E Davies J A Dow A J Dinn H G Dixon D C Dymond, Emrys Evans Harriet Faris Margaret M Farrell Ethel A Fisher, Hanora H Forde J M Frew, D C H Garrod, H S Gavouin Nagendra Nath Ghosh H J Giwelb, N G O Courlay Michael Grant, Kenneth Greig Peter Griffiths Harry Haigh J S Happell W T Harrett J W S Harris Kathleen J Harrison Patricia E Hartley M M Herbert G J S Herdman Ruth N E Hinckley J G Inglis, W G Irwin Bernard Isaacs W C Jamieson Dorothy M Jennings A T Johnson A W Johnson Krystyna Maria Kawa H M Kent Gordon Kettlewell H M Kirkpatrick, Po Chuen Lai Catherine M Lamplugh, D C Langwell Joyce H Lazarus J J Lee William Lees, T P Linehan C D Linton H A R Loxdale H S McCallum Austin McCawley D P McDermott James McDowall Susanne M Macgregor W J M Mackenzie F J McKenna, L P Mackie Cynthia J McPherson, L J Mann J G Mathie Brian Measday, Margaret L Meikle A L Mintz Rhona E Morgan F J Mouser Jessie M B Muirhead Anne M M Oriel Eliasz Perelman Evelyn Peters Violet M J Procter Margaret D F Quinet A J H Reford A M Reid D H Richards J H Ridgwick Freda M Roberts D J Rodger I P Ross Mark Sackwood I N Samuel Joycelyn H W Sandison Muriel J Scudamore Henryk Seid Parmeshwar Narain Sinha June M Smith P M Smith Isobel M W Stark, R G O Taylor O H Taylor Eirian Thomas Somasundrum Thurairetnam W L Timmins F L Trott A C Turnbull Ethel M Wallis Alexandra C Watson Pamela L C Watson Margaret L Watt, Grace A M Webster H M White H W Wilson M B Wingate P A T Wood Frances M E Wylde

Royal Faculty of Physicians and Surgeons of Glasgow

At a meeting held on Monday, May 7, with Mr Walter W Galbraith, the president, in the chair, the following were admitted fellows of faculty

A C McDougall Mallaraj Basavaraj Urs *qua* physician, B McK Dick *qua* surgeon

Faculty of Ophthalmologists

The following have been elected officers for 1951–52 president, Mr O M Duthie, vice presidents, Mr R C Davenport and Mr A B Nutt, treasurer, Mr E G Mackie, secretary, Mr J H Doggart

West Midlands Physicians Association

The second meeting of this association will be held at the North Staffordshire Royal Infirmary, Stoke on Trent, on Saturday May 26, at 11 A M

Conference on Maternity and Child Welfare

The National Association for Maternity and Child Welfare are holding their annual conference at Church House, Westminster, London, S W 1, on June 27, 28, and 29 The conference will be opened by Princess Elizabeth at 10 15 A M on June 27, and the speakers will include Dr E Ashworth Underwood, Dr R C Lightwood, Dr Mildred Creak, Dr J L Burn, and Dr Alex Russell Further particulars may be had from the secretary of the association, 5, Tavistock Place, W C 1

Harveian Society of London

At this society s Buckston Browne dinner on May 10, the toast of The Society was proposed by Mr L S Amery, who spoke with humour of the difference between politics and medicine Politicians, he declared submitted to none of the exacting tests undergone by those who attended the temple of Aesculapius Our only qualification is our own good opinion of ourselves as members of the body politic We politicians shamelessly advertise our nostrums Of Harvey he spoke with admiration as the first person to make our blood circulate ' Mr Amery remarked that in a life time the pulse beat 2500 million times To what purpose ? he asked, and went on to provide some thought provoking answers In his reply Mr W L Tucker the president, suggested that in the National Health Service professional harmony was tending to become disrupted, partly owing to the wages policy This disruptive trend should be arrested, and the Harveian Society could make its own contribution by bringing together all manner of doctors Sir Alexander Maxwell and Mr Basil Cameron replied for The Guests to a toast proposed by Dr Brian Warren Sir Alexander Maxwell urged the need for close understanding between Britain and the U S A, for without this the outcome for the world might be catastrophic He implied that one factor dividing the two nations was their common language which obscured the need for effort " We must get to know our American friends '

Lebanon Hospital for Mental and Nervous Disorders

The 52nd annual meeting of this hospital will be held at the Cora Hotel Upper Woburn Place, London, W C 1, on Monday, May 21, at 3 P M, when the Earl of Feversham, the president, will take the chair The speakers will include Dr J C Sawle Thomas and Dame Katherine Watt, R R C, both of whom have visited the hospital during the past year

National Council for the Unmarried Mother and Her Child

A meeting of this council will be held at the County Hall, Westminster Bridge, S E 1, on Wednesday, May 23, at 2 30 P M Miss Robina Addis, Miss Eve Kennedy, and Prof R M Titmuss will open a discussion on Unmarried Parents—the Background for the Social Worker

Students' Clinical " At Home "

On April 20 the Junior Common Room Society of the Middlesex Hospital was at home to 6 students from each of the other London teaching hospitals, and the programme consisted of both clinical and social functions The visitors were directed, as far as possible in accordance with their own choice, to one of ten teaching rounds or to some urological operations One round was given by Sir Gordon Gordon Taylor, and the others by present members of the hospital staff Altogether over 200 students attended these various rounds After tea Dr C E Lakin gave a lecture entitled Nec Silet Mors A sherry party for the visitors and members of the staff was held in the evening, and was followed by a dinner

Chelsea Clinical Society

Proposing the toast of the Chelsea Clinical Society at the annual dinner on May 8, General Sir Ronald Adam, chairman of the British Council, spoke appreciatively of the work of those members of the profession with whom he had been associated in the Army He went on to speak of the council s work in bringing the successes of British medicine to the notice of other countries The retiring president, Mr Geoffrey Parker, replied to the toast The toast of The Guests was proposed by Dr N L M Macmanus, and Lord Horder and Prof E C Dodds, F R S, replied The president then made a presentation to the retiring secretary, Mr H Paxton Baylis, and Dr K E Eckenstein, the treasurer, spoke of Mr Baylis s long and loyal service to the society After the presentation, Dr J H Dunn was inducted as president for the coming year

WALLACE —On April 26 George Smith Wallace O B E M B Glasg D P H colonel R A M C retd aged 72

YEARSLEY —On May 4 at Gerrard s Cross Bucks Percival Macleod Yearsley F R C S aged 83 means to that end, including the obvious one of muscular exertion Physiologists have shown what preposterous misconceptions were generally held about this alleged aid to reduction

Since in the performance of any exercise the oxygen consumption can be accurately measured, and since a litre of oxygen is the equivalent of 5 calories, the exertion corresponding to the oxidation of a standard pound of body-weight in the form of fat (i e, 4230 calories) is merely an affair of simple calculation To those who have hitherto thought only vaguely of the potentially reducing power of exercise the revelations are startling Thus, at the ordinary reasonable walking pace of $3^1/_2$ miles an hour, which requires an oxygen consumption of 0 75 litre per minute, one mile is the equivalent of 65 calories, so combustion of the pound of fat would necessitate a constitutional of some $66^1/_3$ miles spread over about 19 hours

Terpsichore is from this angle a not very efficient adjuvant, for 16 hours of the foxtrot would be necessary for the same reduction

Of course the oxygen consumption is much greater with strenuous exertion A sprinter at full speed is expending energy that demands approximately 6 litres of oxygen in 10 seconds Even so, were it humanly possible to continue at this extreme speed, $7^1/_3$ miles would have to be covered to draw on the pound of fat And turning to a practicable physical achievement, running at the rate of 10 miles an hour, which is the pace of a good marathon runner, no less than 43 miles would be necessary

Almost certainly there is some other factor that is more elusive Is it not likely that regular exercise sets the basal metabolic rate at a higher level operating throughout the twenty four hours? Superficially it would seem that appropriate estimation ought to prove or disprove such an explanation, but in actual practice it has not been found easy to obtain convincing evidence

It is generally agreed that getting fat is not due to anything so simple as want of energy expenditure It is a habit of the body, and exercise, especially if undertaken regularly, in some way helps to acclimatise the body to it, as in the case of almost everything to which the human body may be subjected Yet even the greatest enthusiast is compelled to admit the comparatively limited application of exercise, more especially as the subjects most desirous of reduction are obviously incapable of exertion of great severity or prolonged duration

Loss of weight must of course be distinguished from genuine loss of fat In strenuous exercise there may be considerable loss of water from the body from perspiration and to a lesser degree, through respiration I found in myself a loss of three pounds in weight in half an hour's climbing in Switzerland A loss of from four to ten pounds has been noted in a marathon runner This loss is restored within the ensuing three days, sometimes within twenty four hours

DIET AND FITNESS

The clinician will be expected to advise upon the nature and quantity of food likely to contribute to physical fitness and athletic prowess His task will be neither easy nor agreeable in attempting to reconcile fetishism with sober physiology He will strip the mystery from much that has no greater foundation than tradition, and the iconoclast is never popular

Diet in athletic training has always received more than its proper share of attention It has been credited with attributes and possibilities always exaggerated and largely imaginary Although most of the outrageously unphysiological precepts of old time training have largely disappeared, a few survive as if something must be retained amid the shifting quicksands To this day belief persists that energy, stamina, strength, and endurance are directly obtainable from what one eats rather than from what one does, and advice will be sought upon articles of food that can increase respiratory power or cardiac efficiency Although his opinion will be greeted with some degree of incredulity, the practitioner will be of service in pointing out that the energy expended is comparatively so little that there is no justification deliberately to increase the usual food intake, especially of animal protein, a practice which will often lead to indigestion and other disturbances Alternatively, the reputation of articles of diet said to be bad for training has in the majority of cases no foundation of any kind There are psychological reasons for the admission of some alimentary generosity in order to avoid the bugbear of staleness, but these are outside laboratory calculations

The practitioner will have more difficulty in discrediting the alleged value of concentrated comestibles or complex vitamin preparations

During World War II, some anxiety being felt that stereotyped rationing might lead to undernutrition and malnutrition, a number of investigations were undertaken to estimate the effect of administering vitamins One series of experiments showed considerable improvement in performance of various physical tests Another series, however, showed convincingly that there was no evidence whatever of any such benefit, and the most reliable conclusion to be drawn is that given an adequate diet, supplementation with vitamins serves no useful purpose (Keys and Henschel 1942) Nor did parenteral injections lead to any increase in muscular efficiency (Foltz et al 1942)

These laboratory investigations confirm the observations of those who have been in intimate contact with great athletes. Machines differ in their fuel requirements and the human machine is no exception Dietetic peculiarities are simply those of individual taste, the dictates of natural inclination

THE HEART IN EXERCISE

Since, rightly or wrongly, solicitude is applied to the work undertaken by the heart in extreme exertion and the possibility of strain and permanent injury, a few details relating to the circulation will not be out of place

In an average healthy subject at rest, each ventricular contraction at the rate of 72 per minute, expels 100 ml. ($3^1/_2$ ounces) or about 7 litres ($1^1/_2$ gallons) of blood per minute During extreme exertion the ventricular output may be more than doubled and the cardiac frequency rise to 160 and on occasion higher The minute volume thus increases to 37 litres (8 gallons) Expressed in more homely statistics, this is the equivalent of a bath room tap turned full on Such spectacular figures encourage the presumption of danger and damage, apart from the symptoms of discomfort that may arise and the appearance of distress so alarming to an onlooker The traditional expectation of injury is that of a dilated heart, but it would appear that some confusion of thought is related to the terminology

When such discrepant statements are made as that the heart enlarges in exercise and that the heart after exercise is smaller, it is clear that technique in estimation and measurement must in one of these circumstances be incorrect or that there is some fundamental misconception

It is universally accepted that at the beginning of exercise, when the coronary blood supply has not reached its maximum, the heart dilates in order to increase the efficient contraction of its individual fibres Dilatation then is an essential part of the mechanism by which it can increase or maintain its output in response to a greater venous inflow or a higher arterial pressure. It is a perfectly normal process, and the extent to which it can take place is limited by the pericardium Even so, a considerable addition to its content of blood at the to the psychological side, remembering that even if accepted as medicine it is not necessary that medicine should be unpalatable There cannot be one best form of exercise for all persons One man's pleasure is another man's madness The ascent of high mountains, for example, is a penal discipline one of the fiercest torments of the Greek Hell is regarded as one of the sublimest pleasures of an English holiday, a commentary on the saying that some of us take our pleasures very sadly The exercise that gives unqualified enjoyment to one may inspire boredom in another and be interpreted as a form of torture by a third Formally to advise or order exercise without regard to the individual's tastes, quite apart, of course, from his physical capacity, is equivalent to the employment of a universal prescription or a dietetic régime on Procrustean lines

OUTLETS FOR AGGRESSION

The more strenuous forms of exercise which include the element of competition to a greater or less degree, represent the primitive instinct of strife, which, however stifled and suppressed by civilisation, nevertheless survives, and survives to some purpose It seems that human beings were not born to be the gentle kind creatures that religion would desire Judging by the past, and unhappily, too, the present, the lion who may some day achieve the prediction of the prophet and lie down with the lamb will be a very senile lion on the point of death

Modern games and athletics are basically conventionalised outlets which help the civilised citizen to express his emotions vicariously and to control his radical aggression, the aggression for which the organism was constructed and which all animals to survive must practise Aggression is thus expended in a regulated fashion without resorting to primitive ways As William James says even if the day ever dawns in which muscular vigour will not be needed for fighting the old heavy battles against Nature, it will still always be needed to furnish a background of sanity, serenity, and cheerfulness, to give moral elasticity to our disposition, to round off the wiry edge of our fretfulness, and make us good humoured and easy of approach

BENEFITS OF ACTIVITY

The picture of the unnatural conditions of urban life represents the ill effects of taking no exercise Considered from the positive aspect, activity will be directly or reflexly related to all the functions of the body, chiefly as a result of an increased provision of oxygen

First, one naturally considers the circulation, the tide on which is brought up all fresh material for incorporation in the tissues and on which is borne away all that is effete The call for increased cardiac frequency on effort results in decreased frequency during rest, with improved output and lower blood pressure A reserve is created which may be utilised in the maintenance of life under adverse conditions In general, the body is educated to deal with emergencies

Ventilation of the lungs is increased, especially at the apices The mechanism of temperature control is tuned up , the nervous system is trained in coordination A higher level of motor integration automatically ensues Muscular movements are conducted with greater economy, whilst latent fibres are employed and more oxidising and metabolic enzymes are developed The integrative effect is not confined to the voluntary muscular sphere it extends deeply into the autonomic field A sense of strength and well being engenders, colours, and reacts upon the outlook and actions as a whole

The bone marrow is stimulated by the oxygen want which is a temporary consequence of vigorous activity There is a reflex enlargement of the suprarenals Bodily movements lead to massage and increased motility of the alimentary canal with improved coordinated control of the mechanical factors of digestion

The relationship of exercise to the gastro intestinal functions demands a more critical examination than traditional everyday experience can supply The so called constitutional walk to create an appetite is not simply the exponent of physical exertion as is popularly supposed—a misconception which, as I shall show later, is particularly related to obesity Appetite has a far greater psychological background in the stimulating effect of moving air upon the exposed parts of the body and the enjoyment which depends upon a number of influences according to tastes and temperament

Campbell and his colleagues (1928) found by the employment of test meals, that walking at the easy pace of $3^1/_2$ miles an hour increased the rate of emptying of the stomach, and that simultaneous agreeable conversation was more effective than exercise alone In exercise of greater severity, both the gastric secretion and the rate of emptying were decreased Presumably cutaneous vasodilatation with relative anæmia of the stomach is the main responsible mechanism

They found considerable individual differences, corresponding no doubt to natural ability for exertion and the customary degree of participation They found that on the whole the rate of digestion was increased in any exercise that did not produce discomfort—an observation supporting the common experience that a child often takes vigorous exercise after a meal, a practice of which an adult is quite incapable, an example of the value of instinct as a guide to what is physiologically sound

By enthusiasts too much may easily be claimed Contrary to popular belief, there is no evidence to support the view that a high standard of physical fitness is associated with, or conducive to, the attainment of special resistance to infectious diseases Muscular efficiency and athleticism are special features They are not incompatible with health and resistance to illness but they are not necessary accompaniments Physical training as such improves the ability of the body to deal with situations with which exercise confronts it, an adaptation, an automatic utility irrespective of whether the organism is healthy or not Properly conducted recreational activities impart a psychological release and so enhance equanimity but are incapable of generally improving a man's health or resistance to illness A great number of sedentary workers take little or no deliberate exercise but seem to be quite as normal in respect to infection as their physically more strenuous fellows

The remarkable improvement in the physique of the subnormal recruit to the Fighting Services may be unduly attributed to the physical training This, of course, plays its part, but one has to remember the many concomitant advantages—abundant wholesome food, the discipline of regular habits and other hygienic circumstances, freedom from the pecuniary and social anxieties of a precarious life with intermittent unemployment, and so on and so on

EXERCISE AND OBESITY

Although the association of physical activity with obesity must always have been recognised, until comparatively recently little attention was paid to this or for that matter any other method of reduction The tendency to put on weight, the middle aged spread as it was called, or the rather euphemistic and chivalrous expression, the well covered woman, was accepted as inevitable , and so far as exercise was related, most people were not at all clear in the differentiation of cause and effect

At the end of World War I, when for some reason or other the natural feminine conformation became unfashionable, the craze for slimming (still persisting) encouraged and demanded investigation of all possible women of a particular physique and temperament are likely to be interested in sport, in which they see an opportunity to compensate for what is felt to be the inferiority of being feminine

Even in men, the anxiety and tension, the disturbing influence of the limelight of adulation and hero-worship, may adversely affect the nervous system It might be contended that such influences would be still more deleterious to young women—a presumption which is, however, stoutly denied by those who claim for women a capacity for adjustment and stability superior to that of men

In the year preceding World War II, a committee was appointed to investigate the details upon which obstetricians and gynæcologists have expressed widely differing opinions We interviewed many women prominent in the world of sport as active participants or as officials or entrusted with the charge of girl athletes. In addition, a questionary was circulated among a considerable number who in their youth had indulged in athletics and other competitive exercise and had subsequently borne children, with inquiries as to their pregnancies, deliveries, and general health. Many stated that dysmenorrhœa, so far from being aggravated since engaging in such exercise, was markedly improved. No indication was forthcoming of relative sterility, of disturbances during pregnancy, or of difficulty in delivery The criticism is obvious that we were dealing with enthusiasts but what other material was available?

The outbreak of war terminated the inquiry, which would have been extended particularly in the direction of psychology It must be admitted that the unæsthetic accompaniments that on occasion cannot be overlooked may inject a degree of prejudice that handicaps judgment on the physical side This is an unavoidable weakness in human nature most people see what they wish or expect to see

SEQUELÆ OF RADICAL GASTRIC RESECTIONS

CLINICAL AND METABOLIC FINDINGS IN 35 CASES

R H F BRAIN
M.B Birm. F.R.C.S

CONSULTANT THORACIC SURGEON MID WORCESTERSHIRE GROUP OF HOSPITALS LATELY SENIOR SURGICAL REGISTRAR THORACIC UNIT QUEEN ELIZABETH HOSPITAL, BIRMINGHAM

With an Introduction by

F A R STAMMERS
C B.E , Ch.M. Birm., F.R C S

PROFESSOR OF SURGERY, UNIVERSITY OF BIRMINGHAM

SURGICAL technique, aided by its modern adjuncts and ancillary services, has become so safe that hardly any operation is inherently impossible Hence the fashion is for more and more radical procedures, but the time has now come for surgeons to ask themselves whether, from the patient's point of view, such and such an eradication is psychologically and physiologically justifiable. Furthermore, every effort should be made to explain, with the aim of preventing or at least mitigating, the secondary discomforts of radical surgery that sometimes lead patients to question the value of their operations I therefore suggested that Mr Brain should investigate the sequelæ of total and near total gastrectomies, particularly the failure of these patients to gain weight and strength, and their liability to diarrhœa, anæmia and deficiencies of vitamin B complex

---

In the past $3\frac{1}{2}$ years some 40 total or near-total gastrectomies were performed at the Queen Elizabeth Hospital Birmingham, and 35 of the patients had some form of special investigation We paid particular attention to the postoperative period, and made detailed metabolic studies of some of the cases

TABLE I—CLINICAL FINDINGS IN FOLLOW UP OF 33 GASTRECTOMY PATIENTS

Clinical feature		Total gastrectomy		Near total gastrectomy	
		For cancer (13 cases)	For other conditions (4 cases)	For cancer (10 cases)	For other conditions (6 cases)
Appetite		Good	Good	Good	Good
Capacity for food					
Limited		12	4	8	4
Increased		1		2	2
Dumping syndrome					
Mild		11	2	5	2
Severe		1	1	3	1
Dysphagia due to					
Stomatitis Œsophagitis Spasm	Regurgitation of alkaline juices	3	2	3	3
	Vitamin B deficiencies	6	1	3	
Organic obstruction		1			
Diarrhœa		12	4	9	4
Constipation		1		1	
Weight					
No gain		12	4	8	4
Rise to normal		1		2	2

Most of the patients were operated on for cancer of the stomach, often of the cardiac end, and it must be emphasised that our inquiry was concerned only with the most radical resections Nevertheless, the cases still varied both in the nature of the lesions present and in the severity of their operations, the patients were therefore divided into four parallel series, as follow

Series 1 —Total gastrectomy for cancer

Series 2 —Total gastrectomy for non malignant conditions

Series 3 —Near total[*] gastrectomy for cancer

Series 4 —Near total gastrectomy for non malignant conditions

On the whole, the postoperative findings were much the same in each series

CLINICAL PICTURE

Both surgeons and physicians have lately become increasingly aware that patients who have a gastric resection, particularly a radical one, are by no means normal afterwards (see leading article in *The Lancet*, 1950, ii, 373) Even after a "routine" partial gastrectomy for simple ulcer, loss of weight and excessive excretion of fat in the stools are often noted (e.g , by Wollaeger et al. 1946) The follow-up findings in a large series of cases of duodenal ulcer treated at the Queen Elizabeth Hospital by vagotomy alone,[†] when compared with a similar series treated by partial gastrectomy, revealed striking differences in the general nutrition of the two groups In the vagotomy series, the patients who became symptom free often gained up to 2 stone in weight after the operation, whereas the gastrectomy patients, though they seemed otherwise well, gained only a few pounds at best Where total gastrectomy was done, even for non malignant conditions—e g , a case of gastric polyposis—the patients looked almost like the wasted inmates of Belsen Camp

It seems that a radical gastric resection initiates a state of "katabolism" leading ultimately to stabilisation of the patient's metabolism at a body-weight much below end of diastole will produce a comparatively slight increase in the diameter of the heart. At the termination of exercise clinical estimation of the heart size is prone to error: widespread vigorous pulsation precludes accurate localisation of the apex beat. Radiography, however, points to a reduction in size, as would on mechanical grounds be expected.

---

[*] The terms near total and "subtotal are both used in this paper to describe gastrectomies closely approaching total

[†] The treatment of duodenal ulcer by vagotomy alone was subsequently abandoned at this hospital.

But, protest the alarmists, it is an ultimate permanent enlargement that is to be feared. And since cardiac hypertrophy is so intimately identified with a pathological condition of the vascular system, or of some other system with cardiovascular repercussions, an indictment of violent exercise is comprehensible. The pertinent features to be examined would appear to be the following:

1. Is there evidence of cardiac hypertrophy in those accustomed to violent exercise?
2. If such hypertrophy occurs, is it pathological or is it a hypertrophy homologous with that of the voluntary muscles?
3. When cardiac hypertrophy is apparently related to athleticism, is it necessarily the result of exercise? May it not be evidence of a naturally large heart in a human being constitutionally fitted for protracted exertion?

When with hypertrophy the muscular fibres enlarge without increase in the number of capillaries, each capillary has to supply an increased mass of muscle. Efficiency is in consequence impaired because the exchange of oxygen and metabolites is impeded. That is the condition of a heart enlarged through some pathological state. On the other hand, hypertrophy in the sense of increased capillarisation is not necessarily enlargement in the clinical sense.

Tung (1934) found that 45% of rickshaw pullers had enlarged hearts. But pathological influences can by no means be excluded. The life of the rickshaw pullers is extremely precarious. Owing to their small earnings, they cannot feed, clothe, and house themselves properly, and they are exposed for long hours to all the inclement weather the climate imposes. Moreover the physical output is comparatively small.

Radiological investigation of athletes who have exerted themselves over long periods provides no evidence of recognisable enlargement. Lee (1915) satisfied himself that there was no difference between the size of the heart in men who had been rowing for two years and in those who had been rowing for ten years, and very little if any difference from those in a younger group who had not rowed at all.

Turning to the constitutional factor. May not man share the privilege of selection, as in the Animal Kingdom generally? The wild hare has, weight for weight, three times the heart muscle of the wild rabbit. The greyhound by virtue of generations of strenuous exercise, or as a result of selection, is endowed with a proportionately large heart at birth—a heart which responds, to schooling and training, by hypertrophy. Thoroughbred colts have comparatively larger hearts than the ordinary run of horses (Herrman 1925–26). How far this is evidence of the inheritance of acquired characteristics or the result of selection through generations of racing stock is a matter for speculation. In the case of man, any such investigation is in the vast majority of cases limited to X ray estimation of the volume of the heart, calculating its weight and relating this to body weight. Using this method, Bramwell and Ellis (1931), working with competitors at the Olympic Games at Amsterdam in 1928, found that the marathon runners had relatively large hearts, with a ratio to body weight of 1/46.4 as compared with 1/63.8 in shorter distance runners. Opportunities for the more accurate direct estimation of the heart weight are naturally very rare. The isolated example I am able to advance is of exceptional interest (Abrahams 1946).

A man of 78 died suddenly during a course of deep X ray therapy for malignant disease of the thyroid. As a necropsy was permitted, I requested particular attention to the heart and blood vessels, for his career as an athlete in his youth had been of almost legendary order.

He was, in the opinion of authorities, the greatest long distance cyclist of all time. At the age of 18 he broke records for the bicycle and tricycle rides from Land's End to John O'Groats, for which achievement he had an insatiable partiality. Contemporary members of our profession warned him that every such performance reduced his life expectation by 10 years; but he accomplished it on 24 occasions. After terminating his career as a long distance cyclist he continued as an outstanding performer at cricket, hockey, swimming, and lawn tennis for the remainder of his life, during which his health remained excellent.

At the necropsy the cause of death was found to be an embolus in the left pulmonary artery. The heart was conspicuously large, weighing 18 ounces (509.4 g). The muscle was firm and without fatty changes or infarctions. The coronary vessels were entirely free from atheroma. The aorta was in a remarkable state of health. The valves were normal. All other viscera were healthy.

It is probable that similar examples of natural hypertrophy would be discovered if necropsies on famous athletes were performed, and if, in the case of those who died at an advanced age, care was taken to assess the usual degenerative changes.

In this connection a reference is desirable to the condition known as "idiopathic" hypertrophy of the heart—a term that suggests, superficially at any rate, the possibility of confusion with the constitutional hypertrophy of the superathlete, but in fact a grave pathological state. Termed "idiopathic" because of an unknown ætiology, it is usually fatal in early childhood, but three examples have been described in which the patients survived to the ages of 18, 29, and 31 (Levy and Rousselot 1933). There was in these young adults no history of violent exercise or of excessive fluid intake; the hearts post mortem weighed 740 g (26 oz), 750 g (26½ oz), and 640 g (22½ oz) respectively. Areas of degeneration and necrosis were visible in the myocardium. Microscopically, the heart muscle cells showed hydropic degeneration with vacuolisation of the sarcoplasm similar to the condition of the myocardium in fatal cases of diphtheria.

Whittle (1929) described the case of a student aged 20 who fell off his bicycle and died within a few minutes. Post mortem his heart was found to weigh 800 g (28 oz). Although the only exercise indulged in had been that of ordinary cycling, Whittle considered the muscular exertion to have produced this remarkable cardiac hypertrophy, a conclusion surely quite unacceptable. This patient must have belonged to the group alluded to by Levy and Rousselot when describing the three cases under their care.

EXERCISE FOR WOMEN

The physiological and recreative advantages of exercise apply to women equally with men; but when the more strenuous forms and especially those involving competition are in question, some circumspection is desirable. The modern tendency towards participation in track athletics calls for inquiry whether woman's special function in Nature may not be seriously prejudiced. For guidance, we look to our gynæcologist colleagues and we find conflicting opinions. Some regard athletics as harmful by increasing the incidence of disturbances of genital functions, especially menstrual disorders and sterility. Others not merely deny these ill effects but believe the very opposite. Some obstetricians are convinced that in women who have indulged in a great deal of exercise difficulties occur at parturition through muscular rigidity. Others of equal experience have failed to identify any such influence.

There is the psychological factor. Sport, especially of a highly competitive character, is held to bring about changes of a masculinising nature, with production of the virago type. An alternative explanation is that only still further, in some cases raising the proportion absorbed to 90%, which closely approaches normality

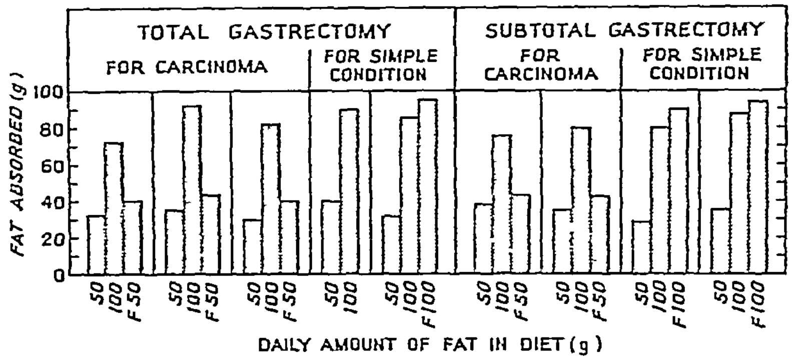

Fig 4—Amount of fat absorbed from different diets after gastrectomy F = fractional

These findings seem to be of considerable clinical importance, and they have lately been applied in the treatment of 2 patients, to find out whether the patients' general nutrition could be improved in this way and whether there were any adverse effects This presented some difficulties in practice, for it was necessary to keep the patients in hospital for a further month in addition to their stay of at least a month for routine investigations Only 2 patients agreed to this, but one of them gained 12 lb and the other 6 lb in the month There do not appear to be any adverse effects, and the daily number of stools is not increased In our experience these patients like a high-fat diet, but some other writers on this subject, for example Muir (1949), find that after partial gastrectomy many patients “go off fats” Naturally we have recommended this régime to patients discharged from hospital, and with some satisfactory results, but many complain that the present ration scales make it very difficult and often impossible to follow unless sympathetic members of their family are willing to give up their fats

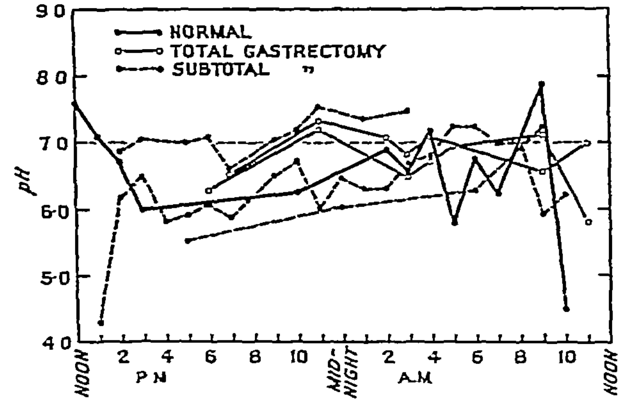

Fig 5—Values of pH in upper jejunum in 2 cases of total and 3 cases of near total gastrectomy for carcinoma and in 1 normal person

Our present view is that the “dumping syndrome” mechanism is responsible for the defective fat absorption When a meal is dumped mechanically en masse into the jejunum, the pancreas does not receive either “neurogenic” or “hormonal” warning until too late, whereas when the fat is given in multiple small meals (“fractionation”), even if the first meal misses the pancreatic enzymes, almost certainly the remainder will be more fortunate because they will utilise the enzymes secreted as a result of the stimulus of the preceding meal. This might be called “pancreaticocibal asynchrony”

Experiments have been undertaken with duodenal and upper jejunal intubation in order to assess pancreatic function and intestinal pH (fig 5) Unfortunately, no satisfactory quantitative test could be devised, but qualitatively it can be said that normal enzymes are present The pH findings have proved of great interest because many writers in the past referred to a “stabilisation of pH” following radical gastrectomy and suggested that it might be responsible for the poor absorption of ‘ferric” iron, resulting in anæmia From fig 5 it will be seen that the upper jejunum seems to be mainly “acid”, one case even had a pH of 4·2 at one stage in the day

In order to dispose of the possibility of an obstruction to the absorption of neutral fat through the lymphatics or even the cisterna chyli, blocked as a result of the operation, chylomicrograms were done on a series of cases with results shown in fig 6, these can, I think, be considered normal, though slightly delayed

Bowel motility, judged by giving barium with normal meals, appeared to be normal in the few cases tested, and so also were the cholecystograms and liver function tests.

BLOOD PICTURE

Anæmia

Iron deficiency was apparently not present in our cases except in the immediate postoperative period, when it seems to be directly due to loss of blood before and at operation and the consequent depletion of iron stores When the depletion is corrected the patient remains stable On the other hand, other workers—e g, Ransom (1948)—have often pointed out that “hypochromic microcytic anæmia” is a common sequel to gastrectomy

Macrocytosis

Macrocytosis in the peripheral blood was present in 11 of our cases—about a quarter of the total. This is intriguing but of academic interest only, since none of our patients has had an associated anæmia requiring treatment This subject was investigated by estimating the mean corpuscular volumes (M.C.V.) and noting the general appearance of cells in stained films Price Jones curves were not done, but we are assured by our hæmatologist that the M.C.V. results given in fig 7 almost certainly represent an “understatement,” since these cells are “thinner” than normal. Bone marrow biopsies were made in most of the cases and showed uniformly that the source of the macrocytosis is the macronormoblast in a hypercellular marrow

Even more interesting are the cases that show a waxing and waning macrocytosis, including those with a preoperative macrocytosis that returns to normal

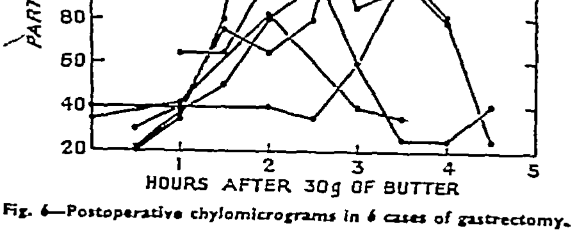

Fig. 6—Postoperative chylomicrograms in 6 cases of gastrectomy.

his normal level Among the possible causes of these changes we have considered the following

(1) Difficulties of ingestion—e g, dyspepsia and dysphagia
(2) Defects of absorption
(3) Disturbance of fluid balance
(4) Increased utilisation of food

Up to now only the first two have been seriously investigated, the third is strongly suspected to play a part, though without direct evidence The follow up findings in the 33 cases are summarised in table I

DIFFICULTIES OF INGESTION

Capacity for Food —The total amount of food taken in 24 hours was almost invariably less than before operation, it tended to increase with time but rarely reached normal The intake was usually rather larger after subtotal than after total gastrectomy An important finding was that 5 patients ate "more food than they had ever eaten in their lives," by the simple expedient of taking frequent small meals, as a result, these 5 patients had returned to about their normal weights

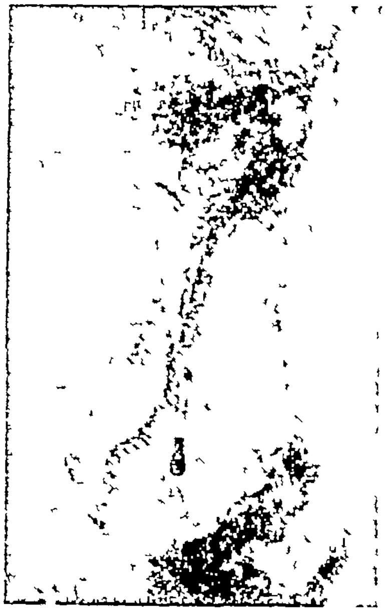

Fig 1—Balloon introduced into efferent jejunal loop; before infection

Dumping Syndrome —In the 20 "mild" cases there was postcibal fullness, not severe but definitely limiting the patient's capacity for food The 6 "severe" cases also showed evidence of autonomic stimulation, such as sweating, palpitation, or faintness, and in 1 case actual loss of consciousness The mechanism of these symptoms was established in 2 severe cases by the introduction of a balloon into the efferent jejunal loop (fig 1), when the balloon was inflated the dumping symptoms were exactly reproduced twice in one patient and once in the second This had previously been reported by Alvarez (1940)

Dysphagia —Except in the cases of frank vitamin B deficiencies (see below), dysphagia was rarely a distressing symptom and patients seldom complained of it except on direct questioning Where the dysphagia appears to be related to the regurgitation of intestinal juices, the type of œsophago intestinal anastomosis done probably plays a part in its causation On the whole, we now believe that the Roux Y anastomosis is more satisfactory The simple loop technique, even when combined with an entero anastomosis, seems liable to produce manifestations of regurgitation One patient in this series had an œsophagoduodenal anastomosis, and this has been followed by a persistent and highly disabling œsophagitis

TABLE II—INCIDENCE OF METABOLIC DEFECTS IN 40 GASTRECTOMY PATIENTS

Type of gastrectomy	No of cases	Deficient fat absorption	Vitamin B deficiencies	Macrocytosis	Iron deficiency
Total					
For carcinoma	15	8	5	6	0
For other conditions	4	3	1	3	0
Near total					
For carcinoma	13	7	3	1	0
For other conditions	6	3	0	1	0
Whole series	40	21/21*	9/32†	11/32†	0/25‡

* Only 21 cases were submitted to fat absorption tests
† Excluding 5 patients who died within five days of operation and 3 who did not attend for follow up
‡ Excluding 12 patients who died within three months of operation and 3 who did not attend for follow up

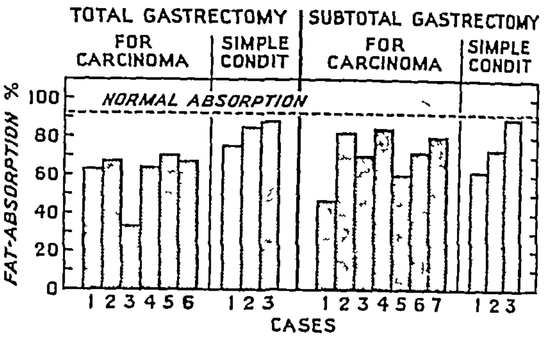

Fig 2—Fat absorption of patients on diet containing 50 g fat daily, three months after gastrectomy

Diarrhœa was invariably present in the early stages after operation, but it was not a distressing symptom and within three months it usually settled to 1 or 2 stools a day

Constipation was unusual, but it was very troublesome in 2 patients during their fat balance tests

DEFECTS OF ABSORPTION

Steatorrhœa

It will be seen from table II that steatorrhœa was demonstrated in all the cases that were thoroughly investigated by giving diets of known fat content (usually 50 g daily) over six days and collecting the stools during the last 72 hours This régime was repeated roughly at three month intervals to note the effect of time

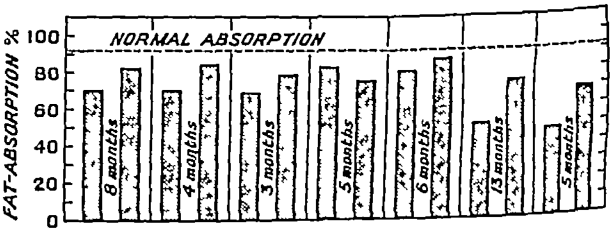

Fig 3—Effect of time on fat-absorption of gastrectomy patients on diet containing 50 g fat daily

In fig 2 the degrees of fat absorption defect in the four groups are compared The series is too small for definite conclusions to be drawn, but the defect seems to be greatest after total gastrectomy for carcinoma The effect of time is illustrated in fig 3, where all but 1 of the 7 cases show some improvement, though none has yet reached a normal level of absorption

The most significant experiments were those comparing the effects of doubling the amount of fat in the diet (giving 100 g instead of 50 g a day), "fractional" feeding of fat (i e, giving small amounts in hourly feeds throughout the day), or a combination of (1) and (2) Fig 4 shows the results in 9 typical cases

It seems clear from these results that doubling the fat content of the diet at least doubles the amount of fat absorbed Dividing the daily ration into small hourly feeds also raises the percentage of fat absorbed And a combination of the two methods improves absorption

PREVENTION AND TREATMENT OF TRAVEL SICKNESS WITH PROMETHAZINE CHLOROTHEOPHYLLINATE

JOHN HARPER
M.B Belf., D.T.M & H
OF THE MEDICAL TRIALS UNIT, MAY & BAKER LTD

TRAVEL sickness is not a disease but a normal physiological reaction to various types of oscillatory motion, at least 90% of normal people are susceptible to it in some degree (Morton et al 1947), and its severity and duration are conditioned by many psychic, somatic, and environmental factors The difficulties in assessing the value of any remedy for travel sickness have been emphasised by all who have written on the subject Objective criteria are few, there is extreme personal variation among the victims, and there is the added complication of spontaneous recovery in a matter of days

REMEDIES USED PREVIOUSLY

The many remedies recommended and used for sea sickness include compounds acting on the central nervous system, such as barbiturates, caffeine, and amphetamine, those acting on the autonomic nervous system, such as atropine and other alkaloids, and local anæsthetics such as chlorbutol and cocaine During the late war premeditated trials, in which many of the peace time variables were eliminated or overcome, were designed and made on a large scale (Noble et al. 1947) The results showed that hyoscine hydrobromide in doses of 0 6 mg (gr $^1/_{100}$) was effective (Holling et al. 1944) and safe, even under tropical conditions (Hill and Guest 1945)

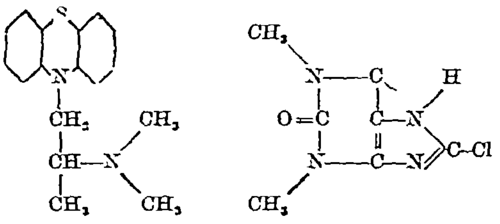
Many of these war time trials of solanaceous alkaloids and barbiturates were conducted with the particular object of preventing seasickness in fit trained men exposed for short periods in landing-craft and other small vessels The conditions were not therefore comparable with those experienced by civilian passengers on longer voyages

Chance and the independent observations of McEvedy (1949) and Gay and Carliner (1949) have led to trials of other compounds under conditions more like those of civilian travel. McEvedy, while in charge of the sick bay of a British troopship, observed that patients treated with anti histamine compounds were less affected by seasickness than other patients He showed, by a planned comparison of 'Anthisan' and hyoscine, that anthisan was at least as acceptable a remedy as hyoscine and was free from some of the disadvantages of that drug Gay and Carliner, working in an allergy clinic in North America, were investigating the possible value of 'Dramamine' in hay fever and urticaria, when one of their patients noticed that, though she had suffered from car sickness all her life, she could control it completely if she took 50 mg of the drug a few minutes before boarding a street car These workers then investigated the effects of dramamine in cases of motion sickness and later in cases of seasickness Trials were conducted in a North Atlantic troopship, groups of subjects living under the same conditions were studied, and controls were given lactose Further trials of anti histamine drugs include those of Rust and Fosberry (1949) on dramamine, Beaumont (1949) on anthisan and 'Phenergan,' Ambrus and Ambrus (1950) on phenergan in seasickness, and of Strickland and Hahn (1949) on dramamine in airsickness A summary of dramamine trials under various conditions has been published by Shaw (1950), and Wright (1950) has recently compared older remedies of the barbiturate hyoscine group with some anti histamine drugs and their derivatives both prophylactically and therapeutically under troopship conditions Scandinavian workers have also reported similar work, Santesson (1949), using 'Amosyt' which is similar to dramamine, has recorded his findings in a variety of conditions including sea, train, car, and air sickness, and Engquist (1950) has described the use of 'Lertigon,' the hydrochloride of a phenthiazine base very similar in composition and action to promethazine chlorotheophyllinate known as 'Avomine'

The prevention and treatment of seasickness with avomine during four crossings in a large North Atlantic civilian passenger liner in the winter of last year is described here

PHARMACOLOGY

Avomine, which is chemically N (2 dimethylamino-n propyl) phenthiazine 8 chlorotheophyllinate (i e, the 8 chlorotheophyllinate of promethazine), has the following structural formula



Promethazine　8 chlorotheophylline

It is a white powder sparingly soluble in water and was prepared for use in small uncoated tablets of 10 mg and 25 mg (equivalent to 56 2% promethazine) for oral administration

The clinical pharmacology and practical applications of promethazine hydrochloride (phenergan) have been described by Bain et al.(1948) and by Bain (1949) It has a powerful protracted anti histamine action as well as other effects, which include local anæsthesia and reduction of capillary permeability Like many of the other anti histamine drugs it has a sedative effect which varies from person to person, but this seldom lasts as long as its anti histamine action

Cusic (1949), in an attempt to counteract the drowsiness which may limit the applications of anti histamine drugs in some cases, tried the effect of combining a xanthine derivative with an anti histamine grouping Many of these salts were unstable, but the 8 chlorotheophyllinate was an exception and formed a stable salt Recently Mitchell (1950) has described some preliminary research which suggests that the introduction of 8 chlorotheophylline, apart from altering the incidence of side effects, may actually alter the anti emetic action of the anti histamine grouping

CLASSIFICATION OF CASES

It is difficult to draw an objective dividing line between prevention and treatment in a condition in which the victim passes, by imperceptible stages, varying in sequence, duration, and severity, from a state of well-being to one of abject misery And it is revealing to note how few people, even among those who know of their high susceptibility to motion sickness, seek medical advice on embarkation or soon after The small number of people asking for preventive treatment is extremely regrettable in view of the findings of Quigley et al. (1943) and Wolf (1943) which indicate that if prevention of nausea by oral drug administration is to be attempted, it should be commenced early—preferably before even

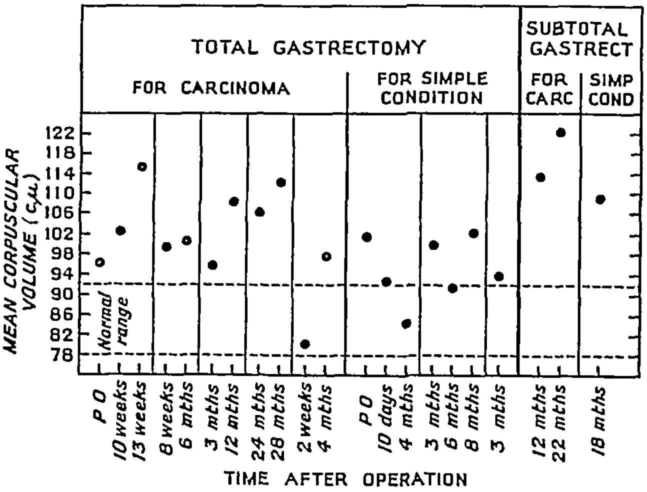

Fig 7—Mean corpuscular volume in 10 cases at various times after gastrectomy P O = postoperative

after operation More detailed preoperative investigation, I feel, would reveal many more instances of incipient macrocytosis, particularly in the carcinoma group In one recent case where an œsophagojejunostomy was performed for a simple stricture, leaving an intact normal stomach in situ, a macrocytosis developed postoperatively

There seems no doubt that this blood picture commonly accompanies other types of steatorrhœa—e g , idiopathic steatorrhœa and sprue—and also vitamin B deficiencies In the present series 6 patients with vitamin B deficiency were found to have macrocytosis and the other 5 are strongly suspect but no absolute blood counts were done because they occurred very early in the series

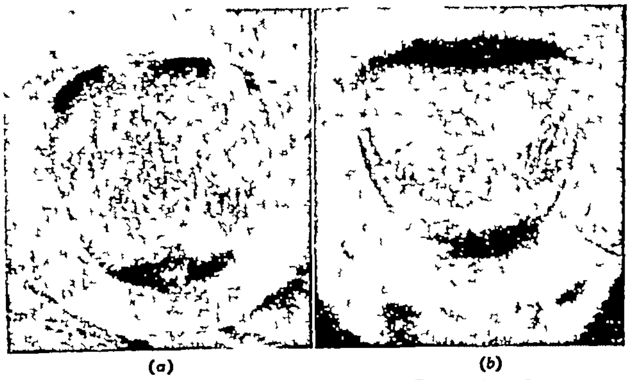
The question arises whether our present cases of macrocytosis will become megaloblastic some years after operation, a sequel reported by several surgeons and well illustrated by Moynihan's famous case

DEFICIENCY OF VITAMIN B COMPLEX

The present series includes 9 cases of vitamin B deficiencies The diagnosis was made on the clinical observation of glossitis (fig 8) (often ulcerative), pharyngitis, œsophagitis, cheilosis, corneal hypervascularity, and (in 1 case) generalised rash, together with the response to nicotinic acid, riboflavine, and occasionally pantothenic acid The onset has been on the 6–10th postoperative days, except in 2 cases which started three months and one month after operation, the last case coinciding with a large empyema

All the cases that were recognised were cured, but 2 patients early in the series died with gross pharyngitis and œsophagitis so severe that nutrition became impossible

Our present routine is to give large doses of nicotinic acid and riboflavine before and after operation This has reduced the incidence of vitamin B deficiency, though 3 further cases have been encountered which illustrate the important effect of sepsis (fig 9) This seems to be bound up with what we now regard as the ætiology of the condition—rapid multiplication and migration of the organisms in the upper alimentary tract, and a consequent increased demand for the vitamin B complex If infection occurs elsewhere—e g , subphrenic space or pleural cavity—the demand will be even greater, and hence the common association of vitamin B deficiency in these cases with septic complications Thus we now give vitamin-B complex as a routine after gastrectomy, and if signs of vitamin B deficiencies still arise we search for and deal with any focus of sepsis and reinforce the dosage of vitamin B complex



(a) (b)

Fig 8—Glossitis due to deficiency of vitamin-B complex after gastrectomy (a) before and (b) a fortnight after, treatment with nicotinic acid and riboflavine.

We intend to extend our researches on the intestinal flora after gastrectomy both high up in the jejunum and in the colon, for in the colon steatorrhœa must play a part by permitting a gross proliferation of *Bact coli* where normally these organisms may be destroyed when their vitamin B complex is possibly reabsorbed

CONCLUSIONS AND SUMMARY

A great deal of work remains to be done particularly on the possible defect in the absorption of proteins and carbohydrates On the present evidence, which we have drawn almost entirely from studies of fat metabolism, it seems likely that the main causes of wasting after radical gastrectomy are poor capacity for food associated with the dumping syndrome , and malabsorption of fat

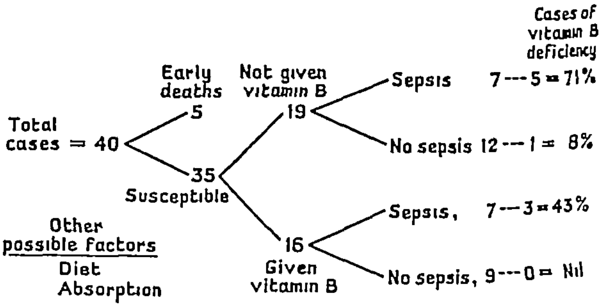


Fig 9—Effect of sepsis on incidence of vitamin-B deficiency after gastrectomy

The following " rational " treatment is recommended high fat diet (100–120 g of fat daily), with a correspondingly high caloric intake , multiple small meals so that fat is taken 8–10 times in the 24 hours The patient should not drink with meals and should avoid sugar, protein hydrolysates, and other substances capable of producing a high intrajejunal osmotic pressure, with drawing fluid from the bowel, and so causing further distension and perhaps inducing the dumping syndrome (Machella 1949) On this régime some patients in the present series have managed to eat more than their normal preoperative intake and have therefore gained weight

The blood picture after radical gastrectomy is characterised by a high incidence of macrocytosis No evidence of iron deficiency was found

Vitamin B deficiencies can be prevented by the routine administration of vitamin B complex and by the eradication of sepsis

The biochemical estimations were made in the biochemical department of the Queen Elizabeth Hospital and in the pharmacological department of the University of Birmingham I wish to thank Dr Garfield Thomas and Prof A. C Frazer for the advice and assistance rendered by them and their departments, and Dr A L P Peeney for help in hæmatology , Mr A. L d'Abreu, Mr A. Gourevitch, Mr B N Brooke, Mr D M Morrissey and Mr J L Collis, under whose care the patients were admitted, for their coöperation , and Sister Simpson and her nurses at the Queen Elizabeth Hospital for their care of these patients

References at foot of next column

seasickness (a prevention rate of 92%) leaving 4 cases (8%) in which prophylaxis was unsuccessful. These 4 failures included 2 patients who asked for treatment to be continued because they were bad travellers, 1 who admitted having had a "surreptitious" tablet of unknown strength from a friend, and 1 for whom the dose was obviously inadequate but in whom prophylaxis was eventually successful with 25 mg. twice daily.

Therapeutic Group

In this group of 274 cases all were treated with 25 mg. tablets, given two on the first day of treatment (one immediately and one at night) and one the next evening.

TABLE III—THERAPEUTIC GROUP

Direction of voyage	No. of cases	More than 1 visit only	More than 3 tablets only	More than 1 visit and 3 tablets	Treatment successful	Treatment unsuccessful
Out	216	2	7	18	27	189 (87.5%)
Home	58	0	5	3	8	50 (86.2%)
Total	274	2	12	21	35	239 (87%)

In 239 (87%) treatment was successful with one visit and three tablets, and the remaining 35 (13%) required further treatment. 2 required an additional visit only, 12 required additional tablets only, and the remaining 21 required both additional tablets and an additional visit. Among these 35 are included 2 patients visited to investigate reports of possible side-effects, 9 requesting, or considered likely to benefit from, prophylactic treatment for the remainder of the voyage, 4 who vomited the first dose, and 20 who had relapsed after a period of freedom from symptoms and asked for further treatment.

SIDE-EFFECTS

In only 3 cases were there any side-effects which might possibly be related to the treatment.

Case 1.—A frail elderly woman had one 25 mg. tablet at night. The next morning vomiting had stopped, nausea had gone, and she ate a light breakfast in bed. When dressing about two hours later she felt dizzy and could not stand, but after lying down for a few hours she became completely normal.

Case 2.—A well-built young man was confined to bed for three days before calling for help. He had spent the whole of three previous transatlantic voyages in bed. Two 25 mg. tablets were given at 6 P.M., because he was reported to have slight streaks of blood in his last vomitus, and two were left for the next day. He slept until 1 A.M. and then took his remaining two tablets. Nausea and vomiting had gone the next morning and he got up despite severe giddiness lasting some hours.

Case 3.—An elderly woman whose vomiting had been controlled by self-administered dramamine was unable to be up and about, because of drowsiness and dizziness; she was given 10 mg. at night and the next morning while on the sun-deck—five decks above her cabin—she fainted. She recovered spontaneously after lying down for a few minutes.

COMPLICATED CASES

Two types of cases are grouped under this heading: those in which motion sickness was superimposed on some other condition, and those in which other remedies had already been used. The first group included 7 pregnancies, 4 cases of diabetes, 1 systemic vaccinia reaction, 1 patient taking phenobarbitone after operative removal of a brain tumour, 1 person who took anthisan to relieve migraine, 1 case of myxœdema, 1 severe hypertensive with orthopnœa, and 1 woman who had recently undergone a complete perineal repair. In all these cases seasickness was successfully prevented with routine doses.

The second group consisted of 44 patients who were treated because other remedies, either self-administered or prescribed by their doctors ashore or afloat, had failed, or who had asked for treatment because of residual symptoms of seasickness or obtrusive and unpleasant side-effects of previous medication. It included 25 persons who had taken other anti-histamine compounds or their derivatives and 17 who had taken one or other of the solanaceous alkaloids; in many of these cases the original drug had been taken irregularly, and often in inadequate doses, after the onset of the premonitory symptoms and even later. Among those who had taken the anti-histamine compounds, nausea and vomiting were controlled to a large extent, but those requesting treatment were confined to their cabins because of drowsiness, dizziness, or headache; one woman was extremely agitated, and another so drowsy and disorientated that she said with some feeling that she would rather have been sick. Among those who had taken alkaloids, nausea and vomiting were often still present, and one woman, a nurse, presented the typical picture of belladonna poisoning—hot flushed skin, dry mouth, and widely dilated pupils. All these cases at the first visit were given avomine in routine prophylactic or curative doses, and none required any further treatment either for seasickness or for side-effects.

DISCUSSION

How or why the anti-histamine compounds and their derivatives act, not only in motion sickness but also in a wide range of conditions in which nausea and vomiting are prominent presenting symptoms, can be little more than armchair speculation until the fundamental physiology of nausea and vomiting has been elucidated, and the various pharmacological actions and antagonisms of these new synthetic agents have been more surely assessed.

Their successful use in abolishing these symptoms suggests that the site and mode of action are more likely to be found in the blocking mechanism on the effector side of the reflex arc. Of interest in this connection is the clinical finding that dizziness, whether it be a residual symptom of seasickness or a side-effect of the drugs themselves, may remain after the nausea and vomiting have been abolished. Hill (1937) has noted that, in some cases of seasickness treated with amphetamine, partial cures were obtained in which headache and dizziness were abolished while nausea remained. Whether the agent "blocked" be histamine, acetylcholine, or some other substance of importance to the physiological economy of the central or autonomic nervous system, time and experiment must be left to say. In the meantime, the drugs we have are very valuable in controlling nausea and vomiting and so preventing biochemical imbalances and dehydration which result from uncontrolled vomiting.

SUMMARY

'Avomine' (promethazine 8-chlorotheophyllinate) is a safe and effective remedy for seasickness.

In the dosage recommended its side-effects are insignificant.

In 92% of cases treated prophylactically and at least 87% of cases treated therapeutically success was achieved with three tablets of 25 mg. given (but not all taken) at one visit.

Prevention or treatment does not seem to interfere in any way with the normal mechanism of adaptation to the disturbing motion.

I wish to thank the directors and the medical superintendent of the Cunard Steam Ship Company Ltd., whose kind coöperation made this trial possible; the ship's doctors, nurses, and dispensers for advice and help; and the stewardesses and stewards for their willing assistance.

References overleaf

premonitory symptoms have appeared In this present trial an attempt was made to divide those passengers who called for aid into prophylactic and therapeutic groups The prophylactic group includes (1) those persons who came for advice before or soon after sailing, (2) those who came at the threatened approach of rough weather, and (3) those who came in the initial stages of their reaction to the ship's motion, when their symptoms were confined to malaise

Most of the therapeutic group were in the later stages of seasickness, and many of them could not leave their cabins, having failed to respond to the ministrations of friends and cabin staff, various forms of self medication, or the remedies prescribed by their own doctors

ROUTINE OF TREATMENT

Dose—Tentative variations of dose from case to case in the early stages of the first outward voyage showed that avomine 10 mg once, or even twice daily, was adequate in some cases but not in others It was also found that avomine 25 mg even when given twice daily was unexpectedly free from the usual anti histamine side effects From these encouraging preliminary observations the routine dosage was adopted of one 25 mg tablet each evening at bedtime for prevention, and, in established cases, two 25 mg tablets on the first day (one when the case was first seen and one the same evening), and a third 25 mg tablet on the evening of the second day

Administration—The tablet was to be placed on the tip of the tongue and rapidly washed down with a small drink In established cases, the patient was advised to stay in bed for one to two hours after the first dose to minimise the chances of the tablet not being retained Otherwise no restrictions were imposed, the patients were encouraged to get up and about as soon as they felt able, and to eat what and when they fancied Many patients were able to retain not only fluids within an hour but also solid food soon afterwards If, as occasionally happened, the first dose was not retained it was repeated immediately The small size of the tablet used, and the ease with which it was swallowed, was appreciated by those in whom nausea was a prominent symptom, and by those who had had experience of larger tablets, or of several tablets at once, on other occasions Children aged 5 years or more were able to take the 10 mg tablets without difficulty and without any unpleasant side effects, some of the heavier children aged 9–12 years were given the same dose as adults from the start Though suppositories had been prepared in readiness, the administration of avomine otherwise than by mouth was not found necessary, and parenteral fluids were not required in any case All patients—the majority of them tourist class—were successfully treated in their cabins, none requiring transfer to the ship's sick bay

Supervision—Since the cases were not evenly spread out over the duration of each voyage but concentrated into the second and third days (out of 372 cases on four voyages, 221 were first seen on the second day out of port and 106 on the third day out), administration of each dose, either personally or by the ship's medical staff, was impracticable To ensure that patients, if not rapidly relieved, would be seen again, and to reduce as far as possible surreptitious transfer of tablets from person to person, only three tablets were left at the first visit

ASSESSMENT OF RESULTS

Rigid assessment of a remedy for seasickness under peace time North Atlantic travel conditions is unsatisfactory for many reasons It is difficult to control the almost endless variables Patients may not cooperate, or if they do and are quickly cured, they may never be seen again Personal follow up of a large number of cases is impracticable when the voyage takes only 5–6 days and most of the patients are seen in the first two days The use of an inert substance as a control is unjustifiable in the case of fare paying passengers who are either on long planned voyages or important business trips Despite these difficulties it was hoped that regular reporting by cabin staff, limitation of tablets to three at a time, and check up of those still in their cabins on the later days would enable some estimate to be made of probable failures Though there are many obvious loopholes the criteria of cure—or perhaps, more accurately, of failure to control—have been taken as the need for more than one visit, or more than three tablets, or both These criteria are far from ideal but provide some measure of the success of any treatment if only from the somewhat selfish point of view of the sick-bay A single visit, at which three tablets are prescribed is not an "unsuccessful" course of treatment for established motion sickness Further visits or additional tablets do not necessarily mean that the original treatment failed, they may indicate a relapse or a request for preventive treatment for the remainder of the voyage The fact that one tablet prophylactically on each of three successive nights, or three tablets therapeutically over 24–36 hours, proved adequate, without continued medication, in such a high proportion of cases suggests that this treatment does not interfere with the normal mechanism of adaptation to the disturbing motion but "blocks" the annoying symptoms so often experienced during the process

ANALYSIS OF RESULTS

The data collected on 372 cases were considered complete enough for tabulation, but in the final tables 48 of these are not included Of this group of 48, 26 were children of various ages Those aged over 5 years had avomine 10 mg, and those aged under 5 years, phenergan 5 mg, 15 were adults treated with 10 mg tablets in the early dosage estimations, and the remainder were given 10 mg doses only, on account of complicating factors or doubt about their symptoms being due to seasickness This leaves 50 cases in which avomine was used for prevention, and 274 in which it was used for treatment

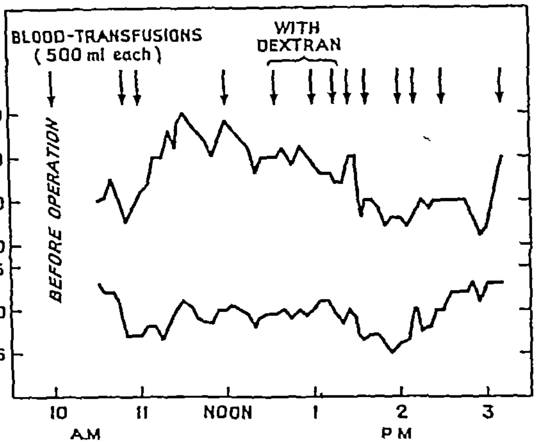

Fig 9—Blood pressure and right auricular pressure during hindquarter amputation in a man aged 59

arterial blood pressure at the end of a total gastrectomy lasting five hours was virtually the same as it was during the pre anæsthetic period On four separate occasions during the operation the mean blood pressure fell to 75, 90, 85, and 78 mm Hg, but on each occasion it was rapidly restored by blood transfusions of 175, 325, 300, and 300 ml at rates varying from 90 to 325 ml a minute The greatest rise in right auricular pressure was 11 cm of saline solution and was only temporary

Fig 9 shows the blood pressure responses and the right auricular pressures in a patient transfused intra arterially The mean blood pressure at the beginning of the operation was only 70 mm Hg At the end of a lengthy major operation the mean blood pressure was 80 4 litres of blood and 1 5 litres of dextran were given intermittently during the operation The right auricular pressure was never raised above its pre anæsthetic level

CONCLUSIONS

The replacement of rapid and severe blood loss at rates similar or equal to the rate of loss may, on occasion, be a life saving procedure Our experience leads us to state that transfusion at rates up to 350 ml. per minute can be effectively achieved with a rotary pump and is safe, provided that care is taken to ensure that not more than 70% of the estimated blood loss is replaced rapidly A raised venous pressure is a warning to stop the transfusion

SUMMARY

The rationale is given for the use of rapid transfusion Circulatory collapse from severe hæmorrhage—e g, during operations on the heart, large blood vessels of the body, and vascular tumours—must be rapidly treated if irreversible shock is to be avoided

The fluid mechanics and dynamics of transfusion are presented

Limitations of rapid replacement by standard gravity techniques are explained only 70 ml. of stored blood can be transfused intravenously in one minute through a single large Hamilton Bailey cannula if gravity alone is used and the height of the reservoir is 4 ft (the usual height of a transfusion bottle above a patient)

Blood replacement at a rate greater than 70 ml. per minute requires either multiple transfusions or some form of pressure delivery

The use of a rotary pump and a large Hamilton Bailey cannula allows delivery of 350 ml. of blood per minute at a pressure of 440 mm Hg

A simple straight silver cannula of special design allows delivery of 350 ml of blood per minute at a pressure of 120 mm Hg

The dangers of rapid pressure transfusion are discussed Replacement at a rate of 350 ml per minute increases the normal stroke volume of the heart by only about 9% and has proved safe A raised jugular venous pressure is evidence of overloading of the circulation and is an indication to stop the transfusion The risk of air embolism is minimal if a rotary pump is used, and hæmolysis is not a direct complication of the method Local venous thrombosis is a common sequel of pressure transfusion but is not serious

Not more than 70% of the estimated blood loss should be rapidly replaced in the presence of vasoconstriction The remainder should be given slowly

Pressure transfusions were given to twelve patients undergoing major surgery, intravenous and intra arterial routes were used Restoration of blood pressure followed rapid replacement of blood and was achieved without untoward sustained increases of pressure in the right auricle of the heart

The rotary pump has been made available to us by the kindness of Mr Schranz, of the Genito Urinary Company, London, W 1.

SICKLE-CELL ANÆMIA IN GREECE

C Choremis

RESIDENT MEDICAL OFFICER

ST SOPHIA S HOSPITAL FOR CHILDREN

Sickle cell anæmia is usually regarded as essentially peculiar to the Negro race Sporadic cases have been described in white people, but in many of them it has been impossible to rule out admixture with Negro blood Such cases have been mostly in Americans of Greek or Italian origin (Wintrobe 1946), but a few cases have also been described in Italy (Powell et al. 1950) and Greece (Makrycostas 1940, Zaberdinos 1950, Comninos et al. 1950)

We now report the discovery of foci of sickle cell anæmia in villages situated around Lake Copais * It was so common that the villagers gave it a special name —*kokkali*, from *kokkalo* meaning "bone" *in colloquial* Greek, probably because of the characteristic pains in the joints

We visited one of these villages, Petromagoula,† and examined 11 children and 10 of their parents, indicated to us by the local physicians Besides a careful clinical examination we made blood counts and examined their blood in dry smears and wet preparations sealed with soft paraffin Sickle cells were found in the wet preparations from 12 persons, of whom 9 were children The case records are summarised below and easy flow. Acute bends or kinks in the tubing are to be avoided, and the drip nozzle in the drip chamber should be of the same internal diameter as the rubber tubing of the system. Ideally, the cannula or needle should slope gently, as in the French's type of needle, while the connecting tubing should fit over the outside of the needle shank.

---

* *Copais was a swamp* which was dried out by an English company a few years ago The neighbouring villages comprised one of the most malaria stricken areas of Greece

† The ancient town of Orchomenos

Such recommendations are equally applicable both to rapid and to slow transfusion techniques, and their adoption would tend to minimise the risk of spontaneous stoppage in slow drip transfusions (Walton 1947).

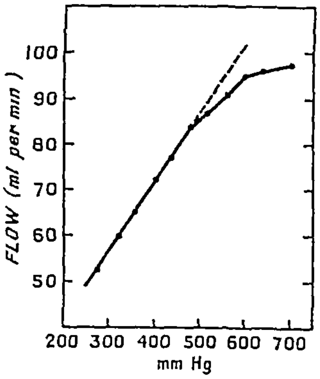

Fig 6—Flow through Luer needle 20 g × 1½ in, showing critical pressure beyond which rate slows.

Provided that these refinements of technique are adopted, then with the usual pressure of 100 mm Hg (or a head of water 4 ft—the average height of a transfusion bottle above a patient), 125 ml of saline solution, or 70 ml of stored blood, can be delivered in a minute through a large Hamilton Bailey cannula. To increase this rate of transfusion it is necessary either to increase the pressure or to use more than one cannula. If the pressure is raised to 280 mm Hg, 350 ml of saline solution can be delivered in one minute, to deliver blood at this rate the pressure must be raised to 440 mm Hg. If the pressure is not increased above 100 mm Hg, four large Hamilton Bailey cannulæ are needed to deliver blood at a rate of 280 ml a minute.

The flows referred to occur only if there is free outflow beyond the cannula. Vascular spasm will cause a considerable diminution in rate of the transfusion if gravity alone is used. For this reason we prefer to use a rotary pump, modified from Riddell (1939), and connected by rubber pressure tubing to a cannula of silver tubing 0·063 in in internal diameter. With this equipment (fig 7) a flow of 350 ml of blood per minute can be obtained at an operating pressure of 120 mm Hg, and the rate of flow is not affected by variation in resistance to the outflow. Such a system may be used equally well for intravenous or intra-arterial transfusion.

DANGERS OF RAPID TRANSFUSION

The risk of overloading the heart by a high-speed transfusion is not so great as might first appear, for, even if the rate of transfusion is 350 ml a minute, the normal stroke volume of the heart is increased by only some 9%, and, when the stroke volume has become less than normal as a result of hæmorrhage, the extra amount of blood provided by the transfusion will hardly do more than make up for the acute deficiency.

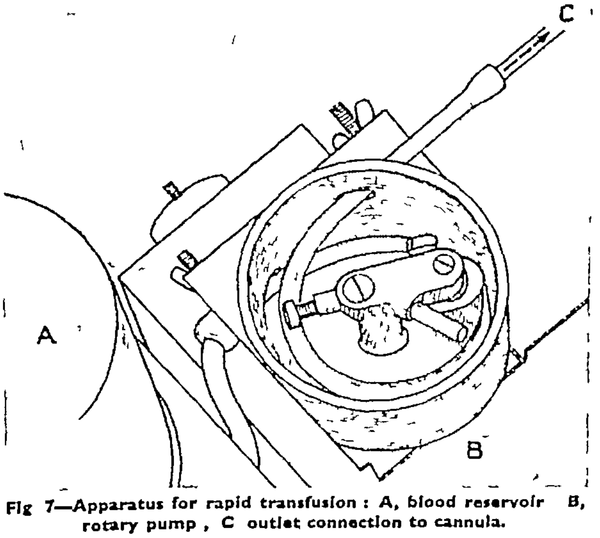

Fig 7—Apparatus for rapid transfusion: A, blood reservoir. B, rotary pump, C outlet connection to cannula.

The danger of overloading the circulation by excessive transfusion has been re-emphasised by Holden et al (1950). A rapid increase above normal in the total circulating blood volume is reflected by a rise in venous pressure and may be followed by serious cardiac embarrassment, especially if the myocardium is unhealthy or ischæmic. To avoid such risk it is important to ensure that the amount transfused does not exceed the blood loss. A raised jugular venous pressure must be taken as a warning to stop the transfusion.

Glaser and Page (1948) have shown, in animals made hypotensive by hæmorrhage, that intra-arterial transfusion of blood in amounts not greater than 70% of the blood loss is sufficient to restore the blood pressure fully, if greater amounts are given in the presence of compensatory vasoconstriction, irregular cardiac action and cardiac failure may develop. This principle should be accepted for man, and only 70% of the estimated blood loss should be rapidly replaced, the remainder should be given slowly as vasoconstriction decreases and the patient's pallor disappears.

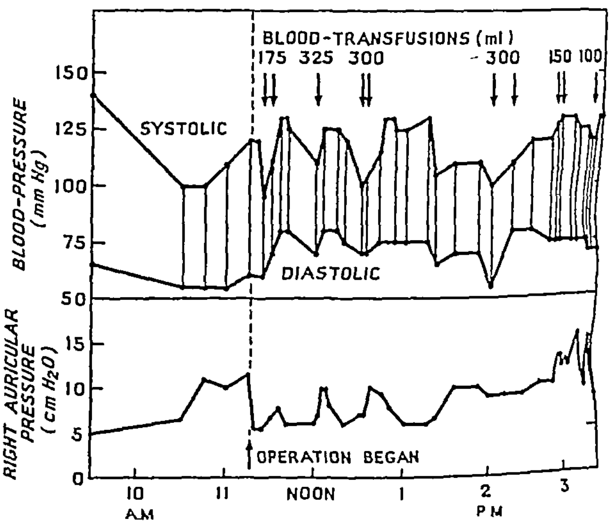

Fig 8—Blood pressure and right auricular pressure during total gastrectomy in a woman aged 68.

Hæmolysis resulting from the action of a rotary pump driving the blood is negligible, but we have, on one occasion, seen a severe degree of hæmolysis following transfusion of a large volume of stored blood, a sequel not necessarily due to the method. An excess of serum bilirubin may prove dangerous if pre-existing liver damage is present, but the risk of renal tubular blockage by blood pigments can be discounted if protracted hypotension is avoided and adequate fluid replacement is maintained (Robbins et al. 1950). Air embolism should never occur if the rubber tubing is sound and the reservoir is never completely emptied. Local venous thrombosis is a common sequel of pressure transfusion (Aird 1949), but in our experience it is not a serious complication.

PERSONAL EXPERIENCE

Twelve patients have been transfused with the cannula and rotary pump described. Nine transfusions have been given into veins at the elbow and three into radial arteries.

Fig 8 shows the blood pressure responses and the right auricular pressures in a woman, aged 68, who was transfused intravenously. It can be seen that the mean cases (leaving out the 5 from the neighbouring villages) to the previous 9, we have 15 children, or 0 25% of the population, suffering from sickle cell anæmia, compared with about 0 2% in the Negro race in America We are undertaking a study of the incidence of the sickle cell trait in Petromagoula Our findings up to the present moment seem to confirm the high incidence of the disease in this village

STENOSING TENDOVAGINITIS AT THE RADIAL STYLOID PROCESS

REVIEW OF THIRTY CASES

D A C REID
M B Lond, F.R C S

SENIOR REGISTRAR IN PLASTIC SURGERY, ROOKSDOWN HOUSE BASINGSTOKE, LATE SURGICAL REGISTRAR, HASLEMERE AND DISTRICT HOSPITAL

STENOSING tendovaginitis at the radial styloid process, though characterised by well defined signs and symptoms, is often wrongly diagnosed as "sprained wrist" (the patient often gives a history of injury), fracture of the scaphoid, neuritis, or rheumatism

De Quervain (1895) was the first to recognise and describe this condition, reporting 5 cases, 2 of which showed, at operation, the typical fibrous thickening of the tendon sheath He later reported 8 more cases, all of which responded to surgical treatment Hoffman (1898) also described the condition

Winterstein (1927) reviewed 154 cases, and Finkelstein (1930) recorded 24, all of which were operated on after failure of conservative treatment

Brown (1935) was the first to report a case in this country Clinically it appeared to be typical, but operation was refused The pain was relieved by immobilising the wrist in plaster, but recurred subsequently necessitating further periods of immobilisation

Burns and Ellis (1936) reported 28 cases

ÆTIOLOGY

Most of the patients are women and of the present series of 30 only 4 were males The ages ranged from 14 to 78, average 42 Of Finkelstein's (1930) 24 patients, 20 were women, and the majority were houseworkers The underlying cause appears to be chronic or repeated trauma, rarely is there a history of acute onset following injury The main incidence in women doing routine housework seems to be significant It is easy to understand that repeated trauma could cause inflammation of the tendons lying directly on the bone at the wrist and bound down by the extensor retinaculum Eichhoff (1927) explains that the cause in many cases seems to be a constantly repeated movement of the wrist, especially in adduction with the thumb fixed in grasping some object, when the affected tendons are stretched over the radial styloid process and maximally constricted This happens typically in wringing—an action very often used by the housewife

Of the 26 females in the present series 13 were housewives and 6 others were employed in housework, 2 were schoolgirls, and the remaining 5 included 1 nurse, 1 typist, 2 clerks, and 1 mill worker The 4 males were a sanatorium nurse (incidentally an amateur lawn tennis champion), a painter, a gardener, and a post office engineer Although no examples occur in this series, stenosing tendovaginitis is often seen in physiotherapists

Some of the patients attributed their symptoms to particular types of work—e g excessive gardening, machinery, and routine housework—and 10 attributed their symptoms to an injury

ANATOMY

The tendons affected are those of the abductor pollicis longus and extensor pollicis brevis muscles These two tendons have a common synovial sheath lying in very close contact at the wrist, the extensor being to the inner side of the abductor Where the sheath is thickened they lie in a groove on the lateral aspect of the lower end of the radius and are held close to the bone by the attachments of the extensor retinaculum

PATHOLOGY

As already described, the condition is thought to result from repeated trauma Initially this gives rise to œdema of the tendon sheath, which later becomes permanently thickened from dense fibrosis In the most advanced cases the thickened sheath has an almost cartilaginous consistence This thickening of the sheath compresses the tendons, which tend to become constricted and flattened Apart from this purely mechanical phenomenon, the tendons are not involved in the pathological process

The mesotendon is often thickened, and, together with the sheath enveloping the tendons, is often dull grey and less transparent than the normal synovial lining, this gives the tendons a dull lustreless appearance very different from the glistening transparent appearance of healthy tendons

On exposure at operation the affected part of the sheath appears as a pearly white thickening Microscopy of the hypertrophied sheath reveals fibrosis Sometimes there is slight cellular infiltration suggesting non specific inflammation Sometimes the thickened sheath is lined with granulation tissue, and the amount of fluid in the tendon sheath is often increased

CLINICAL FEATURES

The onset of symptoms is usually gradual The patient may attribute the disability to a sprain or some other trivial injury A continuous dull nagging pain, aggravated by movements of the thumb and wrist, is felt over the radial aspect of the wrist and extends to the dorsum of the thumb and into the forearm The site of maximal pain is localised by the patient accurately to the radial styloid process

Examination reveals a definite hard swelling felt on palpation over the radial styloid process, and not infrequently visible Passive movements of the thumb, particularly extension and abduction, and adduction (ulnar deviation) of the wrist, cause severe pain Excruciating pain on adduction of the wrist with the thumb flexed is pathognomonic, according to Finkelstein (1930)

DIFFERENTIAL DIAGNOSIS

Crepitus is not elicited on movement, this fact distinguishes the condition from traumatic tenosynovitis

True bony injuries—e g, fracture of the scaphoid—are excluded by radiography, which in stenosing tendovaginitis is usually negative, but Schneider (1928) reported finding calcium salts deposited near the lesion in some of his cases, and Brown (1935) found radiological evidence of periostitis—newly formed bone—just above the styloid process

Neuritis of the terminal branch of the radial nerve may give rise to a similar distribution of pain, but it will probably be associated with a corresponding area of hyperæsthesia Moreover the nerve can be palpated as it crosses to the dorsal aspect of the wrist $1^{1}/_{2}$ in above the radial styloid process This aggravates the pain, which is unaffected by movements of the thumb

CASE RECORDS

Case 1 —A boy, aged 18 months, was subject to periodic painful œdema of the forearms and lower legs His conjunctivæ were slightly icteric, and his mucosæ very pale The spleen was palpable three finger breadths below the left costal margin

Red blood cells numbered 3,700,000 per c mm , and white cells 6700 A dry blood smear (fig 1) showed conspicuous anisocytosis, with many target and oval cells A wet preparation examined after twenty four hours showed many sickle cells

Case 2 —A boy, aged 9 years, was subject to periodic œdema and pain in the joints and long bones His skin was pale The spleen was not palpable, but the liver could be felt two finger breadths below the right costal margin

Red cells 2,500,000 per c mm , and white cells 10,400 Dry blood smears showed moderate hypochromia and anisocytosis, with more than 40% target cells, 5–6% oat cells, and rare sickle cells Wet preparations showed sickle cells ten minutes after the blood had been taken

Case 3 —The mother of case 2 had no relevant past history , and physical examination was negative A wet preparation showed sickle cells after twenty four hours

The father's blood was also examined in a wet preparation, but no sickle cells were found, even after three days

Case 4 —A boy, aged 14, had had pains in the joints and long bones until four years ago Since then he had felt well His spleen was not palpable, but the liver extended three finger breadths below the right costal margin

Red cells 4,800,000 per c mm , and white cells 8000 A dry smear showed more than 50% ovalocytes, and rare target and sickle cells A wet preparation showed sickle cells

Case 5 —A boy, aged 1, had no relevant past history His spleen was palpable, one finger breadth, and liver two finger breadths, below the costal margin The liver was hard

A dry blood smear showed normal red cells A wet preparation, examined after twenty four hours, showed sickle cells

Case 6 —The mother of case 5 provided a wet preparation showing sickle cells Her husband was not examined

Case 7 —A girl, aged 5, was very pale and had had pains and œdema of the joints for a year Her liver was hard and palpable three finger breadths below the right costal margin

Red cells 2,200,000 per c mm , white cells 7600 A dry smear (fig 2) showed obvious anisocytosis, macrocytosis, and hypochromia, more than 20% target cells, and about 10% elongated red cells A wet preparation (fig 3) showed sickle cells

Case 8 —The twin sister of case 7 was subject to periodic fever and pains in the joints Her mucosæ were very pale and the conjunctivæ slightly icteric Cheek-bones prominent nose flat Her spleen was not palpable , but the liver extended three finger breadths below the costal margin and was very hard

Red cells 1,800 000 per c mm , and white cells 11,000 A dry smear showed obvious anisocytosis and 20–30% target cells A wet preparation showed sickle cells

Case 9 —A girl, aged 18, had had, since the age of 2 months pains in the joints, long bones, and abdomen Menstruation had started at the age of 15 One of her brothers had died with anæmia and pains in the joints Her liver and spleen were palpable two finger breadths below the costal margin

Red cells 4,000,000 per c mm and white cells 10,000 A dry smear was unsatisfactory A wet preparation (fig 4) showed sickle cells

Case 10 —The mother of case 9 provided a wet preparation which showed sickle cells , but the father of case 9 had no sickle cells

Case 11 —A boy, aged 12, had had pains in the joints for some years His liver was palpable two finger breadths below the costal margin, but his spleen was not felt

Red cells 3,300,000 per c mm and white cells 5800 A dry smear showed slight anisocytosis, rare target cells, and about 10% ovalocytes A wet preparation showed sickle cells.

Case 12 —A boy, aged 13, had had periodic pains in the joints and long bones The mucosæ were pale, and conjunctivæ slightly icteric Cheek bones prominent, nose flat. The spleen was palpable three finger breadths, and the liver one finger breadth, below the costal margin

Red cells 4,500,000 per c mm , and white cells 9600 A dry smear showed 4–5% target cells A wet preparation showed sickle cells

CONCLUSION

So great a number of cases of sickle cell anæmia among whites in a small area has never been described before, and raises several questions (1) Are malaria and chronic undernourishment ætiological factors in this disease? (2) What is the anthropological significance of the occurrence of sickle cell anæmia among Greeks? (3) In order to have sickle cell anæmia, is it indispensable to be homozygous for the sickle cell trait? (4) Can the sickle cell trait and the Cooley anæmia trait, which is so common among Greeks, interact and produce sickle cell anæmia in the carrier of both traits?

ADDENDUM

Since this article was completed we have found in Petromagoula 11 more children with sickle cell anæmia Of these 11, 5 were from neighbouring villages Only one parent was found to be positive for the sickle cell trait . The histories, physical findings, and dry smear preparations of blood were similar to those already described in the previous cases We also estimated total serum bilirubin, and found values above normal (0 6 mg per 100 ml) in 9 of these children, 5 of whom had values above 1 2 mg per 100 ml

Petromagoula has about 6000 inhabitants Thus if we add these 6 new

Fig 1

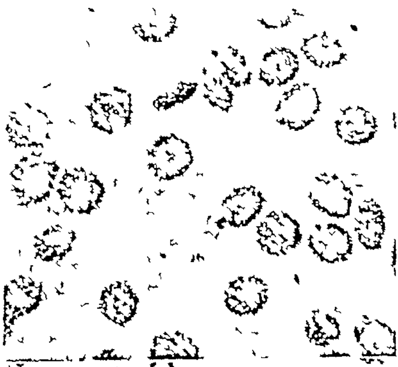

Fig 2

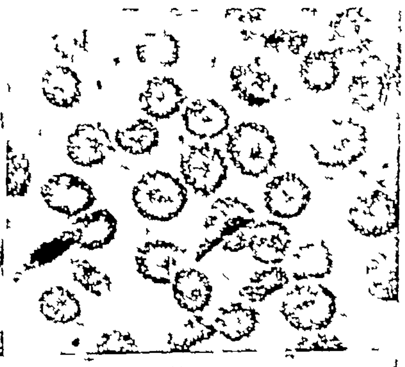

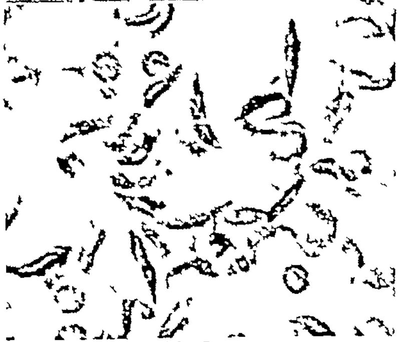

Fig 3

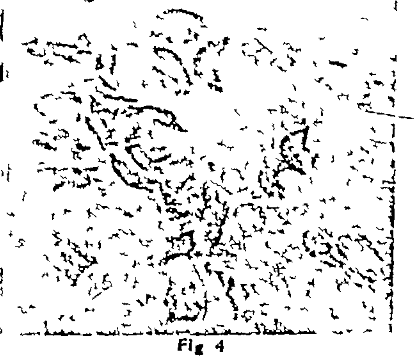

Fig 4

Fig 1—Dry blood smear from case 1 showing anisocytosis, with target and oval cells
Fig 2—Dry blood smear from case 7, showing anisocytosis target cells and oat cells.
Fig 3—Wet blood preparation from case 7, showing sickle cells.
Fig 4—Wet blood preparation from case 9 showing sickle cells

The results of surgical treatment are excellent

A case is also described in which a similar condition affected the flexor carpi radialis tendon at the wrist

I am extremely grateful to Mr Gerald N Golden, F.R.C S, for permission to publish his cases and for his help in preparing this paper

"TENNIS THUMB"

TENDINITIS WITH CALCIFICATION IN FLEXOR POLLICIS LONGUS

MICHAEL C OLDFIELD
M.B.E D.M. M.Ch Oxfd F R C S
SURGEON, GENERAL INFIRMARY AT LEEDS

ACUTE tendinitis with calcification in the supraspinatus and other tendons near the shoulder-joint is fairly common, and has been recognised since Painter's original account of the condition in 1907 and Wrede's confirmation of it in 1912 But calcification near the insertion of other tendons has been less often reported

CASE REPORT

History—My patient was a schoolgirl aged 15, who was right handed During the summer of 1949 she was in her school tennis team and played strenuously and often. Before the end of the term she noticed ' a lump under the ball of the right thumb At first it did not cause any pain, nor did it interfere with tennis or writing It gradually increased in size, and she noticed that it looked white ' Later it became tender and caused discomfort when she was gripping her racquet At the end of the term she went on holiday to France for three weeks Though she only played tennis three times while she was there the lump remained tender

On returning home, she had acute tonsillitis and was in bed for ten days After recovering from this she returned to school One day quite suddenly while she was doing lessons, she noticed that her thumb was generally swollen In the evening it became more swollen and painful Pain was so severe during the night that she could not sleep and her mother poulticed her thumb but the pain became worse Next day treatment with intramuscular procaine penicillin was started

Examination (Sept 26 at Dewsbury Infirmary)—The patient was in excellent general condition Temperature 98°F, pulse rate 86 respirations 24. Her right thumb was held in semiflexion and was generally swollen and inflamed The redness, induration swelling, and tenderness were greatest on the volar aspect Flexion and extension at the inter phalangeal and metacarpophalangeal joints were limited and painful The movements of the other fingers and wrist were unaffected There was no swelling or tenderness in the palm or above the wrist The supratrochlear and axillary glands were not tender nor enlarged

X ray examination of the right thumb showed irregular calcification in the course of the flexor pollicis longus tendon over the proximal phalanx and the base of the distal phalanx (fig 1) X ray examination of the left thumb and chest revealed no abnormality The erythrocyte sedimentation rate (Wintrobe corrected) was 1 mm. in 1 hour The Wassermann and Kahn reactions were negative

Treatment—The right thumb and wrist were immobilised by a plaster of paris slab in the position of rest ' with the wrist somewhat dorsiflexed and the thumb semiflexed The right hand was supported in a sling Intramuscular procaine penicillin 300 000 units was given twice a day for ten days The pain disappeared within twenty four hours and the redness and swelling gradually subsided during the next two weeks On Oct 5 a new plaster slab was applied and the patient was allowed to go home but was asked to attend regularly as an outpatient On Nov 1 she returned to school with her right thumb immobilised by the plaster slab

The plaster was removed on Jan 3, 1950, when radiography showed that the calcification had almost disappeared (fig 2) The range of flexion and extension at the interphalangeal joint of the right thumb was only 10° less than that of the left

On Feb 14 1950, movements of the right thumb were natural and radiography showed that all abnormal calcification had disappeared (fig 3)

On Feb 14, 1951, the right thumb was as mobile and as strong as the left and there had been no pain or disability during the past year X ray examination showed no calcification in the region of the flexor pollicis longus tendon, and the patient was told that she could start playing tennis again next season

DISCUSSION

Tendinitis with calcification, though commonest near the insertion of the supraspinatus above the shoulder, can probably occur in almost any tendon and has been reported in the tendons round the elbow, wrist, hip, knee, and foot (Lapidus 1943) I have not found any record of calcification in the flexor pollicis longus, but Winchester and Mekie (1947) described calcification of the flexor carpi ulnaris near its insertion into the pisiform bone

Their patient was a male clerk, aged 42, and they suggested that repeated trauma, by pressure on the tendon when writing might have been the cause of the trouble On incision " yellow pultaceous gritty material ' was removed from within the tendon.

The most likely cause of the calcification is repeated friction or small strains Single sudden sprains and septic infections, such as tonsillitis, have also been suggested as occasional ætiological factors (Codman 1906)

Treatment in the acute stages is by rest and immobility Massage and movement are harmful, but short-wave therapy may relieve pain Open operation with incision of the tendon and evacuation of the gritty pultaceous material (containing calcium carbonate and calcium phosphate) has been practised with success (Codman 1906, Painter 1907, Emslie 1932, Winchester and Mekie 1947) but seems unnecessary Injection of 2% procaine

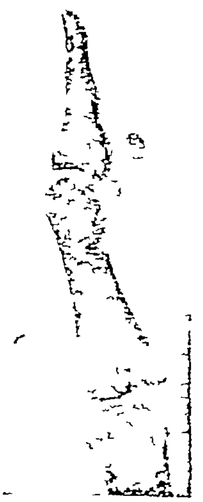

Fig 1

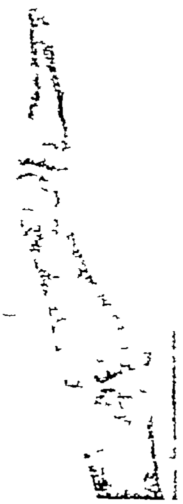

Fig 2

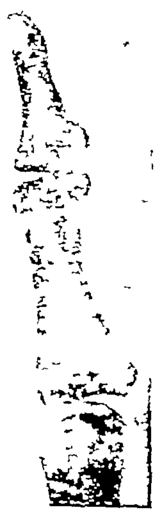

Fig 3

Fig 1—Radiograph Sept. 26 1949 Calcification in terminal portion of right flexor pollicis longus tendon.

Fig 2—Radiograph Dec. 12 1949 Showing that the calcification in the tendon has almost disappeared but there is a small nodule of exuberant bone present at the insertion of the tendon into the base of the distal phalanx.

Fig 3—Radiograph Dec. 19 1950 Calcification in the tendon has disappeared but the excrescence of bone is still present at the insertion of the tendon into the terminal phalanx.

TREATMENT

A case which presents the well defined syndrome as outlined above should, in my opinion, be treated surgically Only the acute case should be treated conservatively either by immobilisation in plaster or by physiotherapy—e g , short wave diathermy and wax baths

In chronic cases the condition is progressive and conservative measures usually fail to relieve the symptoms Even if temporary relief is achieved, cure cannot be effected by these means One of the cases in this series was referred after an unsuccessful period of plaster immobilisation , in 4 other cases conservative measures brought no improvement and operation had to be advised It seems unjustifiable to withhold surgical treatment for a condition which responds to it so readily In 28 of my 30 cases operation was advised, and in 28 it was performed

Operation

The skin over the site of operation is prepared two days before operation and again on the morning of operation After premedication with atropine sulphate gr $^1/_{100}$, a short general anæsthesia is obtained with thiopentone, nitrous oxide, and trichlorethylene This allows the application of an Esmarch bandage, which ensures a bloodless field for the operation As an alternative, regional anæsthesia produced by blocking the brachial plexus with ‘Anethaine’ is very satisfactory This method has been found useful in one or two elderly patients whose general condition precluded general anæsthesia

A small longitudinal incision, 2 in long, is made over the radial styloid process Care should be taken to avoid the terminal branch of the radial nerve as it crosses the tendons on to the dorsal aspect of the forearm about $1^1/_2$ in above the wrist joint, and the digital branch it gives off to supply the skin over the radial side of the thumb These nerves should be defined and suitably retracted The thickened tendon sheath is exposed and incised in the same line This incision should extend into normal sheath both above and below the thickened area, and a strip of the hypertrophied part should be completely excised This ensures that the tendons are no longer constricted, a fact which can readily be demonstrated by passively extending and flexing the thumb The wound is then sutured and a pressure bandage applied

RESULTS

The results of this small operation are uniformly excellent The patient can use his thumb fully without pain, and often notices complete relief immediately after operation

Two of Finkelstein's (1930) patients still complained of pain on pressure over the styloid process ten and eleven months after operation In both of them the tendon sheath was cartilaginous in consistence They were treated in the usual way by the removal of a strip of thickened sheath Finkelstein recommended that in such cases, which are most advanced an even better result could be ensured by the removal of the entire circumference of the sheath This was unnecessary in the present series

In all the 28 cases treated by operation (in 3 the condition was bilateral) the immediate result was excellent, the symptoms being completely relieved Reviewed after periods ranging from a few months to three and a half years only 2 cases show results not altogether satisfactory

A girl, aged 14, still complains of weakness and pain in both wrists, although she only had slight thickening of the tendon sheaths at operation

A woman, aged 53, still complains of numbness and vague pains in both wrists She is neurasthenic, and her symptoms are consequently difficult to assess

The 2 patients not treated by operation had mild symptoms These were temporarily relieved by physiotherapy but the pain comes back from time to time

DISCUSSION

Stenosing tendovaginitis at the radial styloid process is somewhat allied to trigger finger, in which a thickening develops, in the sheaths of the flexor tendons to the fingers, over the metacarpal heads in the palm of the hand The thickened sheath constricts the enclosed tendons and impedes their action Immediate relief is afforded by division of this thickened sheath

I have known a similar thickening to develop in the sheath of the flexor carpi radialis muscle at the wrist

A housewife, aged 52, had had for six months a painful swelling, over the anterior surface of the wrist, which was getting worse There was no history of injury She had had an exactly similar swelling in the left wrist eleven years previously This had been explored, but it was said that nothing abnormal was found

On examination a very tender swelling was found about the size of a finger tip, over the tubercle of the scaphoid Radiography was negative Immobilisation of the wrist in plaster having procured no relief, operation was undertaken The sheath of the flexor carpi radialis tendon was found to be much thickened and the tendon to be constricted The sheath was incised and part of the thickened area excised The flexor retinaculum was not thickened, and the median nerve was not compressed The patient made a good recovery

Histological examination of the thickened sheath revealed the presence of plasma cells and an appearance such as would result from a long standing inflammation

These three conditions—stenosing tendovaginitis at the radial styloid process, trigger finger, and thickening of the flexor carpi radialis tendon sheath—are manifestations of the same pathological process—namely, thickening and stenosis of the tendon sheaths, due to fibrosis, possibly the result of a low grade inflammation Though the precise ætiology is debatable, the consensus of opinion is that the condition is largely due to repeated trauma I do not think that stenosing tendovaginitis of the flexor carpi radialis (as described above) has previously been recorded, but Finkelstein (1930) observed similar changes in the sheaths of the extensor carpi ulnaris, flexor pollicis longus, and the extensor pollicis longus tendons

The syndrome of median nerve compression at the wrist described by Brain et al (1947) is a separate condition in which the median nerve is compressed by the flexor retinaculum (annular ligament) at the wrist as it lies in the carpal tunnel Various degrees of median nerve palsy arise, and the condition is relieved by surgical division of the flexor retinaculum

In the case described above in which tendovaginitis affected the flexor carpi radialis tendon, the flexor retinaculum was not thickened and the median nerve showed no evidence of compression, being normal in appearance Median nerve compression at the wrist would, because of similar subjective symptoms, enter into the differential diagnosis

SUMMARY

Stenosing tendovaginitis at the radial styloid process is usually a chronic condition, found mostly in women employed in housework

The patient very often gives a history of injury

The tendon sheaths are locally thickened and compress the tendons of the abductor pollicis longus and extensor pollicis brevis muscles

Conservative treatment should be applied only to the rare acute case following trauma

The established case should be treated by incision of the tendon sheath and excision of that part of it which is thickened

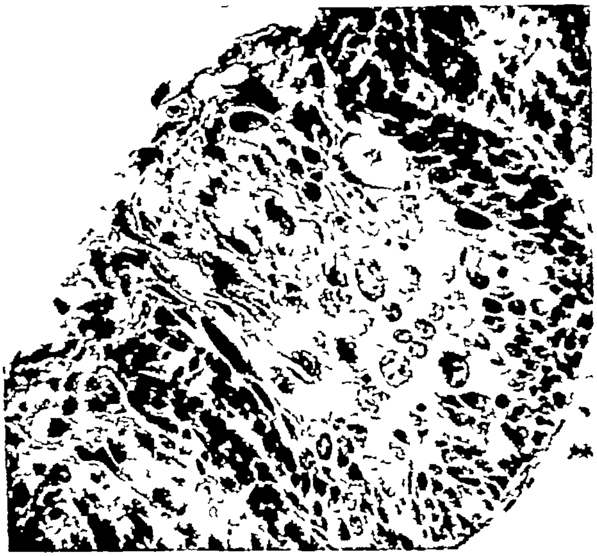

Fig 4—Malignant squamous epithelium (× 270)

Traut (1941), or in surface biopsies from the cervix, as suggested by Ayre (1947), is leading to the discovery of a new crop of early cancers, even by those with no special intensive training, though naturally a lower incidence of errors follows from training and long experience. The smear or surface biopsy could be arranged for every woman at a gynæcological clinic, whatever her complaint, and should probably be done in every parous woman over 30 who is admitted to a gynæcological ward for any reason. Many hospitals in the U.S.A. do not now undertake cauterisation of the cervix until malignancy has been excluded so far as possible by smear or biopsy. But the interpretation of these smears can be both difficult and time consuming, and is so far only being undertaken in a few of our larger teaching centres.

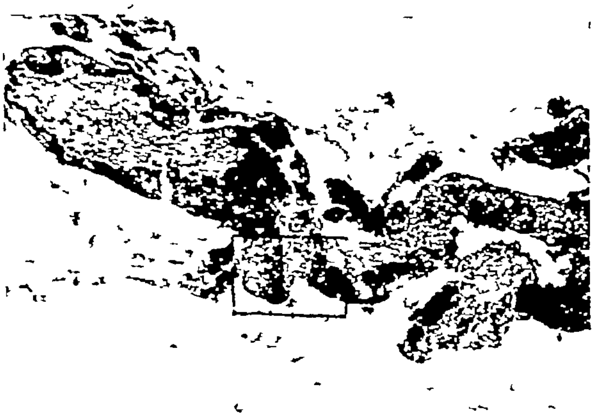

Fig 5—Cervical curetting showing malignant epithelium (low power)

When a "positive" (malignant) smear is found yet to the clinician the cervix presents no special site demanding biopsy, Schiller's iodine test is the only simple intermediate method between a surface smear and a "ring" biopsy of the entire junctional epithelium, as advocated by Ayre (1948), for finding the possible malignant area. Wespi (1950) combines Schiller's test and inspection of the cervix with Hinselmann's colposcope, and believes he can discover the majority of early growths; but again this is not easy, nor have such few colposcopes as there may be in this country led to results making the learning and practice of their use obligatory. A "ring" biopsy is not always easy to obtain properly, and Novak (1949) prefers a sharp spoon with which he lifts off the surface junctional epithelium. This is still most efficiently obtained under anæsthesia with a volsellum on the cervix, though it can be done without, and the epithelial strips resulting are essentially more accurately and more easily interpreted than are single cells in a smear. It is really a simple method of searching for the early cancer in all cases admitted for gynæcological operation, and is intermediate in thoroughness between the smear and the ring biopsy, obviating the difficult interpretation of the one and the trauma of the other, to which none of us would subject all our patients routinely. The curved spoon curette (fig 1) is merely a modification of the straight spoon curette (still best used for the endocervix). A special sharp cutting edge is applied, and the curette is angled so that it may be used against the junctional epithelium by rotating the handle in the axis of the vagina. Figs 2 and 3 show a strip of squamous epithelium so obtained, the specimen being fixed and mounted in paraffin as usual. A strip of

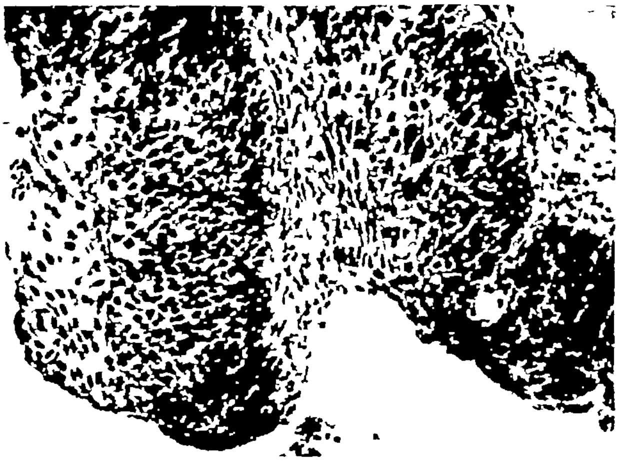

Fig 6—High-power view of area marked in fig 5

malignant epithelium is shown in fig 4. Figs 5 and 6 show malignant epithelium found by curetting the cervix. The discovery of this epithelium led to a "ring" biopsy, which in turn led to the discovery of a superficial early but probably invasive, epidermoid cancer (figs 7 and 8).

It is more difficult to draw off strips of epithelium from some cervices than from others, but it is always possible. Should suspicion have been raised by examination of a smear previously, the endocervix also should always be inspected after dilatation and the straight spoon curette used to obtain endocervical scrapings—a step too easily omitted. With such fragile strips as the curved scoop obtains it is essential that they should all

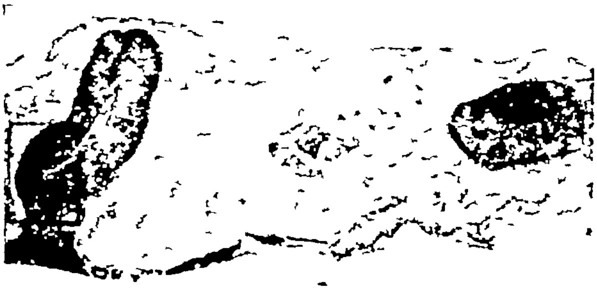

Fig 7—Ring biopsy specimen taken from cervix after the findings shown in figs. 5 and 6. A superficial early but probably invasive epidermoid cancer

into the tendon may relieve pain if this is severe Injection of local anæsthetic solution and saline solution followed by aspiration has been used with success, and Sandstrom (1938) advised local rest combined with X ray therapy

I consider that complete rest, which entails plaster immobilisation in the acute stages, is all that is usually necessary

I am indebted to Dr G R Sunley for referring the patient to me and for his help in her treatment, and to Prof A S Johnstone for his kind advice

CURETTAGE IN THE DIAGNOSIS OF CERVICAL CANCER

A MODIFIED SPOON CURETTE

A F ANDERSON
M B Edin , F R C S E , M R C O G
LECTURER IN OBSTETRICS AND GYNÆCOLOGY, UNIVERSITY OF EDINBURGH

THE need for reviewing the steps usually taken to diagnose cancer of the cervix comes from the realisation that this lesion commonly arises at the average age of 37, very much earlier than we have been accustomed to suppose The average stage I cancer ("established," invasive) is already an old cancer, presenting with well known symptoms and signs By this time there is usually some point on the cervix suggesting the site from which a biopsy should be taken, or else it is to be found in the endocervical canal These cases have already a 20% probability of lymph node involvement, and their average age incidence is 45–50 They are cases which are clinically suspected

But what of those cases not clinically suspected? These are of two types (1) those showing very early invasion of the connective tissue, and (2) those showing no invasion, in which the growth is confined to the superficial epithelial layer or its extension into the lumen of a cervical gland These two stages have an average age incidence of 42 in the first type (Auerbach and Pund 1945), and 37 in the second, and still younger, type (Auerbach and Pund 1945, TeLinde and Galvin 1944)

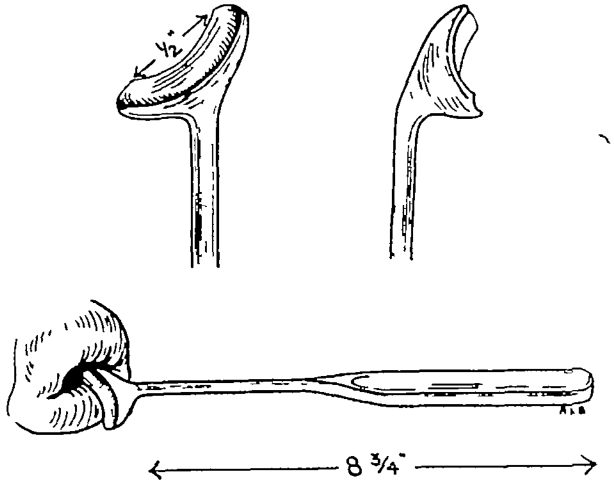

Fig 1—Spoon curette modified for routine use on junctional epithelium of cervix

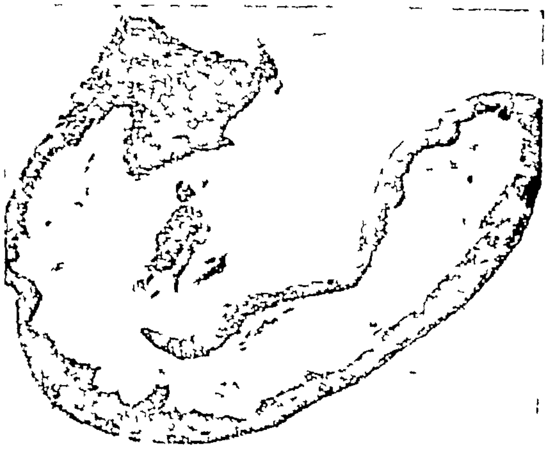

Fig 2—Strip of non-cancerous epithelium obtained with spoon curette (× 20)

Women with these really early cancers may have symptoms, but they are not symptoms suggesting cancer, and the appearance of the cervix with an intact epithelium does not suggest cancer A cervix with a "suspicious area" on it visible to the naked eye most commonly turns out to be benign ("erosion," ulceration) or quite malignant, with invasion already established, and very seldom a young superficial or pre invasive type of cancer

Foote and Stewart's (1948) excellent "mapping" of the extent of 27 such pre invasive cancers shows how the usual single biopsy fragment may only discover half these cases, and how biopsy from both anterior and posterior cervical lips may only discover three quarters, and it confirms Schiller's finding that these early cancers most commonly begin at the junction of the squamous and the columnar epithelium at the external os That this early cancerous change in the epithelium necessarily becomes an invasive cancer is as nearly proved as is possible by the number of such cases not radically treated owing to misinterpretation of the original picture and eventually developing an invasive cancer TeLinde (1949) mentions 18–20 such cases, I have since added 3 more in this country (Anderson 1950), and Younge et al (1949) report a case deliberately left untreated in which monthly biopsies showed invasive cancer eleven months later

The increasing practice of searching for malignant cells in vaginal smears, as suggested by Papanicolaou and

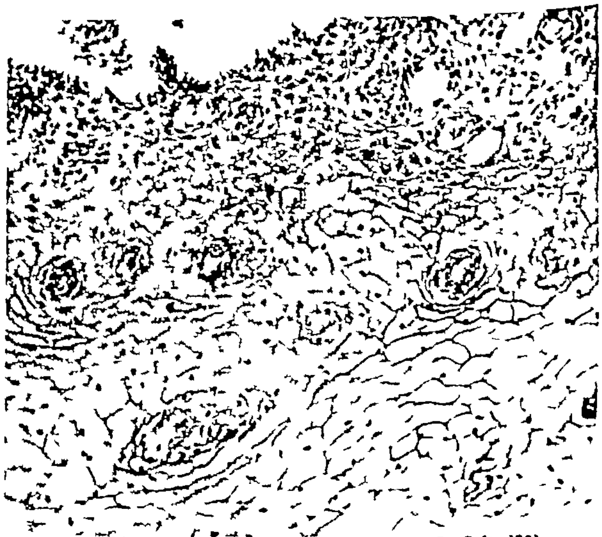

Fig 3—Higher-power view of same strip as fig 2 (× 120)

lesion of the upper lobe of the right lung, resembling a patchy pneumonic consolidation, with no cavity formation. This lesion had partially resolved by May 18

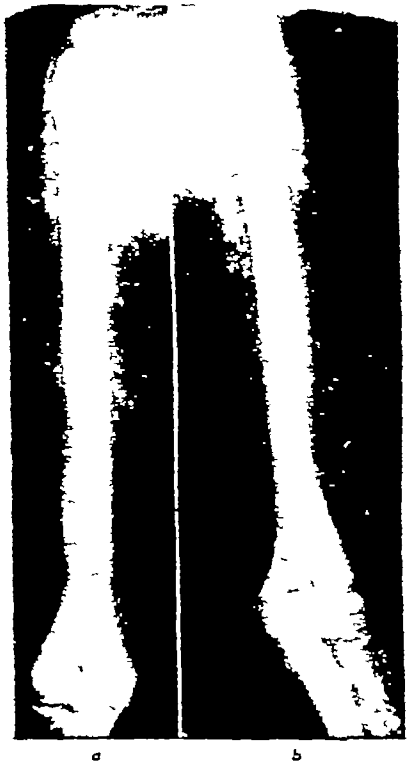
A week before admission he began to feel throbbing intermittent pain in his right leg with much tenderness. The pain caused him to limp and was not worse at night There were no symptoms referable to any other limb In 1938 he had similar pain and had been in hospital for a week.

On admission his appetite was good and his bowels regular Examination showed a cataract in the left eye diminished air-entry at right lung base a maximal cardiac impulse in the fourth space in the midclavicular line, and a small umbilical hernia. No abnormality was found in the central nervous system.

Two inches above the ankle joint the right leg was slightly swollen, hot and tender Slight pitting could be elicited. Shotty glands were present in both groins The left leg was apparently normal The urine contained urobilin (+ + +) and bilirubin (+ +) but was otherwise normal. A white-cell count showed 17 000 cells per c.mm. Hb was 10 g per 100 ml.

Initial Treatment—The patient was given penicillin 100 000 units three-hourly

Radiography of the chest on June 9 showed almost clear lungs with minimal shadowing in the right infraclavicular region, apparently the residuum of the patchy area of pneumonitis originally demonstrated on May 9 1949 Radiography of the right leg showed extensive erosion of the shaft of the tibia (fig 1a) involving the cortex on the anterior aspect and severest in the middle third In the upper third there was some erosion on the posterior aspect, with periosteal reaction. The swelling on the anterior aspect of the tibia was distal to the affected cortex. There was no change in the tibia near the joint surfaces There were no symptoms or signs referable to the left leg (fig 1b), which showed very similar erosion, chiefly of the middle third of the tibia on the anterior aspect. There was however some involvement of the medulla.



a b

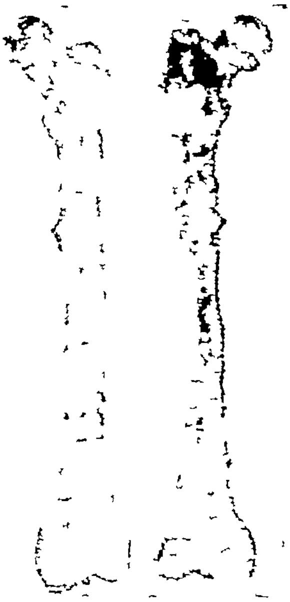
Fig 2—Osteoperiosteal reaction limited to mid-shaft of humerus a right arm b left arm.

Because the appearance and distribution of the erosion was similar to that seen recently in a case from a neighbouring hospital it was suggested by one of us (M. F) that the infective organism in this case of osteomyelitis might be the Friedländer bacillus

Laboratory Investigations—An Ide test was negative The serum albumin 3 3 g and serum globulin 3 7 g per 100 ml. Thymol turbidity, 3 5 units thymol flocculation negative (—), Takata Ara test positive (+ + +) Alkaline phosphatase (King Armstrong) 15 5 units Icteric index 8, and bilirubin test direct positive 0·5 mg per 100 ml. Blood-culture negative for *S typhi* A specimen of cerebrospinal fluid 3 lymphocytes per c.mm., total protein 60 mg., chloride 0·660 mg and sugar 80 mg, per 100 ml Wassermann reaction negative Agglutinations for typhoid paratyphoid *Brucella melitensis* and *Br abortus* negative

Aspiration—On June 11 1949 the abscess of the right leg (lower third anteriorly) was aspirated and 5 ml. of brownish bloodstained pus was withdrawn. Microscopy of the pus showed pus cells and gram negative capsulated bacilli. Culture yielded a pure growth of an organism culturally and biochemically resembling Friedländer s bacillus. The bacterium was sensitive to streptomycin in a concentration of 100 μg per ml. but insensitive to penicillin 100 units per ml and to sulphadiazine, sulphapyridine, and sulphathiazole in a concentration of 1 5000 Aspiration was repeated on June 14, 1949 The pus contained pus cells and gram-negative bacilli Cultivation yielded an abundant growth of Friedländer s bacillus On June 17 a further specimen gave a similar result, and next day examination of pus from the thigh showed numerous pus cells and gram negative bacilli.

Blood examination on June 14 showed Hb 10 g per 100 ml., colour index 0 96, red cells 3 370 000 per c.mm., leucocytes 16 300 per c.mm. (neutrophils 87 0%, mononuclears 5·5% lymphocytes 7 5%, eosinophils 0) On June 23, 1949 the serum agglutinated Friedländer s bacillus to a titre of 1 25 only Culture yielded an abundant growth of Friedländer s bacillus and scanty coliform bacilli insensitive to Aureomycin.



a b

Fig 4—Extensive pitting and periosteal reaction of entire shaft of left femur a anterior view b posterior view

Other Bones—More detailed examination of the arms revealed deep-lying induration over the lower third of the humerus on both sides, and radiography showed osteomyelitis in both humeri (fig 2) more extensive on the right than on the left, involving the cortex more than the medulla, and with marked periosteal proliferation. As in the tibiæ the distal and proximal ends of the bones were not involved. The left ulna showed some erosion in the cortex on the posterior aspect of the middle third. The bones of the forearms were otherwise uninvolved. In the left femur (fig 3) there was extensive erosion of the cortex and medulla, most marked on the posterior aspect, and with profuse periosteal proliferation. There was a similar lesion in the middle third of the right femur affecting chiefly the cortex on the lateral aspect The whole of the rest of the skeleton was radiographed with negative results All these bone lesions, except that in the right tibia were neither painful nor tender

Fig 3—Profuse periosteal proliferation in shaft area of left femur

Progress—On June 20 1949, the left leg and thigh became swollen The left calf was tender and Homans s sign was positive. There was an effusion in the left knee joint The whole leg became extremely painful Acute thrombophlebitis was diagnosed. Two days later the thigh was somewhat indurated, and underlying infection was suspected.

Aspiration and Operation—Subsequently 60 ml. of thick brown pus was aspirated Open drainage was advised but the patient refused operation. Aspiration followed by instillation of penicillin was persevered with until July 19 1949 when the patient consented to operation. By this time the thigh was grossly swollen and the knee joint infected.

be sent for examination, and *immediately* floated off the curette by immersion in fixative solution, because the drying, and possible loss, which may take place if they are laid on a gauze swab may be so considerable as to confuse the picture and entirely nullify the trouble taken by clinician, technician, and pathologist The endocervical fragments, if any, should always be dropped into a separate container of fixative

No doubt, even if this procedure were a regular practice, some early cancers might still escape discovery, but it is probably a much more fruitful "routine" step in the examination of a gynæcological patient than are many curettages now being done for no very obvious reason other than that the patient is anæsthetised, as pointed out by Bowes (1949), and certainly it should make us more "cervix conscious" The reward of the discovery of these very young and early cancers should be a survival rate approaching 100%

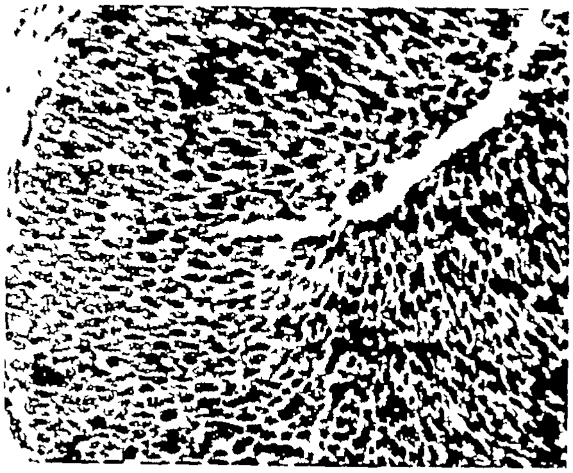


Fig 8—High power view of epidermoid cancer

Some workers still incline towards the view that the finding of more stage I cancers holds out the greatest promise of reducing the mortality of this most common and distressing tumour, but the onus cannot be entirely placed on the patient, and the very accessibility of the cervix, coupled with the absence of symptoms in the earliest type of case, cannot but shift more of the onus on to the gynæcologists

The modified spoon curette was made by the Medical Supply Association Ltd

' There are about 200 medical officers of health employed by Local Health Authorities, and though figures are not available probably about 2000 doctors are employed altogether in the preventive services Is it right that there should be one doctor in the hospital and specialist services for every 13 or 14 patients and one general practitioner for 2200 panel patients? Is one doctor per 20,000 of the population the correct proportion of the country's medical man power to be allocated to the prevention of disease? The time has obviously come when some authoritative body should investigate the relative claims on the available pool of man power for the medical services, indeed, for the utilisation of all the professional services, and its primary task should be to find out what proportions are desirable for each branch of service —Dr HUGH PAUL *Med Offr*, May 19, 1951, p 201

OSTEOMYELITIS DUE TO FRIEDLANDER'S BACILLUS

D A MUSKAT
Ch M Rand
ASSISTANT SURGEON

M FINDLAY
M R C S, D.R Edin.
SENIOR RADIOLOGIST

CORONATION HOSPITAL, JOHANNESBURG

MULTIPLE metastatic osteomyelitis, excluding that due to *Treponema pallidum*, is uncommon The organisms usually responsible are staphylococci, streptococci, pneumococci, *Salmonella typhi*, or *Mycobacterium tuberculosis* Until recently Friedlander's bacillus has not been reported as causing osteomyelitis, though it had been found in almost all the organs of the body (Wilson and Miles 1946, Browning and Mackie 1949) Two cases, however, have occurred in Bantu patients in another hospital in Johannesburg (Comins et al 1950), and a third is reported here The clinical findings were peculiar and the radiological features so characteristic that, while awaiting the report on the culture of pus aspirated from the abscess, one of us (M F) was able to suggest the diagnosis

CASE RECORD

A Bantu male, aged 41, a printer's assistant, was admitted on June 8, 1949, with pyrexia He complained of tightness in the chest and hiccup, and for a week his right ankle had been painful

History—The "tightness in the chest" started about March 21, he had no pain in the chest and did not cough. On April 23 he was admitted to another hospital, whose notes stated that he looked very ill, and had herpes labialis acute pharyngitis, and generalised abdominal tenderness. He was found to have severe normochromic anæmia and was given a transfusion of 500 ml of blood He improved, but two weeks later his condition necessitated a further transfusion of 500 ml His temperature ranged between 99° and 103°F Large doses of penicillin (for a month) and streptomycin (for two weeks) caused no improvement Thirteen specimens of urine and nine of fæces were negative for *S typhi* Blood culture and Widal and Vi tests were negative, and no *M tuberculosis* were found in the sputum There was a "pronounced leucocytosis" Radiography on May 9 showed a

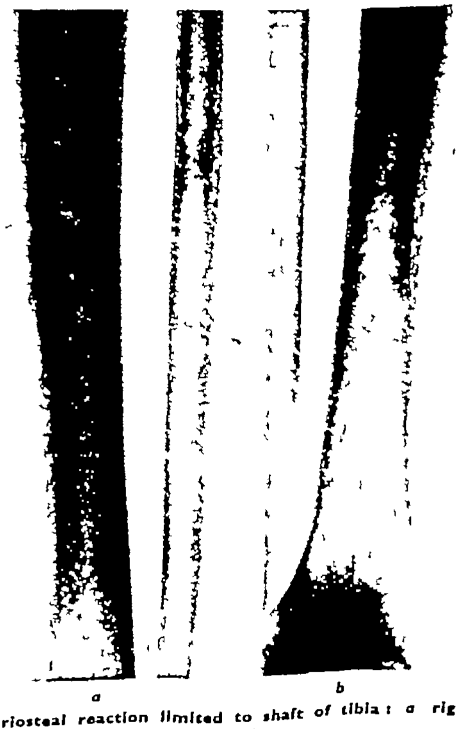

Fig 1—Periosteal reaction limited to shaft of tibia: *a* right leg *b* left leg

use Depression of the cough reflex is, in itself, much less important

If morphine has already been given, and the onset of ill effects noticed in the form of shallow and infrequent breathing, increased cyanosis, and coma, nikethamide 5–10 ml. should be given slowly intravenously, and oxygen administered

The essence of the danger seems to lie in the failure to differentiate between the useless dyspnœa of other forms of heart failure and the compensatory hyperpnœa of cor pulmonale In the former morphine is life saving, in the latter lethal.

SUMMARY

Morphine is deadly in heart failure secondary to chronic lung disease

Six patients are described who illustrated this

Nikethamide, given intravenously, is valuable in rescuing the patient if the ill effects are noticed in time

I am indebted to Dr A H Holmes and Dr N Kletts for their kind permission to report these cases

STREPTOMYCES FERMENTATION DERIVATIVES IN ACUTE LEUKÆMIA

Robert D Barnard
M D
OF LAURELTON, LONG ISLAND, NEW YORK STATE

Early in 1949 I began giving acute leukæmic patients a crude *Streptomyces griseus* fermentation by product, sold as a hog and poultry feed supplement It had been noticed that in cases of amyotrophic lateral sclerosis this product created a ravenous appetite and a strongly positive nitrogen balance—effects beyond those obtained with relatively pure B_{12} preparations (Barnard 1950) Unexpectedly, within 24–72 hours most of the acute leukæmia patients who were given the streptomyces residue went into what was apparently a remissive phase of the disease with sudden abatement of fever, cessation of bleeding, and a remarkable clinical improvement Unfortunately, however, in these cases there was seldom any comparable improvement in the blood picture, though in a few cases the remission was hæmatological as well as clinical (Barnard and Fox 1950, Barnard and Appel 1950) Later in 1949, when a new batch of the product was used, the results became entirely negative, though its vitamin B_{12} content was similar, and a chance observation led to the discovery that a residual antibiotic, not the B_{12}, was responsible for the remission in acute leukæmia, and also for improvement in other atopic diseases and in animal growth (Barnard 1951a) The conclusion was finally reached that any of the streptomyces derived antibiotics ('Terramycin ' 'Aureomycin,' chloramphenicol, streptomycin), given in such a way as to suppress the usual coli aerogenes intestinal flora, may induce remission of acute leukæmia and that this remission will be maintained until (usually in a few days or weeks) antibiotic-resistant strains repopulate the intestinal tract, after which relapse is rapid Nevertheless an occasional patient did not show this relapse, and it was found that those who happened to be taking large quantities of milk had developed and maintained a lactobacillus type of intestinal flora which probably suppressed the coliforms

To produce convincing statistics is difficult because so many other factors seem inseparable from the life and death of the acute leukæmic once he has been so diagnosed Of the 50 patients who have now purposely * been treated with antibiotic containing streptomyces derived materials, many were transfused occasionally or repeatedly; and though sometimes these transfusions were probably not harmful † they often appear at such a time in the case history as to prevent rigorous appraisal of the rôle of the antibiotic My statement that hæmatological improvement was seldom apparent should be qualified by saying that almost always there was deceleration or cessation of the usually progressive anæmia the erythrocyte count seemed to stabilise itself at a level which was lower than normal but which apparently was physiologically adequate, for many patients were able to return to school or to work This small blessing did not satisfy some of the attending physicians, or some member of the patient's family—after all, the blood picture was " bad "—and the bulk of the series made exitus via the " antifol " route, after discontinuance of maintenance antibiotic therapy or after what must be regarded as a purely elective blood transfusion Some died from acute congestive heart failure imposed by the (then) unappreciated salt and water retentive effects of adrenocorticotherapy , though I must add that, strangely enough, administration of the streptomyces derived antibiotics, or the change in intestinal flora this may entail, has likewise produced profound adrenocorticomimetic effects which were not always in the interests of the patient Diuretic doses of ammonium chloride are now given to most patients receiving sustained oral antibiotic therapy, but the corticomimetic effects are still so conspicuous that we cannot expect to evolve a satisfactory supportive régime in acute leukæmia until we have considerably more clinical experience Accordingly—and because there have only been 6 one year survivals among 50 patients—I shall confine myself here to describing 3 cases which illustrate (1) the rôle of the streptomyces fermentation product in the induction of remission, (2) the probable identity of the active factor, and (3) its possible mode of action

ILLUSTRATIVE CASES

Case 1 —A girl, aged 17, developed a viral " pneumonia in November 1949, and was treated at home throughout her illness When she did not respond to penicillin (fig 1), and when gum bleeding became pronounced and the spleen was found to be palpable, the blood was examined on Dec, 13 The peripheral smear itself was diagnostic of an acute myeloblastic leukæmia, there being a complete granulocytic hiatus between " blast " and mature forms , but marrow aspiration was also performed (Dec 22) and revealed over 80% of nucleated forms to be undifferentiated and while megakaryocytes were absent On Dec 25 40 g of *Streptomyces griseus* residue (now known to have a B_{12} equivalence, per gramme of 6 µg on the basis of L *leichmanii* assay and 220 " units ' of streptomycin equivalence in terms of *Bacterium coli* suppression) was begun in four divided daily doses, the material being emulsified in milk with linseed oil and Tween 80 At the end of 24 hours the patient, though still febrile, was so much better that consent was obtained to discontinue the parenteral penicillin. Temperature was normal within 72 hours of commencing the residue ingestion and the patient left her bed A strong revulsion developed against the residue mixture at about the end of the second week of its exhibition, and attempts to force it were met with retching and vomiting Relapse was manifest

---

* Many acute leukæmic patients are now of course receiving aureomycin terramycin or chloramphenicol as a supportive measure for the control of the infective component supposedly connoted by fever The possibility that chloramphenicol may be the cause of some purported antifol remissions has been noted (see McNeil 1950) The patients in my series ordinarily received an antibiotic dosage which was considerably less than that used for the treatment of infections and was actually of the same order of magnitude as that found to induce optimal growth in hogs

† In many instances I believe they actually killed the patient as when blocking type antibodies were present (Barnard 1951b)

Under thiopentone anæsthesia 4 pints of pus was removed Three days later the leg had subsided greatly, but the patient's condition generally did not seem to improve commensurately Two transfusions of 500 ml of blood were given On July 25 the right thigh became swollen. On July 28, 400 ml of pus was evacuated through a deep incision. The patient's condition deteriorated, and he died on July 30, 1949, apparently from profound toxæmia

Treatment had been mainly supportive A high vitamin, high protein, and high carbohydrate diet was given A course of penicillin and sulphadiazine was given despite the insensibility of the causal organism Streptomycin was given continuously in doses of 2 g a day For a fortnight before death the dose was increased to 3 g a day (there being no signs of toxicity) Aureomycin was given in the last week without benefit

Necropsy Findings —There was evidence of general toxæmia, particularly affecting the heart and spleen The liver was soft and showed fatty degeneration In the right lobe of the liver was a small necrotic abscess filled with yellowish green pus The left femur was bathed in pus, and the surrounding muscles were necrotic The left femur was irregular, with some periosteal new bone formation posteriorly (fig 4) The findings on the right side were similar but not so pronounced Nothing abnormal was found in the lungs

COMMENTS

This case presents interesting and unusual features Although throughout the clinical course there was no cough, expectoration, or clinical evidence of a lung lesion, the initial radiological finding did show a lesion

The condition was characterised by high remittent pyrexia, becoming intermittent, severe toxæmia, moderately high persistent leucocytosis, and osteomyelitis of almost all the long bones, either simultaneously or in rapid succession

Even with definite radiological changes the clinical findings of pain, tenderness, and swelling (before the onset of gross suppuration) were slight

Friedlander's bacillus produces abundant brown blood stained pus, with a musty, but not foul, odour, and can be isolated in pure culture It is apparently, in vitro, sensitive to streptomycin, but in the present case intensive streptomycin therapy had no effect

Pathologically the main changes were an extensive periosteomyelitis, with a definite tendency to form new bone No sequestra, cloacæ, or sinuses developed

LETHAL EFFECT OF MORPHINE IN CHRONIC COR PULMONALE

N J Roussak

M B , B Sc Manc , M R C P

MEDICAL REGISTRAR, MANCHESTER ROYAL INFIRMARY

No physician would disagree with Sydenham's oft quoted eulogy of opium, and yet this drug, no less than newer potent therapeutic aids, may be a double edged weapon It is the purpose of this communication to re emphasise the extreme danger attending the use of opium in heart disease of pulmonary origin

Five patients whose deaths were precipitated by the drug are described, and one in whom the fatal result was averted

CASE RECORDS

Case 1 —A man, aged 58, was admitted to hospital with bronchitis and emphysema and recent superadded infection. He showed cyanosis, dependent œdema, and venous congestion, and the liver was enlarged Given oxygen, penicillin, and morphine gr $^{1}/_{4}$, he sank into coma with shallow respirations and died in a few hours

Case 2 —An emphysematous man, aged 62, had a chest expansion of only $^{1}/_{2}$ in Moderate cyanosis, œdema of the legs, and an enlarged liver were present He was comfortable, though slightly dyspnœic, in bed 'Nepenthe' 30 minims resulted in diminished amplitude of respiration , coma and death followed

Case 3 —After operation for perforated ulcer a man, aged 64, with bronchiectasis found his exercise tolerance much reduced, and signs of right sided heart failure developed This responded to treatment, and the sputum diminished and became less offensive One night the patient was given morphine gr $^{1}/_{6}$ for ulcer pain , sleep merged into coma, and he died.

Case 4 —A man, aged 28, was admitted with bronchiectasis and congestive heart-failure Rapid and unexpected deterioration followed the administration of morphine gr $^{1}/_{4}$, cyanosis deepened, and the patient died shortly afterwards in coma.

Case 5 —A man, aged 30, with bronchiectasis and right sided heart-failure was treated in hospital on several occasions. Ultimately he was given nepenthe 30 minims , respiratory movements weakened, cyanosis increased, and he lapsed into coma Oxygen was of no avail, and he died

Case 6 —A grossly obese man, aged 42, had unexplained right-sided heart-failure which responded well to digitalis and diuretics Emphysema and bronchitis, not at first considered very severe, were shown to be the cause of the failure when, instead of his nightly barbiturate, he was unfortunately given nepenthe 30 minims Seven hours later he was found in deep coma, almost apnœic, and heavily cyanosed Oxygen was given, and nikethamide 10 ml. administered slowly intravenously Respiration increased in depth and his colour improved while the needle was still in the vein, and within five minutes he was conscious, although rather dyspnœic This patient is still alive two years later

These patients had congestive heart failure secondary to chronic lung disease, and some were already showing gratifying signs of improvement The condition of each deteriorated dramatically after morphine or nepenthe had been given

DISCUSSION

Apart from the statement that morphine *should not* be given in bronchial asthma or in the presence *of copious* bronchial secretions, " because of depression *of the* cough reflex," little mention is made in textbooks or the literature of the danger of morphine in cor pulmonale

Discussing the treatment of congestive heart failure, East and Bain (1948) write " Ventilation may well be diminished without harm if the reflexes provoking it are quieted A less than normal oxygen tension can quite well be tolerated " " Morphia is dangerous in heart failure secondary to kyphoscoliosis, also when the failure is complicated by sepsis Old people are sometimes very sensitive to morphia Otherwise its use is free from all risk " The danger in kyphoscoliosis (Daley 1945) is due to the associated reduced vital capacity Price (1941) advises that small doses of morphine should first be given in heart failure, and the effects noted, but no special mention is made of cor pulmonale White (1945) does not mention the matter, but Levine (1945) and Wood (1950) warn against the use of morphine in cor pulmonale Friedberg (1950) writes " Morphia causes serious respiratory depression and occasional fatalities in patients with pulmonary failure, and is therefore contra indicated "

In the presence of greatly diminished vital capacity sufficient oxygenation of the blood may only be achieved by maximal respiratory effort (hyperpnœa) Such hyperpnœa is produced by stimulation of the respiratory centre by the decreased oxygen tension of the blood, the arterial oxygen saturation being *often* 70–35% in emphysema (McMichael 1947) Afferent vagal impulses from the lungs, and impulses from the carotid bodies, also play a part, but it is *thought* that the centre becomes insensitive to the continuously raised carbon dioxide tension (Donald and Christie 1949)

It is essential that the respiratory centre remain responsive to such stimuli, and it is the depressing effect of morphine on it that causes the deaths following its frequently, aureomycin does so occasionally, and oral penicillin appears to have done so in 4 instances. The efficacy of these antibiotics in this connection is strikingly parallel with their efficacy in promoting growth in poultry and hogs, and the underlying mechanisms may be the same. My present working hypothesis is that the proteosæmia ("peptonæmia") repeatedly demonstrated in acute leukæmia (Erben 1900) arises from a predominantly proteolytic flora in an intestinal tract of increased permeability, and that this proteosæmia is responsible for the depression of blood cholinesterase, whose level is lower in acute leukæmia than in any other condition (Barnard et al. 1946). The rôle of the blood-cholinesterase in the general regulation of cellular permeability has only recently become an open topic (Holland and Greig 1950), its function in regulating hæmopoiesis has been subject of surmise (Barnard 1948). On this hypothesis, the proper antibiotic for suppression of proteolytic species may vary in different subjects.

Case 3.—A school teacher, aged 69, was admitted to hospital on May 12, 1950, with developed stranguary, abdominal pain, and hæmaturia. A diagnosis of acute prostatism led to plans for transurethral resection, but a severe anæmia was found, and operation was postponed until the patient could be "built-up" with transfusions. What was overlooked in the routine blood count was a leucocyte figure of 8000, which the technician stated were "all lymphocytes," and a note that platelets were sparse. Aureomycin administration was begun on admission. Transfusions before operation had little effect. Examination of the original blood film and of a routine blood-count record made in November, 1949, when the patient enrolled in a local health insurance plan, led to the tentative diagnosis of acute lymphoblastic leukæmia. During the first four weeks in the hospital the leucocyte count fluctuated from 8000 to 80,000 (fig. 2) but the percentage of 'blast' forms among these also varied with the total leucocyte-count, the absolute numbers of 'blasts,' like the small numbers of granulocytes, remaining remarkably constant.

Transurethral resection was performed during the second week in hospital, and bleeding from this site continued. A double transfusion five days after operation almost killed the patient. The course completely altered on the substitution of terramycin and chloramphenicol for the aureomycin, all bleeding and fever abating. The patient himself noticed that the change over had produced an almost odourless stool, and this state of affairs has continued with a predominantly gram-positive intestinal flora. When last heard from, about eight months after the apparent remission began, the patient was in the best of health and at work.

In this case terramycin apparently eliminated an aureomycin-resistant strain of *Bacterium aerogenes*. Relapse may have been prevented by a liberal intake of milk which maintained a predominance of lactobacilli antagonistic to the coli-aerogenes group. This case also illustrates how cessation of bleeding may indicate the beginning of a remission. The effect seems not entirely due to the anti-heparin effect of terramycin (Barnard 1951b), since aureomycin likewise neutralises heparin (Barnard 1951b).

The long-term 'hæmatinic effect' of continued small doses of antibiotic is well shown by this patient, whose erythrocyte count continued to climb without the necessity of transfusion. This effect, identical with that observed when streptomyces fermentation derivative was given for the usually refractive anæmias of glomerulonephritis, hypersplenism, and protracted radiotherapy, is perhaps the most promising feature of the use of this product in acute leukæmia. Another is its tendency to abrogate "allergic" manifestations, a history of which is so common among leukæmic patients and members of their families.

SUMMARY

Food supplements obtained by fermentation with *Streptomyces griseus* have been given by mouth to patients with acute leukæmia. In some cases the clinical condition has greatly improved, but the blood picture has not shown corresponding changes.

Though the products used are rich in vitamin B_{12} their effect in leukæmia is more probably related to their content of antibiotic. Streptomyces derived antibiotics alter the intestinal flora, suppressing the coli-aerogenes organisms, and the clinical remissions seem to last until antibiotic-resistant strains emerge to repopulate the gut. This event was apparently postponed in patients whose large intake of milk promoted the growth of lactobacilli.

Untoward effects on salt and water balance have been observed in some cases treated with streptomyces fermentation products, and more experience will be needed before any satisfactory régime for their use can be evolved.

ADDENDUM

Since this report was prepared examples of remission in the leucoblastoses, including Hodgkin's reticulioma and disseminated myeloma, apparently due to small doses of streptomyces-derived antibiotics, have continued to accumulate, and the concomitance of an odourless stool and remission remains striking. That these effects have not always emerged with regular large doses of antibiotic may be explained by Kersey's (1951) finding that the streptomyces derived antibiotics, thought not ordinarily suppressing lactobacilli, develop this action at a critical level which depends partly on the amount of B_{12} present. Kersey's data indicate that the lactobacillus would probably survive in the intestine at a terramycin concentration which would result from administration of small doses, but that it would not survive with ordinary doses. This probability is being borne out by studies on fæcal flora.

I wish to acknowledge my indebtedness to Chas. Pfizer and Company, Brooklyn, for providing generous quantities of *Streptomyces griseus* residues as well as to Dr. Elliott R. Weyer and other members of the scientific staff of that company for their encouragement, kindly constructive criticisms, and suggestions.

FIBROSARCOMA OF THE TONGUE AFTER INTERSTITIAL IRRADIATION

REPORT OF A CASE

PETER DELLER
M B Camb
LATE CANCER REGISTRAR, UNIVERSITY COLLEGE HOSPITAL, LONDON

In the following case a fibrosarcoma of the tongue developed nineteen years after interstitial irradiation at the same site.

CASE RECORD

A man, aged 48, was first seen in October, 1929. He then had a lump under his tongue, noticed for a month, and an ulcer measuring 2 by 1.5 cm., with hard raised everted edges on the left side of the undersurface of his tongue and extending into the floor of the mouth. The base of the ulcer was indurated, but induration did not extend appreciably beyond its edges. No glands were palpable in the neck. Carcinoma was diagnosed, and the growth was treated with interstitial radium in a total dosage of 1210 mg. hr., or about 10,000 r. A biopsy was not done. A fortnight later a gland dissection of both submaxillary triangles was done, followed a year

0

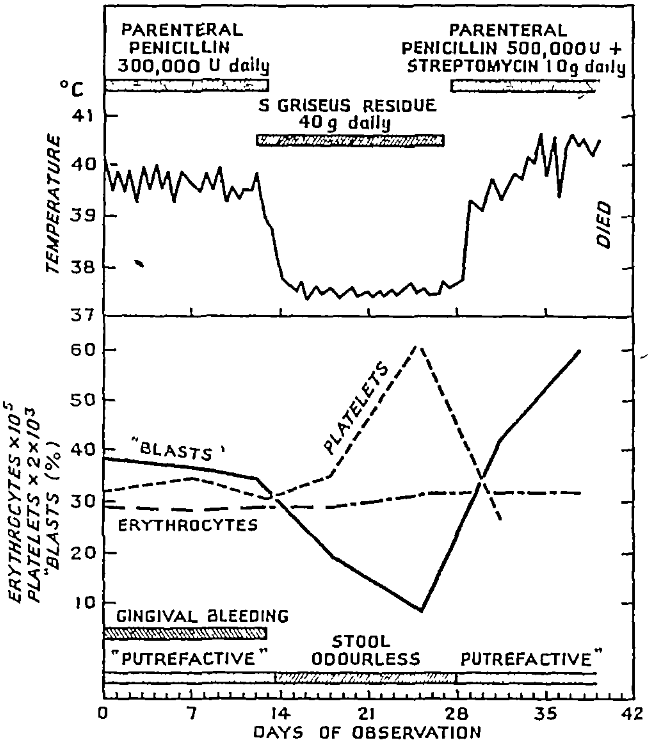

Fig 1—(Case 1)

within 48 hours of its discontinuance The patient died on Feb 2 from what was apparently a cerebral hæmorrhage, necropsy was refused

Remissions of the kind seen in this case are common even in untreated children (I regard them as the rule rather than the exception and have seen them occur merely on sending an unhappy sick child home from the hospital), but they are seldom spontaneous in adults What the graph cannot depict is the rapid reversal in course, under the same environmental conditions at home, amazing alike to the family and the attendants, during which the colour changed from corpse like to ruddy and the appetite became ravenous, within 48 hours after beginning to take the crude fermentation residue The latter, incidentally, turned out to be among those in which the presence of a coliform suppressor antibiotic, assayed as "streptomycin," was found accountable for the accelerated growth of chicks and hogs On the basis of subsequent calculations it appeared that the patient had been daily ingesting about 0 3 milligrammes of B_{12} and 8 0 milligrammes of antibiotic (in terms of streptomycin, aureomycin, terramycin, or chloramphenicol coliform suppressor equivalence) This amount could hardly have resulted in any significant distribution of the antibiotic through the blood stream, and it was also significant that parenteral penicillin and/or streptomycin did not alter the course of the disease Unfortunately, the stools were not examined bacteriologically, but it is probable that the emergence of resistant coli aerogenes strains in the intestinal flora coincided with the relapse, which had undoubtedly begun before the rejection and discontinuance of the fermentation residue

The fermentation residue contains vitamin B_{12} Though massive doses of the latter have been given parenterally in acute leukæmia without advantage, there may be differences in the pharmacodynamics of oral and parenteral B_{12}, at least in animals (Chow et al 1950) The next case permitted comparison of the two known components of the product used

Case 2 —A boy, aged 12, was treated at home from the middle of March, 1950, with a refractory "viral" pneumonia, and had daily injections of penicillin During the first week in April, splenomegaly and hepatomegaly were noticed On April 23, the peripheral smear showed a macrocytic anæmia with 13% of myeloblasts, marked thrombopenia, and a moderate erythroblastosis the sternal marrow showed marked "blast" infiltration, 70% of all nucleated forms being undifferentiated On the same day the child was transferred to the hospital, and was given, by mouth, 10 g daily of a streptomyces derived residue containing 55 µg of B_{12} per g but devoid of coliform suppressor substance During the next 12 days deterioration was rapid The spleen continued to enlarge, as did the cervical glands, and the patient was prostrated The temperature spiked higher each evening, reaching 41 7°C on May 5 Only by special pleading was a transfusion withheld, and on the morning of May 6 1 5 g of terramycin hydrochloride daily was substituted for the antibiotic free streptomyces concentrate The temperature was normal by the morning of May 8, and the child was out of bed The appetite had become voracious by May 10, and on the 14th, as it was evident that all glands, the spleen, and the liver were receding in size, he was allowed to go home in definite clinical remission

I must gratefully acknowledge the kindness of Dr Harry Bloch and Dr Margaret Rice, of the King's County Hospital, for permitting my supervision of the care while the child was there Later developments, which were reported to me, were less happy Though the hæmoglobin was definitely higher than during the hectic stage of illness, pressure for the orthodox transfusion ritual was resumed after the child had been home for some weeks Whether his death was the result of transfusion, I do not know, though in other cases I am more certain (Barnard 1951b)

As this patient daily ingested over 0 5 mg of B_{12} before he received any antibiotic, the question arises whether storage and continued activity of this vitamin was not responsible for the remission There is no way in which B_{12} can be completely eliminated from the human, since it is synthesised in the gut and stored in the liver, but it is significant that in our experience oral terramycin alone will usually induce some degree of clinical and hæmatological remission, oral chloromycetin does do so

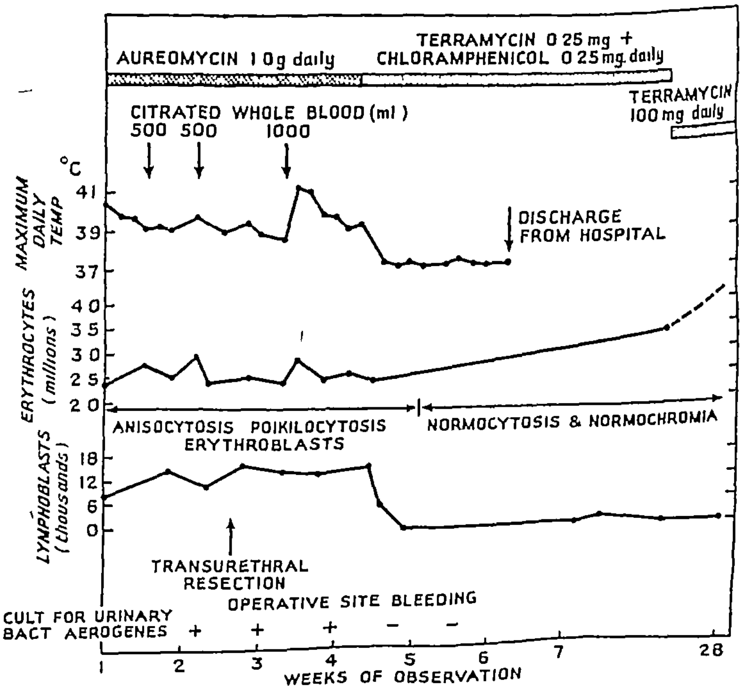

Fig 2—(Case 3)

eight expressed as a percentage of the normal standard woman of normal weight for height contains about % of fat, a man 16%

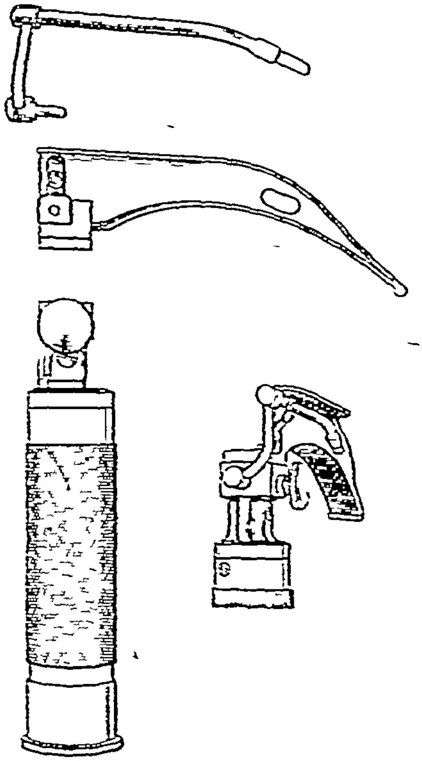
The highest figure obtained for fat was just over 60% r a woman weighing 25 stone This woman was carrying bout 15 stone of fat and she had no more muscular tissue han an under-weight person with which to do it

Dr D A W EDWARDS described two disorders of ubcutaneous fat—lipodystrophy and diffuse symmetrical pomatosis. The excessive tissue in lipomatosis is fat, nd Dr Edwards showed slides of paraffin sections of atty tissue taken from normal and obese persons and rom persons suffering from lipomatosis. He demonstrated learly that in an obese person the number of fat cells is ormal, but there is an excessive amount of fat in each ell. In lipomatosis the number of fat cells is increased, nd not the amount of fat in each cell. The fat cells espond normally to undernutrition, and the normal nd abnormal parts of the body lose equivalent amounts f fat. In lipodystrophy there is a local disappearance r loss of function of the fat-storing cells. It is quite ommon to get both disorders in the same patient

New Inventions

MODIFIED LARYNGOSCOPE

THE laryngoscope illustrated here is a modification of R. Macintosh's excellent design In this instrument he blade has been lengthened and its side-wall increased n depth This gives an improved view of the larynx and, by opening the mouth more widely, an increased area for manipulation.



The entire electrical system can be removed from the blade, so that the latter can be put into the sterliser without fear of ultimately damaging the electrical insulation. It also makes for easy replacement of the lens fronted lamp, when required This instrument was made for me by Messrs A. L. Hawkins, of 15, New Cavendish Street, London, W 1

Reviews of Books

Current Therapy, 1951

Editor HOWARD F CONN M.D Philadelphia and London W B Saunders. 1951 Pp 699 50s

Conn's *Current Therapy* should make a special appeal to the general practitioner, who will be grateful for a book on treatment which is both comprehensive and up to date. This volume, with its round dozen consultant editors and nearly 300 contributors, seems to have both these merits. It aims at providing a brief but complete resume, by one or more authors, of the treatment of all the commoner conditions met with in practice. No details of surgical operations are included, but the descriptions of methods available to the general practitioner are full and for the most part clear The indexing is excellent and quick reference either to symptoms or to diseases proved possible for all the conditions looked for—with the exception of Halitosis (which seems to be omitted from almost every book on treatment), Proctalgia fugax, and (unless hidden out of sight) Periarteritis nodosa. A number of useful diagrams are given, and a roster of drugs ' at the end includes most of the best-known proprietary preparations The therapeutic methods differ in places from those current here, but the book certainly offers authoritative views on present-day American treatment

Neurosis and Human Growth

KAREN HORNEY M.D London Routledge & Kegan Paul 1951 Pp 391 21s

Dr Horney's latest work is a welcome addition to her psychoanalytical theory The fact that this theory is still developing—through the amplification here of the ideas embodied in *Our Inner Conflicts* in particular—is an indication of its clinical and intellectual vitality

It is too early to assess the extent to which her system is likely to constitute a non-Freudian school. Her contribution to the understanding of neurosis seems to lie mostly in the social biology of neurotic disorder Her concept of psychodynamics—far less a psychology of the unconscious than that of Freud—is, in its own field, equally illuminating Like most therapists, nowadays, she is well aware of factors outside the rigid Freudian canon of trauma, especially social factors, but she has a rather uncritical readiness to transfer conscious constructs to the patient. Modern anthropological work increasingly forces us to recognise the effect of social factors, and these are something which Freudian psychodynamics in their original form have not proved flexible enough to interpret satisfactorily It is in bridging this gap that Dr Horney's work has particular value She points the way to a full ultimate synthesis, not only between the sociological and Freudian approaches to mental ill health, but between the classical traumata and the conception of behaviour disorder (delinquency in particular) as a situation neurosis conditioned by faulty relationships. Her terminology is clear and will be welcome to teachers of social psychology

The therapeutic implications of Dr Horney's work extend throughout education politics, and social institutions This is a valuable book.

Contraceptive Technique

HELENA WRIGHT M.B London J & A. Churchill 1951 Pp 68 6s

THIS is a good short book which could well be in the hands of every general practitioner and medical student it is concise accurate free of fads and full of useful information especially in dealing with gynæcological difficulties which may modify the technique of choice. Dr Wright's ten-page survey of the scope, objects and requirements of contraception under modern conditions is a model of good sense, with which the rest of the book is in key Clinic and private-practice routine methods are well outlined the psychological background is at least as much in the author's mind as the hygienic. A brief account of contraceptive methods suitable for use in the tropics, or in countries which prohibit the sale of proper appliances, and an account of the British Family Planning movement, up to the report of the Royal later (i e , December, 1930) by a formal left block dissection None of the glands was reported as containing carcinoma, and the growth regressed satisfactorily The patient was seen regularly for nearly 19 years after this, and no evidence of recurrence was found

In September, 1948, he noticed another lump in his tongue, and reported immediately to hospital Deep to the irradiation scar was a firm irregular ill defined mass 1 5 cm in diameter No masses were palpable in the neck In October, Mr A J Gardham performed a left hemiglossectomy The excised portion included the left side of the floor of the mouth and the sublingual gland, and showed a grey fibrous tumour 1 cm. in diameter surrounded on every side by about 0 75 cm of apparently normal muscle On section a fibrosarcoma of low grade malignancy was reported by Prof G R Cameron There was no sign of recurrence up to 27 months later (December 1950)

DISCUSSION

Without histological proof one cannot say whether the original growth was a sarcoma or a carcinoma

If it was a sarcoma its clinical features were atypical (Ross 1935) and its local recurrence after 19 years was most unusual When a sarcoma recurs it usually does so within a few months, according to Koerth et al (1943), who summarised the published accounts of 61 primary sarcomas of the tongue

If the original growth was a carcinoma, the appearance of a sarcoma at the same site following interstitial irradiation is worth noting Nearly all the reported cases of irradiation sarcoma have followed protracted irradiation , Wilson and Brunschwig (1937) reported and reviewed 26 such cases However, one sarcoma occurred in a rabbit 18 months after a 1 mg, radium needle had been implanted at the same site for 20 days (Schürch and Uehlinger 1931) , and Gricouroff (1937 1943) described 4 human cases, of which 3 had a proved carcinoma of the tongue treated by interstitial irradiation, and fibrosarcomata developed at the same site after 12, 4, and 4 years , and the 4th case was one of carcinoma of the buccal aspect of the cheek in which a fibrosarcoma appeared at the same site 12 years later There is thus no doubt that sarcoma of the tongue sometimes develops after interstitial irradiation , but these cases are so rare that it is impossible to be certain whether there is any causal connection between the irradiation and the tumour

I am most grateful to Mr Gardham for his encouragement and his permission to publish this case , and to Professor Cameron for the pathological report

Medical Societies

ROYAL SOCIETY OF MEDICINE

Experimental Approaches to Obesity

The section of experimental medicine of the Royal Society of Medicine met on May 8, with Prof R A McCance, F R S , president of the section, in the chair

Dr G C **Kennedy** described his work on experimental hypothalamic obesity in rats If the tuberal part of the hypothalamus of rats is damaged by electrolytic lesions the animals become very fat The cause of this obesity is overeating From the first day after operation the animal eats 2–3 times as much as normal , this hyperphagia goes on for 4–6 weeks, by which time the rat weighs about 50% more than an unoperated animal of the same age The increase in weight is entirely due to the deposition of fat, and the amount of water in a fat animal is exactly what one would expect in a normal animal of the same length. Even when the operation is performed on an animal which is still growing the body length is unaffected, the obese operated animal being exactly the same length as its unoperated control.

Rats with hypothalamic obesity seldom survive for more than a year after the operation The first signs of ill health are that the skin undergoes trophic changes and pressure sores appear on the feet After 8–10 months gross kidney damage ensues, with severe albuminuria and enlargement of the kidneys The adrenals are the only other organs which are hypertrophied The lesions in the kidney all lie in the tubules There is no vascular damage, and the glomeruli are unaffected The histological appearance is of pyelonephritis, and is similar to that produced by non specific stresses of various kinds

Dr Kennedy described experiments in which operated and control rats were fed unlimited amounts of the stock diet mixed with an equal bulk of kaolin The control animals responded by eating twice their usual amount so that their calorie intakes were unaltered The operated rats seemed unable to increase sufficiently their already high consumption of food, so that their calorie intakes were reduced Dr Kennedy concluded from this that calorimetric control is paralysed by operation on the hypothalamus The nature of the stimulus to which the hypothalamus responds is still a matter of controversy

Captain A R **Behnke**, speaking on measurement of the fat and water content of the body in relation to obesity, emphasised the distinction between the terms " overweight " and " obesity " Football players are very often overweight, and are turned down on this account by the insurance companies regardless of the fact that their excess weight consists largely of muscular tissue Obesity implies that the excess weight consists of fat

As a rough guide to leanness and fatness Captain Behnke recommended the comparative girths of the chest and the abdomen In lean men the chest measures about 8 in more than the abdomen, but in fat persons the abdomen measures more than the chest Captain Behnke went on to describe results which he has obtained on 100 naval personnel by measuring their specific gravities A body with a specific gravity of 1 100 has no excess fat at all Every addition of 1% fat to the body weight will cause the specific gravity to decrease by 2 units (i e., 0 002) Most people have a specific gravity between 1 090 and 1 050, which corresponds to fat contents of 5–25% Comparative measurements on a few obese subjects have shown that a reduction in body weight is solely at the expense of fat

It is not practicable to make specific gravity measurements on patients , but if advantage is taken of the fundamental concept that the fat free body tissue is of uniform structure, all that is necessary for the assessment of the amount of fat in the body is determination of the total body water

Miss E M **Widdowson**, D SC , described a method which she and Professor McCance have used for breaking down the body weights of living persons into terms of extracellular fluid, cell mass, minerals, and fat The extracellular fluid and total body water are estimated directly, and the difference between them is taken to be the intracellular water This, multiplied by $\frac{100}{0}$, gives the cell mass The minerals have been shown by direct chemical analysis of human bodies to comprise 7% of the fat free body weight, so that all the information is now available to enable one to determine " by difference " the total amount of fat in the body

Results obtained by this method for the amount of water and fat in 30 normal individuals, fat and thin, and in 10 undernourished German men before and after rehabilitation, were described and a slide was shown relating the percentage of fat in the body to the body-weight expressed as a percentage of the normal standard. A woman of normal weight for height contains about 17% of fat, a man 16%.

The highest figure obtained for fat was just over 60% for a woman weighing 25 stone. This woman was carrying about 15 stone of fat, and she had no more muscular tissue than an under-weight person with which to do it.

Dr D. A. W. EDWARDS described two disorders of subcutaneous fat—lipodystrophy and diffuse symmetrical lipomatosis. The excessive tissue in lipomatosis is fat, and Dr Edwards showed slides of paraffin sections of fatty tissue taken from normal and obese persons and from persons suffering from lipomatosis. He demonstrated clearly that in an obese person the number of fat cells is normal, but there is an excessive amount of fat in each cell. In lipomatosis the number of fat cells is increased, and not the amount of fat in each cell. The fat cells respond normally to undernutrition, and the normal and abnormal parts of the body lose equivalent amounts of fat. In lipodystrophy there is a local disappearance or loss of function of the fat storing cells. It is quite common to get both disorders in the same patient.

Dr Wright's ten-page survey of the scope, objects, and requirements of contraception under modern conditions is a model of good sense with which the rest of the book is in key. Clinic and private-practice routine methods are well outlined; the psychological background is at least as much in the author's mind as the hygienic. A brief account of contraceptive methods suitable for use in the tropics or in countries which prohibit the sale of proper appliances and an account of the British Family Planning movement, up to the report of the Royal

Commission on Population, round it off Moreover a book of this kind should have a wide circulation in countries where the development of contraception and the training of advisers are becoming economic necessities Those wishing for a more detailed account of the scientific background of the subject will need to consult larger works, such as *Problems of Fertility in General Practice*, published in 1948 and sponsored by the Family Planning Association.

Die Entzündungsbestrahlung

(2nd ed) Dr Habil R Glauner, Dozent für Röntgenologie und Strahlenheilkunde, Chefarzt der Röntgenabteilung am Marienhospital, Stuttgart Stuttgart Thieme 1951 Pp 189 D M 18 60

THE first edition of this book on the radiation of inflammatory conditions was published in 1940, this second edition leaves the first part, which explains the action of radiation, little changed, but brings the second part, which deals with treatment, more up to date

Dr Glauner discusses biological reactions on conventional lines, and concludes that the localised effect of X radiation is mainly due to its effects on leucocytes and lymphocytes, and to increased enzymatic processes at the site of an inflammatory lesion These effects are produced by very small doses, ranging from 10 r in acute, to 20 r in chronic, inflammations Very small doses are given daily, higher doses at longer intervals The results of treatment on these lines, for a large variety of inflammatory lesions, are discussed at length Lesions which respond particularly well are furuncles of the face, carbuncles, infections of sweat glands, and puerperal mastitis Other conditions which benefit when treated by the techniques described are tuberculous lymph nodes, and infections of the tonsil and other regions in nose and throat, postoperative parotitis, some forms of pneumonia, and certain chronic gonococcal infections The pain and disability of some forms of chronic arthritis can be relieved Radiotherapy can therefore be useful in the treatment of many diseases when combined with other forms of treatment, chemotherapy in particular There is an extensive bibliography, and the book can be recommended to radiotherapists studying the treatment of these inflammatory lesions

Nobel The Man and His Prizes

Editors The Nobel Foundation Stockholm Sohlmans Förlag 1950 Pp 620 Sw Kr 30

THIS important book contains not only surveys of the sciences as exemplified in the awards, together with an account of the awards in Literature and Peace, but also what to the general reader may be of even greater interest, a penetrating analysis of the character of one who was little known to the public

Alfred Nobel, as an inventor of genius, of many things besides dynamite, could hardly escape becoming a man of great wealth Yet at no time did he obtain happiness Born in Sweden and never losing his affection for his country, he was so cosmopolitan that he wrote with greater facility in English and perhaps in German, than in his native tongue The poetry which poured from him as a young man, under the influence of his passion for Shelley, was English poetry, by no means without merit When not travelling on the business of the many undertakings which he controlled, he lived for long in Paris and at the end of his life in Italy a retiring, sensitive soul, considerate of others, detesting all publicity, always an idealist and always alone Once, ill and lonely, he wrote 'I can see in my valet's eye how much he pities me, but I cannot of course let him notice that "

In his life Nobel was always a generous giver but one who discriminated "My natural inclination is less to honour the dead who have no feelings and who must be insensible to our marble tributes than to help the living who suffer want " In a short will of doubtful validity he left his great fortune to found the prizes that we know, and it is interesting to read how dubious were many of the leading personages and institutions of Sweden as to the wisdom of accepting the trust By many it was thought "a magnificent intention and a magnificent blunder ' Only after protracted discussion and a bitter struggle for four years was the final realisation of Nobel's wishes achieved Today the task of distributing the prizes is regarded by all Sweden as a privilege

In the account of recent awards an interesting light is thrown upon the mentality of Hitler When Professor Domagk was invited to receive the prize, Hitler, who had never heard of the 'Prontosil' which was exciting all Europe and who advisers were unable to enlighten him, had Domagk's hou surrounded by armed guards and hurried him to prison. T Hitler it was clear that a professor who received an awar from a foreign nation could only have earned it by betrayin his own

The Meaning and Practice of Psychotherapy

V E Fisher, ph d, formerly director of the Menta Hygiene Clinic, New York University New York an London Macmillan 1950 Pp 411 37*s* 6*d*

ALTHOUGH written in a pleasanter, less involved style than most American books on this subject, the present volume fails to shed much light on the first part of its title Dr Fisher's theories about the psychopathology of the mental disorders he treats are not discussed at much length From his first section, on the approach to the patient and procedure, and from his bibliography, it may be inferred that he has a very open mind and does not feel bound by any of the orthodoxies, but this eclecticism results in some oversimplification of theory The three following sections, which comprise the bulk of the book, are more rewarding, for they contain over 20 case histories, showing Dr Fisher's methods of handling various conditions—psychotic, psychoneurotic, and socially maladjusted Perhaps the most interesting case is that of an early schizophrenic treated by what Dr Fisher calls "psychic shock," though the cases of phobia and of suicidal tendencies are also most unusual In this as in many other books on psychotherapy the contrast between obscure, even debatable, theories and the intuitive sureness of their proponent when it comes to dealing with a patient is curious Possibly psychotherapy has always been more a matter of deep calling unto deep than we like to think nowadays

Pediatric Allergy

Robert Chobot, m d, assistant clinical professor of pediatrics, New York University—Bellevue Medical Center New York and London McGraw Hill 1951 Pp 284 38*s* 6*d*

Dr Chobot's teaching on allergic problems in children is well known in America He has set out in this book the basic facts of pædiatric allergy that he has gleaned from his experiences The book could be said to be a synopsis of the clinical aspects of diagnosis and treatment of allergic complaints in children and, though it was not the author's intention to make the book a general synopsis on allergy, it could well serve this purpose It is easily and quickly read, though at times, in compressing his subject matter, Dr Chobot makes dogmatic statements which might be misleading to a student Thus he says that the term migraine should be reserved for the condition in which patients have unilateral headaches associated with nausea and vomiting, later, nausea and vomiting rather than headaches are said to be the prominent symptoms in young children But on controversial questions he usually presents both sides He knows that some will take issue with him over the importance he gives to focal infection, particularly over the frequency with which he advocates the removal of tonsils and adenoids Though he is hopeful of progress in the development of more effective anti-histamine drugs, he rightly observes that they are of no great use in asthma, where they can only be used for sedation The last part of this very reasonable book is taken up with illustrative case histories to bring out points in diagnosis and treatment

---

Blood Clotting and Allied Problems (New York 1950 Pp 224 $3)—The Josiah Macy, Jr, Foundation's Third Conference on this subject, held in January, 1950, gave most of its time to discussing anticoagulants and their control, with special emphasis on the newly introduced substances 'Tromexan,' phenylindandione, and paritol Six papers in this volume, edited by J E Flynn, deal with problems connected with prothrombin, one deals with the effect of surfaces on blood coagulation, and one with the application of zeta potential measurements for studying blood clotting All the papers are very technical but the volume remains of interest to specialists in the field, mainly because of the verbatim reports of the discussions, which seem reasonably uninhibited

THE LANCET

LONDON: SATURDAY, MAY 26, 1951

International Sanitary Regulations

LAST month a special committee, consisting of government delegations, met in Geneva to consider the final text of the new International Sanitary Regulations which it is proposed shall replace the existing International Aerial and Maritime Sanitary Conventions. The text had been worked on for three years by the World Health Organisation's expert committee on epidemiology and quarantine and by the secretariat of W.H.O., and had been sent to governments for comments, so it was already in a form likely to find general support. International quarantine discussions necessarily end in a measure of compromise between those countries which are highly receptive to the diseases in question, and therefore require the maximum protection, and those whose interests are mainly in international trade and which insist on the minimum interference with shipping and aircraft on international trade routes. On this occasion, however, there was a third group which held that the best protection for all countries against importation of disease is the immunisation of all travellers as a condition of international travel. With Dr. M. T. MORGAN in the chair, the committee was in session for four weeks, during which the argument centred round these conflicting interests, but the final text did not differ greatly from the original. It is hoped that the W.H.O. Assembly, now meeting in Geneva, will accept this text, so that the new regulations will then be open to governments for acceptance.

The procedure on this occasion differs from that used for previous conventions. Governments will not now have to sign and ratify these new regulations individually, for they will come into force for all members of W.H.O. after a stated period. During this period governments may only contract out of the regulations as a whole and cannot make reservations substantially changing the intention of the regulations. For this reason any reservation made by a government must first be submitted to the Assembly, and, if it is rejected, the government concerned must either withdraw the reservation or reject the regulations as a whole. In the latter case the existing conventions will remain in force if the country concerned has ratified them. The new regulations provide for a continuous review of their working which will enable any amendments or additions to be made without the need for an entirely fresh set of regulations on each occasion. If a dispute arises between governments on a quarantine matter, W.H.O.'s existing machinery for dealing with it will be used, but if necessary a suitable committee may be convened to consider the case. There is also the final remedy of an appeal to the International Court of Justice. The measures prescribed in the regulations are to be regarded as maxima, and no country is likely to apply them in full.

The recent advances made in methods of destroying insects have been recognised by the abolition of some of the older measures in force for dealing with typhus, relapsing fever, and plague. Measures against yellow fever remain largely unchanged, but there is now a clause that allows local areas which keep the aedes index below 1% to be excluded from the yellow fever endemic zone. The smallpox and cholera measures have been simplified, though the measures themselves have been somewhat intensified: for instance, travellers on an international journey may be required to possess a certificate of vaccination against smallpox, but if they come from a local area infected with smallpox they *will* be required to possess such a certificate, or to submit to vaccination, or failing this to be isolated for the unexpired portion of the incubation period. The certificate of vaccination against smallpox has been revised: it will no longer contain a record of the result of vaccination but will become available immediately for three years from the date of vaccination. As regards cholera, stricter measures are now to be permissible; persons arriving from an infected local area within the incubation period of the disease may be isolated for the remainder of that period, unless they have a valid certificate of inoculation against cholera. Rectal swabbing and stool examinations of healthy persons are not permissible measures under the new regulations. The six diseases to which the regulations apply—cholera, plague, yellow fever, smallpox, typhus, and relapsing fever—are now to be termed the “quarantinable diseases,” while the other infectious diseases for which no provisions are yet made in the regulations will be termed “epidemic diseases.” Proposals were discussed in the committee for removing typhus and relapsing fever from the scope of the regulations as well as for establishing the maximum measures which may be applied for “epidemic diseases.” Both proposals were dropped for the time being, though they will no doubt be raised again in the course of the work of review of the regulations.

Generally speaking it can be said that these regulations, if accepted, will be an important advance and will place the international system of quarantine on a more rational basis. A point of great importance is that there is now a convenient procedure for altering and revising the quarantine regulations at suitable intervals, to conform with advances in science and with changing epidemiological conditions.

Drugs in Amœbiasis

THE pandemic of virulent amœbiasis that was widely predicted to mark the homecoming of expeditionary forces at the end of the late war has not materialised. In the U.S.A. the post-war rise in incidence seems to have been no greater than might be expected from improved diagnostic techniques and amœba mindedness among both doctors and the public. The American outlook has in places amounted to a phobia, and there has been a tendency for some clinicians to ascribe nearly every case of chronic looseness of the bowels to amœbic infection, and for some pathologists to report nonpathogenic strains as *E histolytica* BARGEN [1] and other American authorities look now on the "amœba-carrier" as a person suffering from amœbiasis which is not causing manifestations severe enough to send the patient to his doctor , in fact most of these people have symptoms of the infection, though they are not necessarily those of colitis

The ideal amœbicide should be active by mouth , it should kill the organism in the trophozoite or cystic stages in the lumen of the gut, and should reach the liver and other infected tissues in a concentration high enough to deal effectively with trophozoites , and its toxicity must be low No known drug satisfies all these criteria The amœbicides now in use are of three classes First, there are those like emetine, carbarsone, and 'Vioform' which when given systemically will kill amœbæ in either bowel or tissues , they presumably act directly on the amœba, since they have little if any effect on associated bacteria or protozoa The second class act indirectly by rendering the bacterial flora of the intestine unfavourable for amœbæ , these include penicillin and some other antibiotics (probably 'Aureomycin' acts directly), sulphonamides, and hydroxyquinolines like chiniofon and 'Diodoquin' These may clear the lumen of the bowel of *E histolytica* but are not effective if the tissues have been invaded Unfortunately they only clear the bowel of the parasites for a few weeks or possibly months, and when the normal bacterial flora returns the pathogenic amœbæ flourish once more The third class of drug, exemplified by chloroquine, are concentrated in the liver and act well in amœbic hepatitis, but much less on the amœbæ inside the colon For this reason a combination of amœbicides is often more effective than any one alone Improved methods of in vitro testing have made it possible to see whether an amœbicide acts directly on the amœba or on commensal organisms in the gut

Several workers have been studying the effect of antibiotics in amœbic dysentery Penicillin is used only as an adjunct to other treatment,[2] since its therapeutic effect must be on the secondary bacterial invaders rather than on the amœba itself, which is resistant in vitro to concentrations of penicillin as high as 10,000 units per ml [3] FAUST [4] noted that 'Bacitracin' is amœbicidal and MOST [5] found that this antibiotic not only ends acute amœbic dysentery but also eliminates the amœbæ from the stools of two thirds of the patients treated It apparently acts selectively on clostridia and enterococci, as well as on other gram-positive organisms, but it does not prevent the subsequent reappearance of amœbæ in the stools , 80,000 units by mouth daily for 10 days is recommended Aureomycin seems to be even more promising McVAY and colleagues [6] treated 37 cases with 2 g daily for a week with good results in 36 , symptoms were quickly relieved and the carrier state eliminated MOST et al [7] treated 100 cases with satisfactory results, though 10% relapsed after 10 days' treatment ARMSTRONG and others,[8] working in the Amœbiasis Research Unit at Durban, obtained an immediate cure rate of 94% —higher than with any other single agent—but the relapse rate was high In their view aureomycin is the drug of choice in acute ulcerative amœbiasis, but it should be given with other drugs, such as diodoquin, to prevent the relapses commonly seen in the first month after a course of aureomycin alone HALL,[9] who has been treating acute and chronic cases in veterans at Minneapolis, reports good results in chronic amœbic dysentery and in cyst-passers (i e , "carriers," now usually looked on as chronic cases of amœbiasis) , but he emphasises that "aureomycin should not be used alone in hepatic amœbiasis, but should be supplemented by emetine hydrochloride or chloroquine, or both " In his hands, chloramphenicol has been less effective than aureomycin against amœbæ in vitro THOMPSON et al [10] found that chloramphenicol would suppress amœbic colitis in dogs, but only temporarily , it worked better against cæcal infections in rats but had not yet been tried in human infections The amœbicidal activity of some of the new antibiotics have been compared by WATT and VANDEGIFT [11] They head the list with polymyxin B and aureomycin, followed by polymyxin E BARGEN [1] cites some excellent clinical results with 'Terramycin', and lately McCOWEN et al [12] have shown that 'Fumagillin' or H3, an antibiotic obtained from a species of aspergillus, will inhibit the growth of *E histolytica* at a dilution of 1 in 120 million in the presence of the intestinal bacterial flora, and will eradicate amœbic infection in rats in a dosage of 9 mg per kg If this newest recruit is well tolerated by man it may well be the best amœbicide among the antibiotics

Among other new drugs introduced for amœbiasis are 'Milibis' and chloroquine Milibis, or 'Win,' the bismuth derivative of *p*-N glycolylarsanilic acid, originally studied in infected kittens in Germany in 1943,[13] has been submitted to clinical trial in the United States by DENNIS, BERBERIAN, and HANSEN [14] It is not absorbed and so can only act locally in the bowel Sixty-two out of sixty eight cases were cleared of amœbæ after taking 0 5 g three times a day for a week, but further investigation is needed Chloroquine [7-chloro-4-(4-diethylamino 1 methyl butyl amino) quinoline] has given encouraging results as an amœbicide [15] It is concentrated in the liver, the concentration in that organ being 400 to 600 times that in the plasma [16] A dose of 0 3 g twice daily for two days and then 0 3 g daily for an additional twelve to nineteen days is a valuable adjunct in the treatment of amœbiasis with liver involvement Chloroquine, despite its somewhat lower effectiveness in intestinal amœbiasis, is a satisfactory substitute for emetine in hepatic amœbiasis, and is considerably less toxic than emetine apart from mild gastric disturbances chloroquine appears to be relatively free from side effects Emetine is still favoured for the treatment of amœbic hepatitis, but care is required in its administration since in dosage slightly in excess of that used therapeutically it is a protoplasmic poison If the claims for chloroquine stand the test of time this drug may eventually replace emetine in the treatment of amœbic hepatitis

Carbarsone, a trivalent arsenical compound, is often used in conjunction with emetine If the oxygen attached to the arsenic atom of carbarsone oxide is replaced by a sulphydryl group (SH) the toxicity is reduced Substitution of the hydrogen atom of the SH group by methyl or phenyl groups, and carboxylation of these to render the compounds soluble, results in amœbicides with an activity greater than that of the parent substance[16] After their administration arsenic can be detected in the bile, liver, kidneys, and intestinal tract Preliminary tests in man have shown that two of these compounds are about 90% effective against trophozoites in tissues and cysts and in the lumen of the colon[17 18] All arsenicals are, however, potentially toxic, and such compounds cannot compare in safety with antibiotics such as aureomycin and terramycin

The problem of relapse may be solved by using a combination of drugs ARMSTRONG, WILMOT, and ELSDON-DEW[8] found a combination of penicillin and sulphasuxidine, followed by emetine and diodoquin, 95% effective They believe that the dose of emetine could be drastically reduced if it were used with aureomycin, and that the combination of diodoquin with aureomycin would reduce the relapse rate still further

Mental Health and the Mother

"EVERY kind of parent makes a hash of it" is a despondent aphorism born of modern psychiatric teaching, but there is some comfort for parents in the more recent view that deprivation of parental love—and even deprivation of the love of bad or incompetent parents—makes a super-hash, a kind of witches' brew Dr JOHN BOWLBY, whose work on this theme is well known, has lately made, on behalf of the World Health Organisation, a report on *Maternal Care and Mental Health*,[19] as a contribution to the United Nations programme for the welfare of homeless children His review of the evidence of the effects on the child deprived of the care of his mother during his early years is extremely impressive Studies fall into three classes (1) direct studies made on the mental health and development of children in institutions, hospitals, and foster homes, (2) retrospective studies of the early histories of adolescents or adults who have developed psychological illnesses, and (3) follow up studies of groups of children deprived of maternal care in their early years It is noteworthy that all these studies, undertaken ' by people of many nations, varied training, and, as often as not, ignorant of each other's conclusions," very largely confirm and support each other Indeed, only three, all follow-up studies, throw any doubt on these conclusions Numerous careful direct studies indicate that, when young children are deprived of maternal care, their physical, intellectual, and social development is retarded, and retrospective and follow up studies make it clear that in some children the damage is serious and permanent All children under the age of about seven years seem to be vulnerable, and the effects have in some cases been noticeable in the first few weeks of life Among the direct studies quoted is that of H DURFEE and K WOLF who (using the Hetzer-Wolf tests) compared the developmental quotients (D Q) of 118 infants in various institutions, and correlated the results with the amount of maternal care the infants received They found no difference between normal and deprived children in the first three months, but differences steadily increased from that time onwards, and children who had been in institutions for more than eight months during the first year showed such severe psychiatric disturbances that they could not be tested The picture of the institution baby has been drawn by H BAKWIN from his own observations, as follows

> "Infants under 6 months of age who have been in an institution for some time present a well-defined picture The outstanding features are listlessness, emaciation and pallor, relative immobility, quietness, unresponsiveness to stimuli like a smile or a coo, indifferent appetite, failure to gain weight properly, despite the ingestion of diets which, in the home, are entirely adequate, frequent stools, poor sleep, an appearance of unhappiness, proneness to febrile episodes, absence of sucking habits"

Those who have seen R A SPITZ's film, *Grief, a Peril of Childhood*, will be aware how accurate is this description of the baby deprived of his complementary partner

SPITZ and K M WOLF have made systematic studies of four groups of children—three in which the babies were with their mothers, and one in which they were not Absolute levels of development differed according to social group, but babies living with their mothers showed no change in D Q during the year On the other hand, the 61 infants brought up in a hygienic institution, and kept in relative isolation in cubicles, showed a catastrophic drop in D Q between the ages of four and twelve months, from 124 to 72, by the end of the second year the D Q had sunk to 45, and the infants were gravely retarded Other studies, notably those by W GOLDFARB, show similar retardation in older institutional children In a thorough study of 30 children aged between thirty and thirty-five months, half of them in an institution and the other half in foster-homes, GOLDFARB found a difference of 28 points in the intelligence quotient (Stanford Binet test) between the two groups The institution children had an average I Q of 68—on the borderline for mental defect—while the children in foster-homes averaged 96 BOWLBY notes that such findings are often questioned on the ground that many children in institutions come of poor stock, physically and mentally, heredity, it is suggested, might account for the differences But, as he points out, the investigators in most of the studies he cites have taken care to ensure that their control groups are of a similar social class and spring from a similar stock

The picture of apathy and retardation described by Bakwin is produced most commonly in children who have had a happy relationship with their mothers up to six or nine months, and have then been suddenly separated from them. Of 95 children studied by Spitz and Wolf, 20% reacted to separation by a severe depression, and 27% by a mild depression; this was considered to be the normal response. Most of those who escaped such depression had not had a close and happy relationship with their mothers, which suggests that their development was already damaged and their later capacity for love likely to be impaired. If the mother returns, recovery may be rapid and striking; but the longer she is away the more serious and lasting the damage, and the less the likelihood of complete recovery.

Retrospective studies suggest how serious the damage may be. In the '30s several independent workers noticed that those young delinquents who seem to have no capacity for affection or feeling for others had often had seriously disturbed relationships with their mothers in early years. Such children were often persistent thieves, violent, and egotistical, and sometimes guilty of sexual misdemeanours. If the disturbed relationship was a cause of the delinquency, as seems probable, society has a direct interest in preventing the separation of young children from their mothers. In a group of 44 young thieves whom Bowlby himself studied, 14 were of the "affectionless" type, and 12 of the 14 had experienced separation from their mothers in early childhood. Among a control group of 44 emotionally disturbed children who did not steal none were affectionless, and only two had been separated from their mothers. Goldfarb's comparisons of 15 children who had spent their first three years in an institution and 15 who had not, show a remarkable difference in such functions as intelligence, ability to conceptualise, reading, arithmetic, social maturity, capacity for friendship, and speech. In every instance the control group excelled the institutional children, often considerably. Three studies run counter to the general findings. S. Z. Orgel has given a not very detailed or systematic account of 16 institution children, among whom he found only 2 with adverse personality features; F. Brown judged that 100 institution boys aged between nine and fourteen were no more neurotic than 100 of the same age living at home in bad surroundings; and F. Bodman, having found that 51 institution children had a lower social maturity score (Vineland scale) than 52 children living at home, regrouped all the children according to heredity, and found exactly the same difference. He concluded that constitutional factors are at least as important as environment, but Bowlby considers that the statistical methods applied were not above criticism.

In the main the evidence is remarkably consistent and impressive; and Bowlby holds that the case is now proved. If so, what are the remedies? They are urgently needed, he believes; for these deprived children grow up into ill-adjusted adults, and reproduce in their own families the conditions which led to their own disablement. This is confirmed by the experience of psychologists and sociologists: deprived unhappy children grow up to make unsuccessful marriages in which discord, desertion, separation, and divorce are commonplaces; and they are thus poor parents. In this context he mentions the growing value of marriage guidance; and he might have added guidance about venturing on marriage at all. The notion that marriage is an exacting adult experience is not very general nowadays; it might well be more widely taught.

Bowlby proposes some important preventive measures. First we need more research into the effects of deprivation. It would be useful to know, for instance, the length of time during which separation of the child from the mother can be permitted with safety, to allow for making good the damage done. Again, personality growth depends on the interaction between the growing child and the people about him, especially his mother, and we need closer studies of this process. Experiment presents obvious difficulties, but some of Liddell's work with animals is proving enlightening. Systematic clinical and psychometric studies of institutional and delinquent children could give further information and so, he thinks, could physiological and electro-encephalographic investigations. Meanwhile some social preventive measures suggest themselves. Bowlby warns against a vested interest in the institutional care of children, and the temptation to suppose that because a child looks clean it must be well and happy. A rather grubby child playing boisterously in the home of its loving but feckless parents may be growing into a more mentally healthy citizen than a docile and physically cherished child in a clean bare ward. He is no lover of day-nurseries; not only do they separate mother and child for many hours of the day, but their rates of infection are high. Moreover, they are costly to run (£3 per head per week), and for every 100 women they release to industry they employ 50 to look after the children. We should give up the idea that because a mother is running her home badly she should be deprived of her children; it is often not only easier, but much cheaper, to give her some material help with the rent and the housework. Bowlby quotes the saying of Sir James Spence that at present mothers are "relieved of their children when they should be relieved of their chores." He also puts the case for the child detained for long months or years in hospital for orthopædic or other treatment. Most of these can spend their time at home between operations, and their segregation from normal life is damaging and unnecessary. When a young child must be separated from his mother—when she dies, or abandons him, or is kept from him by sickness or imprisonment—then he should whenever possible be provided at once with a substitute, a foster mother with whom he can make the same strong personal link that he should have made with his own mother.

Bowlby concludes a capable survey of many other aspects of this world-wide social problem by comparing our present position to that faced by the pioneers of public health a century ago. We must take action now, even though our evidence is incomplete; for "it must be remembered that evidence is never complete, that knowledge of truth is always partial, and that to await certainty is to await eternity." In this case, to await certainty may well be to await a spreading of our present social sickness until it is beyond all cure.

Annotations

HOUSING FOR SPECIAL PURPOSES

BOTH humane and economic considerations have directed attention to the housing of old people. A new booklet[1] on this subject goes further afield to study the accommodation required for single workers, including students and apprentices, dwellings for disabled persons, and the special needs of district nurses and midwives. There are even a few kind words for the house hungry higher income groups.

The recommendations dealing with the aged emphasise the importance of cooperation between the housing and the welfare authorities, especially at the moment when responsibility passes from the one to the other. The old people should be conscious of this close-working arrangement "they should not be troubled by the possibility of passing from familiar surroundings (the home or the room they have known for many years) to a completely strange place administered by strangers." In examining the various types of dwelling the committee have given much thought to hostel accommodation, for which an Exchequer subsidy is now payable under the Housing Act, 1949. They take the view that each hostel should provide for about 30 old people. The building should not have more than two storeys, and it should be planned for communal rooms, dining-rooms, kitchen, and some bed sitting rooms on the ground floor, with the rest of the bed sitting rooms and the warden's flat above. The building should be centrally heated, with a radiator in every room and, in addition, open fires in the communal rooms. It is rightly urged that each single old person should have a separate bed sitting room they all want to have *one* room of their own. The equipment suggested for the bed sitting rooms is admirable each with a fitted washhand basin, a built in cupboard with hanging space and shelves, an electric fire, a good central light, and a point for a bedside lamp. An electric bell near the bed is also an essential fitment. There is a further useful suggestion to fit up a number of guest rooms in each hostel.

The proposals for self contained dwellings follow the traditional pattern, but the committee go further than the Housing Manual in suggesting an auxiliary means of water heating by gas or electricity. They lay just emphasis on protection against fire, but almost in the same breath they say that a coal fire should always be fitted in the bedroom. The two proposals are incompatible. A coal fire is *not* safe in a bedroom of 120 sq. ft or thereabouts, even when a kindly authority provides a fireguard. Coals drop out, and bedclothes leap to meet them. Why not a properly guarded gas or electric fire, or a hot water radiator as recommended for the hostel bedrooms? Another curious anomaly, explicit under the heading of hostels and implied in the separate dwellings, is that the w.c. should not be combined with the bathroom. No reason is given for this out of date advice, but it is well known that elderly people have increasing difficulty in maintaining cleanliness after using the toilet, and that the narrow, cold cell which constitutes the w.c. in England is the sworn enemy of hygiene. The committee show a common sense attitude towards the siting of dwellings, recommending that some of them should be dispersed among ordinary houses. At the same time there is a need for cottages in groups for old folk who prefer to live among people of their own generation. These grouped dwellings should be provided in each residential district in a town, so that the old need not leave the surroundings they know well. For those who have to be relieved of the heavier household tasks hostels are suggested, in the same area. Under existing legislation the home making of the aged is a responsibility of no less than three authorities the local councils for small dwellings and hostels, the welfare authorities for the infirm, and the regional hospital boards for those who are sick.

The provision of hostels for single workers is still a matter for investigation in this country, since neither the extent of the need nor the most suitable design has been determined. The committee favour the adoption of standards identical with those for the aged for more or less permanent single workers, but for the young apprentice and the student a reduction of the floor area of the bed sitting room from 140 to 108 sq. feet as a minimum. This seems reasonable, so long as the communal services are not curtailed—and this is the recommendation of the committee. Perhaps the most emphatic, as well as the wisest, proposal for this group is that a full service of communal meals should be provided

> "Apart from the fact that the casual meals service can seldom be run economically, it seems to us that the alternative to a complete meals service too often means a hasty snack eaten in the canteen or improvised hurriedly between the return from the day's work and the evening activities and an inadequate supplement to a light midday lunch. In the case of young people we think the arguments against an arrangement of this sort to be quite conclusive and even amongst older people we feel that the communal service will be preferred to the meal cooked with the restricted facilities that could be provided in a bed sitting room."

In considering the needs of disabled persons the committee show imagination and generosity. The special requirements include ramps in place of steps, wide spaces and doorways to allow a wheeled chair to turn, a larger bathroom than normal, and a second w.c. compartment fitted with holding bars on both sides and a suspended ceiling grip. Many details of equipment have been thought out, especially in relation to ease of movement and avoiding the risks of slipping.

The report as a whole is simple and useful. It is well printed, and is illustrated by good photographs and by plans easily read by the layman.

THE STUDENT'S OUTLOOK

THE medical student learns much and in the end knows little, said Prof. Andrija Stampar of Zagreb, at a discussion held the other day by delegates to the fourth assembly of the World Health Organisation. The present system of education, Dr. Stampar declared, is out of date and in urgent need of reform. It persists in its traditional aim of training physicians to cure individuals of actual disease. But the rapid development of medical science, of public health services, of social medicine, and of social insurance demands a different attitude, and by learning about preventive, social, and constructive medicine the student should be given a healthy outlook on the nation's life and the doctor's rôle in society. Some medical faculties still have no special chairs in these important subjects, and many of them isolate themselves from their public health services. Only when they have rid themselves of this policy of isolation can they become centres of learning that will train doctors more for collective than for individual needs—doctors with more understanding of general health questions that concern people's lives, and their social and economic conditions. Recalling the principle, expressed in the W.H.O. constitution, that governments have a responsibility for the health of their peoples, and that this responsibility can be fulfilled only by the provision of adequate health and social services, Dr. Stampar said that if medical students had become used to this principle during their training we should not have witnessed such desperate opposition by medical men in some countries where national health services have been introduced or have recently been discussed. Is every young doctor (he asked) really convinced that everyone, rich or poor, has an equal right to health ? Is he convinced that his services are not like other services, just another commodity to be sold for money ? The spirit of preventive medicine should permeate the whole of medical education, and not, as at present, be taught in the last year of the curriculum when the student already has settled opinions

THE MEDRESCO HEARING-AID

HEARING AIDS are now so inconspicuous and such a familiar sight—1 in about 200 of our adult population wears one—that they often pass unnoticed The earlier forms of electric amplifier were generally known as "deaf aids," and many of them did indeed advertise the wearer's deafness more than they helped his hearing But in the last fifteen years, thanks largely to the development of miniature wireless valves and small but powerful batteries, easily wearable valve amplified hearing aids have been evolved which give remarkably clear and undistorted reproduction of speech For many deaf people the only remaining objection to the use of an aid has been the price, and it is hardly surprising that, since the National Health Service began to provide (on free loan) and maintain hearing aids for those in need of them, the demand has exceeded the supply To date, more than 120,000 deaf persons in England, Scotland, and Wales have been supplied with a 'Medresco' aid through the Ministry of Health, and almost an equal number are waiting to try one The probable demand was estimated by the Social Survey [1] as being at least 300,000 from among the 1,750,000 hard of hearing persons in this country , and as further improvements in size and performance are made, the proportion of such persons who are prepared to use an aid may well increase So it may be some time before the peak of the demand is reached

As this scheme was something quite new, it was decided that, after it had been working for two years, an attempt should be made to ascertain how far the medresco hearing aids were actually being used The Social Survey undertook this, and their findings are described by Mr Gray and Miss Cartwright on p 1170 These support the anticipations of the Electro Acoustic Committee of the Medical Research Council,[2] who were responsible for the design and development of the medresco aid and who believed that the provision of one type of aid, with even amplification over the whole of the speech frequency range, would meet the needs of all but a few deaf persons They will also quieten the qualms of those who feared that many, if not most, of the aids issued would not be used properly but would be stuffed away in a drawer—a fate that not infrequently overtook the earlier electrical aids Perhaps the most interesting feature of this sample survey is that, with the help of the medresco aid, some 80% of deafened persons over the age of 75 were able to understand all or most of what was said to them , for it has been the general experience that sufferers from senile deafness will tolerate only the purest amplification and that they do not take kindly to electrical aids In fact it will be seen that most of the criticism of users is directed not at the aid itself but at the batteries, which weigh five times as much as the rest of the aid and are more than twice as bulky It is to be hoped that the recent advances made in battery construction and in the amount of current consumed by the valves will enable smaller batteries to be employed without increasing the running costs

The medresco aid has thus come out of this test very well. In six years a hearing aid has been designed, tested, produced, and distributed on a large scale, and studied in action What has not yet been revealed is the fate of those still awaiting trial with an aid At some of the hearing aid centres, where the waiting lists now run into many thousands, it is thought that, at the present rate of issue, five or more years will pass before some deaf people get their turn And, of course, as more aids are issued, so will more of the new aids be needed for replacement of those worn out already, indeed, of every 100 aids issued, about 40 go in replacements Probably most of the 47 hearing aid distributing centres could manage to distribute more aids than they have at present, without reducing the amount of instruction given to each person in the use and maintenance of the aid Such instruction is a very necessary part of the scheme and should not on any account be cut

It is important that the waiting lists should be worked off as quickly as conditions will allow To know that the medresco aid is a success gives no satisfaction to those at the end of the queue , in fact, it only serves to sharpen their impatience Let us hope that enough aids will continue to be produced to enable the existing centres to work at full capacity

THROMBOSIS OF THE INTERNAL CAROTID ARTERY

TRAUMATIC thrombosis of the internal carotid artery was first described by Verneuil [1] in 1872, and its importance as an occasional cause of hemiplegia after head injuries associated with trauma to the neck has been emphasised by Cairns [2] Lately spontaneous thrombosis of the artery has been more often recognised as a cause of the syndrome The introduction by Moniz of carotid arteriography made the diagnosis possible during the patient's life , and it was Moniz who, in 1937, first reported a group of cases [3]

Thrombosis of the internal carotid artery occurs predominantly in men, and the highest incidence seems to be between the ages of 35 and 55 [4] It affects the left side more commonly than the right , and often premonitory symptoms are present for weeks or even months before the fairly sudden onset of severe hemiplegia These warning symptoms are mainly of two types (1) attacks of frontal headache on the side corresponding to the diseased artery, lasting for some hours at a time and usually stopping after hemiplegia has developed , and (2) transient disturbances of function of the cerebral hemisphere supplied by the diseased artery These temporary disturbances consist of hemiparesis or of unilateral sensory symptoms, lasting for anything from a few minutes up to an hour or two , the symptoms clear up completely but recur again and again These transient neurological disturbances tend to come on separately from the attacks of unilateral headache Some patients also have attacks of transient impairment of vision on the affected side, due to retinal ischæmia When hemiplegia finally develops it may come on suddenly , but in some cases the development is "stuttering," with weakness of one leg followed, over the course of days or even weeks, by gradual involvement of the arm and face and of speech Probably the transient premonitory episodes are due to cerebral ischæmia , they may be the result of vasospasm of cerebral arteries due to nerve impulses originating in the diseased wall of the internal carotid artery [5] Clinically the diagnosis is difficult, and Fisher [4] thinks that middle cerebral thrombosis is often diagnosed in these cases. In a large series of necropsies on cases of cerebral vascular disease no instance of thrombosis of the middle cerebral artery was found, though this lesion had commonly been diagnosed during life , unfortunately in this particular series the carotid arteries were not thoroughly examined, and he emphasises how often such an examination is omitted in routine necropsies At times the

diagnosis may be suggested clinically by unilateral absence of carotid pulsation high up in the neck, but a thrombosed carotid artery may become recanalised, and pulsation on both sides some time after an ictus does not rule out the diagnosis At present the diagnosis can be proved with certainty only by demonstrating the block by arteriography

The thrombosis takes place most commonly in the carotid sinus at the beginning of the artery, but it may occur in the part of the artery in the carotid canal In an exhaustive study Hultquist [6] found changes in the brain in only one third of the cases of occlusion of the internal carotid artery below the origin of the ophthalmic artery, and possibly the lesion may sometimes give rise to no symptoms, whether symptoms are produced or not presumably depends on the adequacy of the circulation through the circle of Willis The commonest pathological basis for thrombosis appears to be atheroma in the carotid sinus, and, as Chiari [7] pointed out in 1905, atheroma of the carotid sinus can also be a source of cerebral emboli More rarely the underlying arterial disease is thrombo angiitis obliterans [8] The pathology and clinical characteristics of thrombosis of the internal carotid artery will be further clarified by routine post mortem examination of the whole length of the vessel, by keeping the condition in mind in cases of unexplained hemiplegia, and by arteriographic examination

TAKING THE CURE

To provide an authoritative statement on the place of the spa in modern practice, the British Medical Association appointed a committee under the chairmanship of Lord Horder [9] Its report [10] forms a guide to all the spas in Great Britain, and describes the various forms of treatment obtainable at each. Among the conditions in which the committee believes that spa treatment can be of great value are chronic arthritis of the rheumatoid and degenerative types, muscular, fascial, and fibrositic rheumatism, infections of the urinary tract, pelvic disorders in women, and certain cardiovascular and nervous disorders It also thinks that far more use could be made of the spas for patients recovering from acute illness, whether medical or surgical Anticipating the argument that the physical treatment available at spas could be given equally well at any suitably equipped hospital, it points out that, apart from the concentration of specialised medical facilities, the spas are attractive places with equable climates, and have the amenities of holiday resorts, hence the benefits of physical treatment are supplemented by the important psychological effects of a "complete change" in attractive surroundings with ample opportunity for recreation The committee concludes that the profession in general tends to underestimate the value of spas, and in many ways fails to appreciate the progress made at these centres in recent years Increasing cooperation between the spa hospitals and the universities and teaching hospitals will promote research, permit greater continuity of treatment and standardisation of investigation and follow up, and help the spas to take their proper place in the National Health Service

THE JENNER MEDALLIST

CELEBRATING the centenary of Jenner in 1896 the Epidemiological Society of London founded a medal to be awarded from time to time for distinguished work in epidemiological research or for pre eminence in the prevention and control of epidemic disease The ten recipients have been William Power, A Laveran, Patrick Manson, Shirley Murphy, John McVail, Monckton Copeman, T H C Stevenson, George Buchanan, Arthur Newsholme, and Major Greenwood, and last week a new name was added to the list—that of James Alison Glover In recounting Dr Glover's achievements to a meeting of the section of epidemiology of the Royal Society of Medicine, Dr W H Bradley, the president, singled out three of them as sufficient evidence of "great merit" First was his work on the Prevention of Cerebro-spinal Fever, published by the Medical Research Council in 1920, which led the Army's director of pathology to say that "he has been a good friend to the private soldier" Second was his report to the Ministry of Health in 1924 on the Incidence of Rheumatic Diseases, still cited as basic And third were his Milroy lectures of 1930, including some of his early observations on the streptococcal tonsillitis preceding acute rheumatism "In all this work his concern has been for the sick person," and his qualities have endeared him to an ever increasing circle From 1934 he was the senior medical officer of the Board of Education, and now, ten years after reaching the Civil Service retiring age, ' he still puts in a good day's work at the Ministry of Health, giving wise counsel at the highest level, although his rank is only that of 'temporary' medical officer"

On receiving his medal from Lord Webb Johnson, president of the Royal Society of Medicine, Dr Glover spoke of his father's work as a port medical officer and attributed his own epidemiological contributions to the influence and help of his father and his friends He commended the instruction graven on his medal—veniente occurrite morbo—"run to oppose the coming disease"

WORLD HEALTH ORGANISATION

AT a meeting of the Fourth World Health Assembly on May 16, Germany, Japan, and Spain were admitted to the organisation, this brings the total membership of W H O up to 78 full members and 1 associate member The six countries elected to nominate members to serve on the executive board for the next 12 months were Belgium, Ceylon, Cuba, Greece, Lebanon, and Liberia These members will replace those whose term of office expired this year, other members come from Chile, El Salvador, France, Italy, Pakistan, Philippines, Sweden, Thailand, Turkey, United Kingdom, United States of America, and Venezuela

---

WE have to record the death on May 16 of Surgeon Vice Admiral Sir BASIL HALL, K C B, medical director-general of the Royal Navy from 1934 to 1937

Dr R ST A. HEATHCOTE, F R C.P, formerly professor of pharmacology in the Welsh National School of Medicine, died in London on May 19, aged 62

THE death is also announced of Dr J R C GREENLEES, D S O, headmaster of Loretto from 1926 to 1945 and latterly chairman of the South Eastern Regional Hospital Board for Scotland

The MEDICAL REGISTER for 1951 contains 80,222 names of doctors, an increase of 1082 on last year's total. The new registrations in 1950 numbered 3160, which is 51 more than in 1949, and 32 above the average for the last ten years, but 808 less than in 1948 (the peak year) The Commonwealth list has increased by 491 to 7064, and the foreign list by 86 to 1991 The Register is published for the General Medical Council, 44, Hallam Street, London, W 1, by Constable & Co, Ltd, 10, Orange Street, W C 1 It is in two volumes, and the price is 42*s*

HE MEDRESCO HEARING-AID

ITS USE AND ITS VALUE

GRAY B Sc

ANN CARTWRIGHT B Sc

the Social Survey Division of the Central Office of Information

aring aid service is part of the National Health When the Act came into operation on July 5, was decided that 'Medresco' hearing aids e issued on permanent loan to people who iem The size of the problem was uncertain, igh the Social Survey had estimated (Wilkins t at least 300,000 people would apply for hearing- rate at which they would apply, the extent they would use their aids, and the number ies and repairs that would be needed, was own

hout England and Wales 47 distribution centres been set up at selected hospitals In July, e were only 4 Suitably equipped, the centres d by trained technicians who fit the aids and minor repairs Each serves, on the average, gnostic centres, one of which is generally at hospital as the centre

THE MEDRESCO AIDS

ids are the result of research undertaken by the e on Electro Acoustics (1947), one of three es formed in 1943 after the Ministry of Health d the Medical Research Council (hence the l res co) for advice in dealing with the problem ss

o main types of aid produced are shown in npanying figure The insert type is more than the external, over four fifths of patients ie former type Each aid consists of three s, the receiver or earpiece, the amplifier and ie, and the batteries

e insert type the receiver is clipped on to an ear ch is made from an impression of the patient's ie early days of the service, patients received, as ry measure, one of four sizes of a standard ear his standard fitting is not as comfortable and is it such a good support for the receiver as the y fitted ear mould which is finally issued The e of receiver cannot be worn by patients with or easily irritated ears, a fact they do not always So these patients are given the external type n earphone is held over the ear by a headband rse heavier and more conspicuous

lead connects the earpiece to the amplifier, which, icrophone is contained in a black 'Bakelite' case of the case is a combined switch and volume l at the back there is a clip for fixing the case to the A sunken screw at the back of the case enables ian to set a tone control to give the more suitable equency characteristics A further plastic lead he amplifier to the high and low tension batteries housed in a leather case fitted with an adjustable

ght of a complete aid is 1 lb 11 oz for the insert lb 3 oz for the external type

GETTING AN AID

person's first approach to the service is usually us doctor, who will refer him to a diagnostic ere he is examined by an otologist When it decided that the patient would benefit from o hearing aid, his name is put on a waiting- istribution centre Priority is given to young nd people who need aids for their work

In due course the patient is called to the distribution centre After preliminary testing, he is fitted with the most suitable type of aid, and the tone control is adjusted to the one with which the *patient feels he can best under* stand speech He is then given instruction in the use of the aid, how to turn it on and off, how to adjust the volume, and how to connect up new batteries Often he is given advice about the best way to wear it, and he is usually warned that he may take some time to get used to it, and that he had better not wear it in the street until he is familiar with it

When the aid is issued, the patient is given a booklet containing printed instructions, and space for recording the number *and date of battery issues and of any repairs* He does not need to return to the distribution centre to obtained battery replacements, but chooses a convenient hospital where future issues are made But repairs are always made through the distribution centre

THE AID IN USE

At the end of the first two years the Ministry of Health asked the Social Survey to find out the extent to which patients were using their aids and whether they had any criticisms or suggestions to make about the aids or the service

A random sample of patients aged 16 and over who had been issued with aids before April 30, 1950, were interviewed A two stage sample design was used, the first stage units consisting of 10 distribution centres selected with probability proportionate to the number of

TABLE I—PATIENTS ISSUED WITH MEDRESCO HEARING-AIDS

—	Estimated numbers	All patients issued with aids %	Patients still retaining aids %
Aids returned before this inquiry (August 1950)	4000	5·7*	—
(a) By patients	1800	2·6	
(b) By relatives of dead patients	2200	3·1	
Aids not in use and available for collection	2000	2·9	3·0
(a) From patients	1600	2·3	
(b) From relatives of dead patients	400	0·6	
Patients not using aids but wishing to retain them for further trial	1000	1·4	1·5
Patients claiming to use aids	63 000	90·0	95·5

* Corrected since for some centres these were not included in the sample.

patients issued with aids. This method of selection has been described by Gray and Corlett (1950). The names and addresses of the main sample of 1150 patients were selected from the records of these centres. A further supplementary sample of patients with the less common types of aid was also drawn so that comparisons could be made between patients with the different types of aid. Patients were visited[*] in their homes by trained interviewers who, using a standard questionnaire, recorded the answers to some 70 questions.

The interviewer first confirmed that the patient still had a medresco aid. Returns made by the distribution centres indicated that of the 70,000 adult patients[†] who had been issued with an aid before April 30, 1950, 66,000 or 94% still had an aid at the end of August, 1950, when this inquiry took place. More than half of the 4000 aids which had been returned belonged to patients who had died. It was next ascertained that the patient made some use of the aid and the interviewer collected any aids that were no longer wanted. It is estimated that 2000 aids, that is 3%, would be available for collection in this way, but some of these would be returned eventually in any case. A further 1·5% of the patients admitted that they did not use their aid, but wished to retain it for further trial (table I).

TABLE II—AVERAGE DAILY USE OF THE AID IN THE WEEK BEFORE INTERVIEW

	%	
Aid not used last week		13·7
Used during the interview	6·4	
Not used but in working condition	3·0	
In need of repair or batteries	4·3	
Aid used last week (hours per day)		86·3
less than 2	20·6	
2—less than 4	21·0	
4—less than 6	14·3	
6—less than 8	7·1	
8—less than 10	5·2	
10—less than 15	11·8	
15 or more	6·3	

Thus of the 66,000 adult patients still retaining their aids at the time of the inquiry, 63,000 or 95·5% claimed to use them. It is to these patients, who are later described as the medresco users, that the remainder of the questions were put.

HOW LONG ?

They were asked a series of questions about the use they made of their aid. Some early questions dealt with the different occasions on which they might use the aid and these served to stimulate the memory. They were then asked how many hours they had used their aid on each day during the preceding week. The average daily use for all medresco users was 4·9 hours.

The validity of these estimates was tested by comparing them for consistency with the patients' answers to other questions and with observations made by the interviewer. The tests suggested that the estimates were sound. One such check may be illustrated.

Observed behaviour of patient	*Average daily use (hours)*
Patient was wearing aid when first seen	9·7
Patient immediately put on aid	3·7
Patient put on aid when asked to produce it	3·1
Patient put on aid at a later stage	1·9
Patient did not use aid for the interview	1·6

While the average daily use is 4·9 hours, table II shows there is a considerable variation between patients in their use of the aid.

Nearly 14% of the patients did not use their aid during the week before the interview, but half of these people used their aid for the interview. Answers to other questions suggest that a sixth of this group or about 2% of medresco users make little, if any, use of their aid. At the other end of the scale 18% used their aid for an average of 10 hours a day or more, and at least 6% must have used them throughout each day.

TABLE III—VARIATION IN DAILY USE WITH TYPE OF AID AND AGE OF PATIENT

—	Average daily use (hours)	Proportion of medresco users %
Type of aid		
Insert with individual ear mould	5·9 (5·2)	40·8
Insert with standard ear fitting	4·5	44·4
External (earphone type)	3·1	14·8
Patient's age in years		
16–34	5·3	5·8
35–44	6·1	11·3
45–54	5·4	25·6
55–64	5·1	23·8
65–74	4·0	32·3
75 and over	3·1	11·2
All medresco users	4·9*	100·0

* Standard error 0·2 hours

The amount of use patients make of their aid is affected both by the type of aid and the age of the patient. Insert type aids are used more than the external types, and the insert types fitted with an individual ear mould more than those with only a standard ear fitting. The average daily use made of the aid by different groups of patients, and the proportion of medresco users in these groups are shown in table III.

The average daily use is highest for patients aged 35–44 years and then it decreases with age, reaching its lowest at 3·1 hours for the group aged 75 and over. A third of the medresco users are aged 65 or over, and 11% are 75 or over.

WHAT FOR ?

In addition to the questions about hours of use patients were also asked about the occasions on which they used their aid. Analysis of these answers shows that the external type aids are used less than the insert ones on all occasions.

Of the medresco users who were workers 44% used their aids when working (table IV). Nearly all the patients, 92%, said they used their aids when visited by friends; the next most frequent use, 88%, was when patients visited their friends. More patients listened to the wireless than went to the cinema, 89% compared with

---

[*] Not all the patients were found. For example, 11% of the main sample were not interviewed because they had moved or for other reasons. A comparison of the known characteristics of the whole sample with those of the sample interviewed suggests that the loss had little effect on the sample.

[†] A year later by April 21, 1951, a further 55 000 adult patients had received an aid, making a total of 125 000 patients.

74%, but of the people who did so similar proportions used their aids Of the patients who went shopping 63% used their aid and of those who went out 62% used it in the street The proportion of medresco users who did not go to the cinema at all, 26%, is not higher than has been found in the general population when allowance is made for the age composition of medresco users A slightly lower proportion of medresco users however listened to the wireless than would be expected for a group with this age composition

ABILITY TO HEAR WITH THE AID

The reproduction of speech with maximum intelligibility was the aim of the Committee on Electro Acoustics, who considered that "the greatest inconvenience and loss suffered by deaf people arises from their inability to understand speech" How far this aim has been achieved is shown by patients' answers to the question "When you are wearing the aid and people are talking directly to you, can you understand all that is being said, most of what is being said, or only some of what is being said?" In reply to this question 65% of medresco users claimed to understand all that was being said, 26% could understand most of what was being said, while 9% could understand only some of what was said

Some idea of the relative values of these answers can be obtained by comparing them with tests carried out at one centre on some patients when they were first issued with an aid This test recorded the proportion of words correctly repeated by the patient listening with the aid to test word lists from a speech audiometer corresponding to the level of a moderately loud voice at 3 ft from the person 86 of the patients included in the sample had been tested in this way and the average percentages of words understood by patients giving the three answers were

TABLE IV—SHOWING (A) THE PROPORTION OF PATIENTS WHO ENGAGE IN VARIOUS ACTIVITIES, AND (B) THE PROPORTION OF THESE PATIENTS WHO USE THEIR AID FOR THAT ACTIVITY

Activity	Percentage engaging in activity	Percentage of those engaging in activity who use aid for it
Work	46	44
In the street	98	62
Shopping	83	63
At the cinema	74	85
Listening to radio	89	87
Visiting friends	98	88
Visited by friends	100	93

Understands	*Average of percentage*
All	91
Most	82
Some	73

A 91% average score on this test is not necessarily inconsistent with claims to understand all in the question Since connected speech is more easily understood than discrete word lists and many patients will normally lip read, it is not necessary to hear 100% of the words in conversation to understand it all

The proportion understanding all that was said was higher for patients with insert aids than for those with external aids—70% as compared with 48% It is not possible to say from the evidence of this survey to what extent this difference is due to the aid itself, since patients receiving the two types of aid themselves differ considerably However the difference cannot be accounted for simply by age of patient, although this also affects the patient's ability to understand speech as can be seen from table v

TABLE V—VARIATION IN ABILITY TO UNDERSTAND SPEECH WITH AGE OF PATIENT

Extent to which patient claims to understand speech when wearing aid	All medresco users	Patient's age in years					
		16–34	35–44	45–54	55–64	65–74	75 and over
All	% 65	% 72	% 83	% 72	% 69	% 55	% 43
Most	26	24	14	25	24	31	38
Some	9	4	3	3	7	14	19
Sample (medresco users)	950	50	109	240	236	214	101

The proportion understanding "all" is highest (83%) for patients aged 35–44, but again, as with use of the aid, it reaches it lowest value of 43% for those aged 75 or over

Another factor affecting a patient's ability to understand speech is his type of deafness The type of deafness was obtained from the otologist's report, where available, and has been classified as conductive, perceptive, or mixed The proportion understanding "all," "most," and "some" is given for patients with the three types of deafness in table vi

Three quarters of the patients with conductive deafness claimed to understand all that was said, as compared with only half of those with perceptive deafness

All three factors, the type of aid, the patient's age, and the type of deafness, which have been shown to affect the patient's ability to hear with the aid are associated Thus while over half the patients with external aids are aged 65 or over, less than a third with insert aids are so old Again, elderly patients tend to suffer more from perceptive deafness than younger patients It can be shown, however, that, independently of age, the type of deafness affects a patient's ability to hear More over an appreciable difference still exists between patients with insert and external aids even when age and type of deafness have been standardised

SATISFACTION

With as many as 91% of the patients claiming to understand all or most of what is said when using the aid, it is scarcely surprising to find that the service has been enthusiastically received The main criticism of the aid concerned the weight of the batteries A third of the patients found this troublesome With the case, the batteries weigh about $1\frac{1}{2}$ lb and account for four fifths of the weight of the aid The aid works efficiently with smaller batteries, but the running costs are increased

TABLE VI—VARIATION IN ABILITY TO UNDERSTAND SPEECH WITH TYPE OF DEAFNESS

Extent to which patient claims to understand speech when wearing aid	All medresco users	Type of deafness				
		Conductive	Mixed	Perceptive	No diagnosis	No records available
All	% 65	% 73	% 66	% 53	% 65	% 63
Most	26	23	21	34	29	27
Some	9	4	13	13	6	10
Sample (medresco users)	950	226	99	74	95	456

Towards the end of the interview the patients were ed for their comments on the service generally ly 17% of patients made no approving comment quarter of this 17% indicated that they could not hear properly with the aid and the remainder repeated criticisms made earlier in the interview—mostly about the weight of the batteries 30% of the patients were satisfied with the aid and service, a third of these making some qualification such as "It's a very good aid, but a little bulky—otherwise there is very good reception from it" Just over half the patients, the remaining 53%, made some really enthusiastic comment, a third of these adding some critical remark Typical of the last group is the patient who said "It's only the batteries are rather heavy, otherwise they're marvellous —a very, very good invention—otherwise everything is perfect" Purely enthusiastic comments came from over a third of the patients, such comments as "They are very helpful and beneficial in a hundred and one ways I've no fault to find with it at all."

Such comments and the knowledge that half the patients come from households where the weekly income of the head is £5 a week or less leave little doubt as to the success of and need for the hearing aid service

SUMMARY

Of the patients who had medresco hearing aids at the time of the inquiry, 95 5% claimed to be using them These patients used their aids for an average of 4 9 hours a day 65% of them say that with the aid they can understand all that is said when someone is talking directly to them Both the amount of use made of the aid and the patient's ability to hear are at their maximum for the 35–44 year age-group and then decrease with age of patient Patients with a conductive deafness are more likely to hear well with the aid than those with a perceptive deafness

We wish to acknowledge the help we have received from all concerned with the inquiry We particularly wish to thank Dr Littler and Mr Terence Cawthorne of the Medical Research Council and the technicians of the Bradford Hearing Aid Centre

REGIONAL HOSPITAL BOARDS

THE Minister of Health has made the following appointments to fill vacancies caused by the retirement of a third of the members of the 14 Boards in England and Wales Out of 121 appointments, 90 are reappointments of retiring members, 8 appointments are still outstanding Those now appointed will hold office until March 31, 1954 The names of medical members are shown in bold type

NEWCASTLE REGION

Reappointed A J Best J.P Leslie Bird M.B.E Jack Cohen J.P P S Hancock, O B.E J.P T B Harston, **R. R Jowett,** M.R.C.P Prof **F J Nattrass,** F.R C.P

New Members S Hills A. C R Punnett one appointment outstanding

LEEDS REGION

Reappointed S Clayton Fryers Mrs N Fienburgh, J C Hunter Mrs I Barbara Shaw Alderman R E Smith, **Donald Watson,** F R C.S

New members **R. A. Murray Scott,** M D, **P J Moir,** M C F R.C.S (until March 31, 1952) one appointment outstanding

SHEFFIELD REGION

Reappointed Mrs. Gladys Buxton, J.P Prof **E. F Finch,** F.R C.S, **J L. A. Grout,** M.C, F.F.R, W B Jarvis, O B.E, J.P, Lieut Colonel N Gervis Pearson, D.S O, M.C, G H. Round, J.P W Scholey, J.P

New members **H. Temple Tate,** M.B.E F.R C O G, Mrs Clark, John Roberts (until March 31, 1952), one appointment outstanding

EAST ANGLIAN REGION

Reappointed Prof **A Leslie Banks,** F R C.P, **R W Butler,** F R C.S, Mrs N R Dow, C Dudson R B Keefe Miss C McCall, Sir Cecil Oakes, W H York.

New member Prof T G P Spear

NORTH-EAST METROPOLITAN REGION

Reappointed H. W Butler M.P, **George Graham,** F.R C.P **Robert Poots,** M.B, **R. W Reid,** F.R.C.S, Alderman C H Simmons, J.P W V Wakefield, Mrs A. Hollingsworth

NORTH WEST METROPOLITAN REGION

Reappointed F J Ballard, G B Jeffery D.SC, F.R.S, Miss **Katharine C Lloyd-Williams,** M.D Alderman H. R Neate, A. C de Rothschild.

New members **V Zachary Cope,** F.R.C.S, A. E Ward, Frederick Lawrence, Kenneth Robinson, M.P one appointment outstanding

SOUTH EAST METROPOLITAN REGION

Reappointed **C W Brook,** M.R.C.S The Hon Ruth Buckley, Sir **William Kelsey Fry,** C B.E., M.C, F.R C.S, F D.S R C S, S C Harris, J.P **J B Hunter,** C.B.E, M.C, F.R C.S, **W G Masefield,** M.R C S

New members The Hon. Mrs. Sylvia Fletcher Moulton O.B.E J.P Alderman J C Maclean, E J Mount (until March 31 1953).

SOUTH WEST METROPOLITAN REGION

Reappointed E F Crundwell A. G Linfield, C B.E **David Stark Murray,** M.B Richard Sargood J.P

New members **G S Todd,** C V O, O.B.E F.R.C.P, Alderman Mrs. V King Colonel C Chieveley Williams, O.B.E Alderman W A. J Case, M.B.E., J.P, **H. E Harding,** F.R C S

OXFORD REGION

Reappointed Miss **Janet Vaughan,** F.R C P (reappointed chairman) H A. Goddard, Sir David Lindsay Keir, LL.D, W R Robins Sir George Schuster K C.S.I K.C.M.G, C B E, M C

New member J E S Clapp one appointment outstanding

SOUTH WESTERN REGION

Reappointed Prof **R. J Brocklehurst,** D M, Victor Collins O B E, **C J Fuller,** F.R.C.P, Alderman Mrs. J Marshall G G Gilmour White, O B.E M.A., J.P Prof. **R. Milnes Walker,** F.R C.S

New members W N Scott Lady Katherine McNeille, Mrs D E. King Alderman F A. Parrish, C B.E J.P (until March 31 1953)

WELSH REGION

Reappointed Captain W J Canton, H T Edwards Alderman Thomas Evans William Evans, J.P, Mrs K. W Jones Roberts J.P Thomas McDonald J T Morrison, Prof **R. M. F Picken,** M.B **J H. O Roberts,** M.D J.P **Roy Thomas,** F.R.C.S Alderman the Rev W D Thomas

BIRMINGHAM REGION

Reappointed Alderman A. F Bradbeer Major L E Bury, O.B.E J.P Alderman W T Bowen Alderman W L Dingley, V W Grosvenor, J.P (appointed chairman) C O Langley, **J H. Sheldon,** F.R.C.P Prof **A. P Thomson,** M.C F R.C P **A. J Watson,** F.R.C.S

MANCHESTER REGION

Reappointed F Bussy, W A. Davies, C.B.E J.P, **R. L. Newell,** F.R C.S Prof **Harry Platt,** F.R C.S

New members C C Sumner, Sir James Lythgoe, Councillor A M Watson, S H Hampson, M B E, A C C Robertson, J.P (until March 31, 1952), two appointments outstanding

LIVERPOOL REGION

Reappointed Councillor E A Ashton, Alderman N Birch, J.P, Prof **W M Frazer,** O.B.E, M D, **J T Morrison,** O B E, F R C S, J Taylor, J.P

New members Mrs Annie Cain, J.P, one appointment outstanding

GENERAL PRACTICE IN SCOTLAND

IN its second report the Scottish Medical Practices Committee remarks that even in areas where the need for additional doctors seems to be clearly established there has been no influx of new practitioners This, says the committee, may be due to two causes (1) that even with a fixed annual payment a doctor setting up in practice will normally face a period of financial stringency unless he takes over the nucleus of a practice, and (2) that he may experience difficulty in finding either a living place or premises from which to conduct his practice (In one area the executive council's first, second, and third choice for an advertised vacancy all failed to find accommodation) "It follows, therefore, that some practical steps may require to be taken by Executive Councils and the medical profession if there is to be a more satisfactory distribution of general practitioners In the Committee's view the most satisfactory way of increasing medical strength is by the formation of medical partnerships"

The committee remarks that since the first report was published,[1] responsibility for selecting doctors to fill vacancies has been placed with executive councils, in consultation with local medical committees, and any appeal lies to the Medical Practices Committee Furthermore, the concurrence of the Medical Practices Committee is now necessary before a proposal by an executive council not to advertise a vacancy may be made effective, and the committee may, where it deems this desirable, require an executive council to advertise a vacancy

Discussing the remote areas, the committee observes that applications to practise are few, the response to advertisements of vacancies is poor, and applicants are mostly fairly young This may be due to two factors (*a*) reluctance to take a step which might seem to lead to isolation, and (*b*) the difficulty experienced by younger men in establishing themselves in general practice, and their desire—if not need—to seize any opportunity to do so The committee asks that executive councils and local medical committees, when filling vacancies in less remote areas, should give special consideration to applications from doctors in remote areas, so as to provide an avenue of outlet to those who have worked for some time in isolation and apart from normal contact with professional colleagues

The number of doctors providing general medical services was 2409 at July 1, 1950, compared with 2419 at Dec 1, 1949

Executive council areas, or part thereof, where the need for additional doctors appears to the committee to be established, are as follow

County of Dunbarton	Dumbarton, Alexandria/Renton
County of Fife	Buckhaven, Methil, and East Wemyss, Dunfermline, Rosyth, Inverkeithing, Charlestown, Cowdenbeath, Lochgelly, Lochore, Glencraig, Kelty, Cardenden, Crossgates
Galloway	Stranraer
County of Lanark	Airdrie, Bellshill
Lothians and Peebles	Musselburgh, Bathgate
County of Orkney	Kirkwall
County of Renfrew	Paisley, Johnstone, Port Glasgow
County of Ross and Cromarty	Barvas
Counties of Stirling and Clackmannan	Bannockburn, Falkirk, Grangemouth.

Addition to the number of doctors would be desirable in the following executive council areas, or part thereof

Counties of Aberdeen and Kincardine	Laurencekirk, Ellon
County of Angus	Forfar
County of Caithness	Wick
County of Dumfries	Annan, Dumfries
County of Dunbarton	Clydebank
Galloway	Whithorn
County of Inverness	Inverness
Lothians and Peebles	Armadale, Bo'ness, Haddington, Tranent
Counties of Perth and Kinross	Blairgowrie, Stanley and Bankfoot
County of Ross and Cromarty	Ullapool
Counties of Roxburgh, Berwick, and Selkirk	Galashiels
Counties of Stirling and Clackmannan	Alloa, Kilsyth, Stirling
County of Zetland	Lerwick and the Island of Bressay

GENERAL MEDICAL COUNCIL

OPENING the 181st session of the council last Tuesday, Prof DAVID CAMPBELL, the president, spoke with regret of the death of Sir Leonard Parsons, F R S, a member of the council, and of Dr Thomas Fraser, a former member, also of Prof J A Nixon, who during the late war was inspector of qualifying examinations in medicine.

The President recalled that, under the Medical Act, 1950, the council's legal name [formerly the General Council of Medical Education and Registration of the United Kingdom] was now the General Medical Council During the present session members would be invited to make regulations under this Act which (subject to approval by the Privy Council and to Parliamentary scrutiny) would fix the period of service as house-officer before a doctor could be fully registered, and to make further regulations determining how the whole period was to be divided between medicine and surgery, how far time spent in the practice of midwifery might be counted as time spent in one of the other two main subjects, and the maximum time spent in a health centre which might similarly be reckoned towards the completion of the periods spent in medicine or surgery The new Medical Disciplinary Committee had already made the Medical Disciplinary Committee (Procedure) Rules, 1951, which came into operation on April 18 The first meeting of the Penal Cases Committee, now a statutory body, was held on April 24, and the first disciplinary cases referred to it by the Medical Disciplinary Committee would be heard on May 24 Except for the remnant of old disciplinary cases reserved to the council, the transfer of cases to the Medical Disciplinary Committee was complete, and on April 14 this committee also became responsible for dealing with applications for restoration to the Register after disciplinary erasure Also under the Act, the normal fee for registration had been increased from £5 to 11 guineas, and an addendum to the *British Pharmacopœia* had been published and would come into force on Sept 1

Finally, the President spoke appreciatively of the work of Mr Michael Heseltine, C B, the registrar, who was shortly to be succeeded by Mr W K Pyke Lees Mr Heseltine's eighteen years in this appointment had included the difficult war years in which "there continued to flow from his eager and able brain and pen important memoranda written in fine, clear, and cogent language, and a joy to read" Latterly Mr Heseltine had done great work on the Medical Bill, now the Medical Act, 1950 Mr Heseltine was to continue to work on the historical, educational, and legal aspects of the council's activities

The Wider World

A CITY OF THE MIDDLE WEST

FROM AN AMERICAN CORRESPONDENT

THE city lies within 200 miles of Chicago, complicated nexus for four north central States thriving richly on agriculture and industry Its over 100,000 inhabitants are matched by an equal number in the neighbouring small cities, towns, villages, and farms Many machine tool shops turn out a variety of products, from electric motors to automotive pistons, the international giants of heavy industry are well represented elsewhere in the State

In 1940, in a population somewhat smaller than it is now, more than 90% were native born whites, 4% foreign-born whites, and 2 5% Negroes, with a scattering of a dozen Asiatics Few cities of comparable size boast so homogeneous a population, the large majority stemming from German stock whose descendants scarcely know German or even the derivation of their names One fifth are Catholics, and an equal proportion highly conservative Lutherans, the remainder comprising the numerous Protestant sects whose churches help swell the city's total to more than 120

Except for the "downtown" business and shopping areas and the factory foci at irregularly distributed points, architecture is mainly confined to single family frame houses, painted white and set back from the tree lined streets like minor monuments on the expanse of green lawn Two thirds are occupant owned, the majority costing less than $10,000 to reproduce at current prices The owners themselves do much of the necessary painting, plumbing, electrical wiring, and upkeep A motor car is taken for granted, only the lack of one causes comment The adult male's wage now probably averages $65–70 weekly before deduction of the national withholding tax on income, although the State's per caput income is only median, the city's ranks among the nation's highest

Marriage takes place 3–5 years earlier than in large cities, and children are so much the normal life pattern that the decision to have children, how many, or at what time, rarely comes up for discussion Compared with the standards set by outstanding schools in the East, the educational level is low, but not lower than the national average The percentage of young people entering college from local secondary schools is reportedly more than double the national figure Conformity in most things is the rule, no one wants to be conspicuous for divergent opinions or activities A recent analysis of a small population sample revealed a greater than average degree of submissiveness among adults The cultural level approximates that of other non university cities of its size, raised somewhat above these by an excellent free public library supported by its own taxation independent of other governmental agencies, a semi professional symphony orchestra and a competent amateur theatre Veterans societies' club houses serve as social centres for their members Sports competitions, chiefly football and basketball (the latter played both by high school teams and by professional athletes) provide the chief recreation

Two hundred physicians and four hospitals with a total capacity of 800 beds represent medicine One of the four hospitals plans the early erection of a substitute with double the old capacity Another is under the Veterans Administration, but because of shortages in medical and nursing personnel only 50% of its 200 beds are filled Of the two hundred physicians, fewer than a quarter profess to be specialists, the rest are general practitioners Many are graduates of the State university medical school, which is yet to be included among the nation s best Of these, a large proportion have had only a single year's internship in a local hospital, entailing the expected concomitant disadvantages of such limited experience

General practice is what the term implies, in fact, the usual office sign assigns the doctor a broad field—physician and surgeon No hospital attempts to restrict the doctor in his practice, nor are the results of his labours ever genuinely reviewed or criticised, despite the efforts of the American College of Surgeons The little existing criticism derives from a small lay minority transferred by business firms or coming by choice from large Eastern cities. The indigenous population protests little *Vis mediatrix naturæ* is often mistaken for professional skill, especially when aided and abetted by copious doses of antibiotics, one succeeding another until the gamut is run

Office calls are $2–3, home visits $3–5, depending on the hour of the day A few physicians see 150–200 persons a day, apart from hospital surgical patients, 60–70 patients a day is not uncommon, while doctors more recently embarked on practice see 25–30 daily Appendicectomy brings not less than $150, children's tonsillectomy $65–75—fees ordinarily reserved for specialists in large cities Anæsthesia administration at $25 by a general practitioner is extra, and the specialist anæsthetists usually receive no more Ironically, appendicectomy (scarred appendices heavily outnumber the acutely inflamed) brings twice the price of an obstetrical delivery with its prepartum and postpartum care *Medical Economics* has periodically surveyed medical incomes, and finds the highest averages in cities of 100,000–200,000, this city is no exception

The Negro community dwells in a slum area where fewer than a score of houses have been built in forty years Limited as well in employment opportunities by the forces inherent elsewhere in the country, it is served by several Negro physicians in the ratio of 1 to each 2500 persons These physicians, in general practice and professionally comparable with their white colleagues, number some whites in their practices as white physicians number a few Negroes

Employment among all groups is universal, collections are good The general prosperity boosts the tax funds made available by local authorities for the care of the indigent and disabled, and, consequently, the physician's income as well The local medical society yearly contracts with the authorities, for a stated sum, to care for the indigent and disabled as if they were private paying patients Each month office and home calls and surgical procedures are prorated and charged against the fund, which for at least ten years has been large enough, with the indigent patients few enough, to return the doctor a private patient fee

Such is the background against which layman and physician view "socialised medicine" A further description of the community may clarify the local attitude a high percentage of conservative Catholics and Lutherans, a numerically greater orientation toward the Republican than the Democratic party, and virtually everyone in both parties on the right wing, a nearly universal reading of the local newspaper (a less skilful but even more conservative version of the *Chicago Tribune*, which itself outsells all other out of town dailies), a practically non-existent readership of liberal dailies or weeklies, and perhaps less reading of serious books or periodicals than the excellence of the local library warrants, little foreign travel except for the several thousand young men who saw service abroad in the late war and who hold no very flattering opinion of "foreigners"

The local medical body actively supports A M.A policies but with considerable reluctance to foot the high costs of implementing those policies In part this reluctance may be attributed to a general unwillingness to spend money, physicians are said to be poor contributors to local philanthropies, one possible source of the resentment of the laity against the elevated medical income

(Incidentally, income tax officers in the United States review a higher proportion of physicians' returns than of any other group) Any contemplated change in the status quo is a threat to income and to established patterns , and the doctor and, in turn, the layman are suspicious of any innovation as a Socialist (read "Communist ") plot to overthrow the American Way of Life "Socialised medicine in Germany led to Hitler" , "the National Health Service has been established with American dollars" , "Do you want to have to stand in line to see your doctor ? "

Physicians in this part of the country have pioneered in the establishment of an Association of American Physicians and Surgeons, one of whose activities is a competitive essay contest among secondary school students, to whom both material and references are furnished by the association Essay subjects concern the superiority of the status quo to other systems of medical practice, with special emphasis on the former's unique American aspects At one time the association included in its constitution a clause to become effective should "government medicine" be instituted by law This provided that wherever 75% of physicians voted to stay out of the scheme, these would then boycott those doctors who decided to enter The realisation that the association would be liable to prosecution under a charge of "conspiracy in restraint of trade" prompted cooler heads to delete the clause

As it now functions there is no pressure to alter the established patterns of medical practice, and this for several reasons (1) the indigent receives the same standard of care as does his employed brother, who can in addition find relief in Blue Cross, Blue Shield, and other forms of reduced cost hospital and medical care insurance , (2) the doctor is paid for all services regardless of the patient's economic status , and (3) the present trend in the United States is deeply conservative, a trend consistent with basic local inclinations

Public Health

Public-health Salaries

In December, 1950, the Industrial Court gave its award on the salaries of assistant medical officers, of senior medical officers, and of medical officers of health [1] The salary scales for deputy medical officers, for divisional or area medical officers, and for officers holding mixed appointments were referred back by the court, to be determined by joint negotiation, and in the event of failure to reach agreement either party was at liberty to report such failure to the court Agreement was not reached, and on Jan 15, 1951, the secretary of the staff side of Medical Whitley Committee C made formal application to the court to determine the matters in dispute The court heard the parties on these matters at three sittings during April and issued its award on May 7 Copies may be had from H M Stationery Office

The management side, "reinforced in their view that doctors employed by local authorities have, as regards salaries and conditions of service, an affinity with other local authority employees rather than medical practitioners," proposed nine scales which they are discussing in other negotiating machinery, of which the top seven (with a minimum salary of £1050 in the third and a maximum of £2000 in the ninth scale) would be appropriate to the grades of medical officer in question Local authorities would place these officers into a scale they consider appropriate to the post and the person occupying it, with a refinement of the scale in the case of mixed appointments

For deputy medical officers of health the staff side claimed a commencing salary which is 75% of the minimum of the scale selected by the employing authority for the medical officer of health within the appropriate range as awarded for medical officers of health by the Industrial Court, plus annual increments which depended on population and aggregated to £200 minimum and £300 maximum The court have awarded a commencing salary of two thirds of the minimum adopted by the employing authority for its medical officer of health, and annual increments equivalent to those of the medical officer of health The following table, for a few selected populations, illustrates the claim and the award

Population not exceeding	*Staff side claim salary*	*Award*
100,000	£1162 10s -£1387 10s	£1033-£1233
250 000	£1462 10s -£1687 10s	£1300-£1500
600 000	£1725-£2025	£1533-£1800
600 000 +	At discretion	At discretion

Increments claimed and awarded aggregate £250-£300 for different populations

Divisional or area medical officers receive an award based on the salary previously awarded to senior medical officers (£1250-£50-£1650) , where the population of the division does not exceed 150,000, 250,000, and 400 000 there is added to these scales £50, £150, and £250 respectively Where the population of the division exceeds 400,000, the addition is at discretion For this class of officer, the award is £100 less than the claim (The position of divisional or area medical officers whose responsibilities do not cover the whole range of health services—including the school medical service—is still being considered by Committee C)

For mixed appointments the court award the appropriate proportion of the salary of the county post (as assistant medical officer, divisional, or area medical officer) and the appropriate proportion of the salary of the county district medical officer of health, plus the appropriate proportion of £100

This, like all other such awards, is a compromise It was as natural for the public health service to insist on its affinities with other branches of medicine as it was inevitable that the local authorities should emphasise that in matters of salary they could not ignore the effect of awards to one profession on other professions For the time being the issue is settled , but that does not imply that all discontents are removed or all anomalies rectified On the contrary, the whole time divisional medical officer, regarding the salary of his colleague the district medical officer, may well have cause to think that the anomalies are intensified

The newly qualified man, weighing his choice of a career, will naturally compare the financial rewards of the consultant service, of general practice, and of public health The next year or two will shed light on the numbers seeking a postgraduate public health qualification and competing for posts Among other things, that light will illuminate the profession's opinion of the attractiveness or otherwise of the new salary scales

The Registrar-General's Review

It may be that the period 1946-47, covered in the latest review from the Registrar General,[1] will prove more remarkable for the establishment of national systems of morbidity recording, for use both in hospital and home, than for the mortality experience of these years An international working party produced an agreed system of classification of disease , pilot record schemes were started in four teaching hospitals , and the Survey of Sickness by sampling and house to house visits was well established

Some at least of the preliminary results of the survey are now to hand to supplement the data already published [2]

[1] The Registrar General's Statistical Review of England and Wales for the two years 1946-47 Text vol I Medical London H M Stationery Office 1951 Pp 325 6s 6d

[2] Sickness in the Population of England and Wales in 1944-47 Studies in Medical and Population Subjects no - London 1949

e long spell of exceptionally cold weather in the first ree months of 1947, for example, produced an increase the number of severe rather than minor illnesses

The first fruits of morbidity recording should not, wever, obscure the vital facts of mortality, particularly this review is wisely insistent on the need for careful spection of the detail of statistical tabulation Thus ile for most purposes a simple measure of the risk to fant life is given by the ratio of the number of deaths der 1 year of age in 1947 to the number of births gistered in that year, the use of such a value in 1946 d 1947 would have suggested that in 1947 there had en a check to the satisfactory decline in infant mortality recent years A more accurate rate, based on the timated number of births to which the infant deaths 1947 could be related, showed that in fact the 1947 fant mortality experience was better than in 1946 he acid test of inter regional comparisons, however, owed that there could be no grounds for complacency ot only were death rates in the North and in Wales % above the rate in South East England but the gap as widening quickly Similar caution is needed in terpreting such summary measures of mortality as age andardised death rates A detailed study of age x-specific death rates shows that though mortality general declined between 1946 and 1947, there were itical changes in the experience of certain groups of the opulation Among men, for example, despite the fact at the crude death rate was the same in 1947 as it was 1946, mortality increased in every age group over 45 ome of this was due to the continued increase in deaths om cancer of lung and coronary and myocardial disease omen, particularly if they have taken the elementary recaution of being married, fare much better, as always, cardiac mortality is an index of resilience, women were uch less affected by the cumulative effects of war than ere their weaker brothers In tuberculosis, too, milar factors operate The "generation" effects f childhood environment in determining tuberculosis ortality in later life do not appear among women over 0, but their menfolk show in their relatively adverse xperience the cumulant effects of stress during the two ars and the selective thinning of their ranks by the eaths of the fittest of their generation in the first world ar

Diphtheria Immunisation

The Ministry of Health has expressed concern at the lling off in the numbers of babies and children immunised against diphtheria In England and Wales more han 140,000 fewer babies were protected in 1950 than n 1949, the figures fell by 23,000 during the first half f the year, and by 117,000 in the second half

Since the immunisation campaign began in 1941 over million babies and children have been immunised Diphtheria deaths have fallen from a pre-war average of 2800 per annum to 49 last year—a new low record. Cases have declined from 55,000 per annum to 980—also a new low record

Mortality in 1950

The Registrar General announces[1] that in England and Wales during 1950 the death rate (provisional) for respiratory tuberculosis was 321 per 1,000,000 population, and the rate for other forms of tuberculosis 43 per 1,000,000 The death-rate from cancer was 1991 per 1,000,000 The maternal mortality, based on deaths primarily classed to diseases of pregnancy, childbirth, and the puerperal state as arranged in the Manual of the International List (6th revision) was as follows

No	*Cause*	*Mortality per 1000 live and still births*
651	Abortion with sepsis	0.09
650 652	Other abortion	0.05
640 649 670 678	Complication of pregnancy and delivery	0.54
681	Sepsis of childbirth and puerperium	0.03
680 682-689	Other complications of the puerperium	0.15

In England Now

A Running Commentary by Peripatetic Correspondents

THE plea that the labourer is worthy of his hire is cynically regarded as the conventional assertion of the overpaid. There must be few recorded examples of anyone admitting that he was paid more than he deserved, whereas protestations to the contrary are almost universal. All the obvious anomalies can no doubt be explained on the principle of supply and demand The buffoon who receives an astronomical salary must be worth it to his employers, who, as they are accustomed to point out, are not in business for their health So many factors enter into the question of remuneration—the pleasantness or otherwise of the occupation, the possession of some monopoly, whether a natural gift or a laboriously acquired technique, the preference of some for kudos rather than financial gain, and so on.

I often think that literature is a serious claimant for the world's poorest recognition There are, it is true, the plums for the giants in this as in all professions. Conan Doyle claimed as much as seven and sixpence or ten shillings a word when in his heyday, and O Henry, I am sure, had he possessed any commercial sense could have asked (and would have received) double that rate And this in the days when money was really money Among medical works there are, I understand, a sprinkling of best-sellers that ensure a steady if modest trickle into the exchequer, but many writers would be content with the glow of authorship plus the cost of ink and paper

A few years ago, tempted by the glamour of association with the learned, the eminent, even the titled, I accepted an invitation to participate in a textbook symposium From time to time I received encouraging reports of the book's success, and last week a balance-sheet showing the profit to date which had been divided among the contributors in proportion to the length of their contributions and enclosing as my share, a cheque for 15*s* 10*d* Deducting income and super tax—I am still, but probably for the last year of my life, in the super class—I reckon this works out at a penny for 30 words or, say, three lines It would be difficult to represent this on a time-work basis, but, even excluding the elements of study, technical knowledge and experience, I think sixpence an hour would not be far from the mark So assuming an eight-hour working day, even with my modest requirements, it is barely a living wage

* * *

Whether you look on the rabbit as a useful supplement to the meat ration or as an unmitigated pest, you cannot deny that it is a remarkable animal Their young, for instance, instead of having the disproportionately large head, spindly legs, and general ugliness characteristic of most animals in their early stages, are perfect miniatures of the adult rabbit Then a doe is said to give the richest milk of all mammals, though so far my extensive search of the literature has not unearthed any supporting evidence The calorie value of milk seems to vary inversely with the size of the animal producing it

—	*Composition of milk (%)*							*Calorie value per 100 ml.*
	Water	*Protein*	*Fat*	*Lactose*	*Ash*	*Calcium*	*Phosphorus*	
Human	87.5	1.0	4.4	7.0	0.21	0.35	0.01	70
Cow	87.2	3.5	3.7	4.9	0.72	0.12	0.09	74
Ewe	82.7	5.5	6.4	4.7	0.92	0.20	0.17	109
Goat	86.5	3.6	4.0	5.1	0.81	0.13	0.10	79
Mare	89.0	2.7	1.6	6.1	0.51	—	—	54
Sow	82.0	6.2	6.8	—	0.96	0.25	0.15	113
Bitch	75.4	11.2	9.6	3.1	0.73	—	—	163

These figures may not be so remarkable when one remembers the different rates of growth of the youngsters If you want to rear baby rabbits by hand, you should fortify cow's milk and even proprietary baby foods with cream and sugar But bringing up rabbits is an art not easily acquired, though some children, including my daughter have a gift for it Her technique (personal communication) is to give them very frequent feeds with numerous remedies and which completely stopped as soon as hyoscine was given

Statistical evidence for the value of any drug in this condition is impossible to obtain, but it seems clear that this drug is of the greatest value, and that it should always be the first to be tried as soon as breath holding or carbon dioxide have failed

Ruislip Middlesex J D LAYCOCK

PUBLICITY IN CANCER

SIR,—Professor Russ has added to his many public services by raising again (March 24) the urgent importance of publicity in cancer, and has quoted as examples two of the most important cancers of all—breast and cervix They are important not only because of the number of cases but because the cure rate is very high (of the order of 70%) if treatment is given in the early stages

Mr Malcolm Donaldson (April 28) has supplemented the plea by stressing the importance and value of educational campaigns among the laity, for which he has himself long been a devoted worker There is by now a considerable amount of experience of such propaganda efforts, especially in America and some Continental countries, no one, I think, will deny that they carry a definite risk of increasing cancerphobia in susceptible individuals, yet many of those who have the requisite experience are satisfied that the public benefit achieved outweighs the disadvantages The medical profession should be acutely aware by now of the dangers of the wrong type of "health" propaganda, and doctors know full well how dangerous a little knowledge can be The mother whose thoughts fly to poliomyelitis each time her child is off colour, the hypochondriacs who plague our consulting rooms and outpatient clinics—these are to some extent victims of the wrong kind of propaganda Yet what is the alternative? A public that is beginning to be educated will insist on a certain minimum of knowledge, and if it cannot get it from wholesome sources will undoubtedly get it elsewhere However much we may be irritated at times by the undigested 'information" picked up by our patients we should realise that it is, on the whole, a healthy sign of the times, and that in the long run a higher level of general education and awareness is our best ally in the campaign against disease

Cancer is, I think, a special case It seems to be an inevitable accompaniment of civilisation, and the more effective our hygienic and anti infective measures, with consequent increased longevity, the greater will its relative incidence become Civilised communities must develop a cancer consciousness, which is not the same thing as cancerphobia, it means an awareness of the high curability rate of most cancers and of the importance of early diagnosis Mr Donaldson sets great store by popular lectures and can point to a large personal experience, one doctor has told me, however, that after a good deal of such lecturing he gave it up as relatively ineffective in comparison with the effort needed Two methods suggest themselves as particularly suitable owing to their high publicity value—the radio and screen There have been at least two recent programmes, one on television and the other on sound only, dealing with cancer, and the speakers, I am told, emphasised the importance of early diagnosis in forthright words I think there should be more programmes to the same end, to spread the net as widely as possible Broadcasts in the Woman's Hour series would also be invaluable, and they should be repeated, with suitable background variations, at not too long intervals Short documentary type films shown at cinemas alongside the usual programmes would also reach a large public

Another line of approach is the periodic medical examination The theoretical ideal of a thorough overhaul for most of the population at regular intervals is clearly impracticable for a long time to come, but a breast-and-pelvis examination of all women between 40 and 70 is much more practicable At a rough estimate, for every 1500 women examined annually we could expect to pick up 2 cancers of breast and 1 of cervix—1 of these two most important and curable of cancers for every 500 women In addition, about the same number of skin cancers would be noted, though these are less important for our purpose since the mortality from skin cancer (apart from melanocarcinoma) is now very low A very occasional case of cancer of rectum, tongue, vulva, or other easily accessible site would also be added Women of 40–70 form about 18% of the populace—say 1 in 6, a general practitioner's list of 3000 patients therefore might include some 500 for examination If 10 were examined each week they would all be seen within the year, and the time taken would be relatively short

I would like to see a pilot experiment on these lines. Moreover there is another advantage in such a personal examination—subtler than conventional propaganda but in the long run perhaps more important than anything else—I mean the genuinely educational value of the process It would tend to make the subjects "prophylaxis minded" and impress on them the value of early detection The presence of the doctor would lead many to declare their secret fears and hearten them to come regularly for routine examination—at least there is British and American evidence that this is what tends to happen These people would also be the best advocates among their own families and friends

Medical man power and harsh economics may make even this limited programme difficult to realise, though as between these two major lines of approach—mass propaganda and individual examination—I should much prefer the latter Is it really too much to ask?

PSYCHOSOMATIC APPROACH TO PULMONARY TUBERCULOSIS

SIR,—May I be allowed a few observations in connection with Dr George Day's article of May 12, which I have read with great interest

Dr Day wonders whether tuberculosis, cancer, and other destructive diseases should not sometimes be regarded as "psychotic conversions" This is a view which has developed over many years in my own mind, and I am wont to use the term "psychotic conversion" in a colloquial way It appears to me that the same character which enables a process to surmount the somatic barrier manifests itself in the mental sphere in a quasi psychotic way

About two years ago I visited the Mount Sinai Hospital in New York There a psychosomatic approach is cultivated on a large scale, in that to each specialty is attached at least one psychiatrist (in most cases a psychoanalyst) and they number more than fifty in all When I spoke to some of them, expounding this view, they were greatly interested and told me that they had of late seemed to be moving in exactly the same direction.

I am not familiar with Dr Day's statement that it is "notorious that, if one succeeds in depriving an asthmatic of his asthma, there is a chance of his becoming schizophrenic", but he may well have had in mind an experience of which I told him

> In this case a young married woman lost severe and frequent asthmatic attacks which had been occurring since early youth as a result of a few months of psychotherapeutic treatment However, after a holiday interruption I found her in a paranoid state with delusions centred upon myself She was unable to continue, relapsed and went back to her ordinary physician for treatment by injections as before A year later I saw her again in a sanatorium where she had returned to the care of a

physician to whom she had long formed a very strong attachment She had been heavily sedated and was now in a psychotic state very reminiscent of schizophrenia, overlaid by gross toxic hallucinations She had to be transferred to a private mental nursing home, since she was too restless and difficult to be kept in the physician's nursing home She recognised me at once, and had good contact with me despite her deranged state of mind She made a good recovery, could soon be allowed home, and had, on balance, probably benefited by this "reconversion" of her asthma

This case illustrates very well the exchange of a psychosomatic syndrome for a psychotic state It appears to me also interesting that this patient's condition did not correspond to any of the known "textbook" psychoses and was, in my opinion, not a schizophrenic episode

These observations lend colour to Dr Day's view that extreme caution and judgment are required in the approach to somatic disorders from a psychological point of view

London W 1 S H FOULKES

PROPRIETARY PREPARATIONS

SIR,—The Cohen Committee recommended that doctors should avoid prescribing proprietary medicines advertised direct to the public The most recent reaction to this is the packing of two proprietary products of identical composition, by either the same manufacturer or associated companies, under different names, one being advertised to the public and the other to the medical profession

The solution to the question of prescribing proprietary preparations is not easy There are many objections to the list of equivalents included in the *National Formulary* before the war, mainly because some were not exact equivalents The only practicable way, to my mind is to produce a list, suitably cross referenced, giving the formulæ (adjusted by calculation to a common basis) of both proprietary products and similar preparations in the *B.P C*, &c In producing this, regard should be given to the limited time at the disposal of doctors, and it should preferably be produced in similar size to the *N.F*

Newcastle upon Tyne A FORSTER

ORGANIC HYPERINSULINISM TREATED WITH ALLOXAN

SIR,—In his letter of April 28 Dr Mårtensson has ably outlined a number of provocative points arising from the article of Feb 24 by Dr Gilchrist and myself.

Though we cannot be sure that other blood constituents did not contribute to the enormous citric acid level, it would appear from other factors—namely, the high fatty acid and pyruvic acid levels—that there existed a stepped up Krebs's cycle with damming up at the citric acid stage, and probably occasioned by the altered metabolism on the part of the hepatoma—akin to enzymic fluoro acetate derangement at least in effect Indeed, it is well known that citric acids have been found to be increased in hepatitis and cirrhosis

Positive proof of hyperinsulinism cannot be adduced, and from this aspect the title of our article might have been better chosen However, there were factors present which pointed to hyperinsulinism Evidence for a normal though fast moving, anaerobic or phosphorylation cycle of glucose metabolism was found in (*a*) the sharp fall repeatedly seen in the blood glucose level following the peak elevation on oral administration of large doses of this sugar, (*b*) the normal creatinine excretion, and (*c*) the high blood pyruvic acid levels, though these probably also reflected some increased alpha ketoglutarate

In the pancreas there was presumptive histological evidence for hyperinsulinism Islet tissue was exceedingly abundant frequently up to 15–20 islands were seen in one low power (× 75 field)

The maximum and minimum diameters of 71 islets, measured in succession and without selection by traversing completely on a projecting microscope one small section taken from the tail of the pancreas, gave a mean size of 215 × 130 μ. Of these 71 islets 38 had maximum diameters in excess of 200 μ, 28 had greatest diameters of 250 μ or more, 13 exceeded 300 μ in this measurement, while 7 were in excess of 350 μ and 4 passed 400 μ The largest islet seen measured 660 × 360 μ 50 islands from two normal organs of cases in the same age-decade, and measured similarly, gave average greatest and least diameters of 117 × 84 μ. Of these only 4 exceeded 200 μ in maximum diameter, and none had a dimension greater than 240 μ

Further evidence for the large size of the islets was found in the total cell counts in performing which very small islands having less than 15 cells were omitted in the controls as well as in the case in question The cells were counted in the plane of one section 24 islets from the case under discussion gave a mean cellular content of 336 cells per unit—a figure which does not include the giant islet mentioned 25 islets from three control normal organs gave a mean content of 152 cells per island These comparative figures are more impressive when it is realised that a large number of beta-cells had been completely destroyed by the alloxan.

The islet hyperplasia and probable hyperinsulinism may be interpreted as in some way secondary to deranged metabolism occasioned by the hepatic carcinoma—e g, evoked by some accumulated member or members of the tricarboxylic acid cycle, or by the formation of abnormal metabolites on the part of the tumour It is not assumed that the clinical hypoglycæmia was due only to this, indeed, it is very probable that the hepatic neoplasm was the greater culprit

PREVENTION OF TUBERCULOSIS IN YOUNG PEOPLE

SIR,—Last week's article by Dr Anderson and his colleagues is evidently based on a very careful survey, and we should do well to ponder the findings

In one sentence, however, the authors conclude that our methods of detecting tubercle bacilli in the sputum of patients are poor, on the ground that there were an unexpectedly high number of conversions among apparently negative cases I suspect that in many of these cases the conversions were due to contact with an unexamined, unknown positive case among the contacts, such as a friend or neighbour If this is so the original negative patients and the converted contacts were the contacts of, and infected by, undetected sources common to both parties

URETHRAL CARUNCLES

SIR —I appreciated the comments (April 28) of Mr Mills and of Dr Taylor and Professor McLaren on my short article of April 14 I have no objection to the name "caruncle" but deplore a symptom masquerading as an entity

Mr Mills states " the exquisite tenderness of pedunculated fragments of granulation tissue are lesions whose existence can hardly be doubted On the contrary, they are the classical group and very much subject to doubt I should certainly like to hear more about specific instances of exquisitely sensitive and painful masses with narrow pedicles situated on an otherwise normal urethral mucosa in the absence of present or past infection of the urinary tract Most of the so called "caruncles" are not particularly tender, though I have seen one or two conditioned iatrically or by mirror contemplation, as a Yogi his navel In these the agony was manifested before the probe had made contact If, as Mr Mills asserts, the mother country still boasts of a few of the veteran type of caruncle, I must reduce my negative generalisation—always hard to prove—to a close approximation In any case I am sure he will agree that a long range battle of the "caruncles" would be unprofitable and inconclusive

My chief purpose in writing at all was to discredit the "caruncle" as a cause of dysuria, and put the blame firmly where it belongs on infection or the after effects of infection in the urinary or genital tract The impostor must not continue to divert attention from the real nigger in the woodpile Not all doctors can be expected to be au fait with all the nuances of innocent and guilty "caruncles," if any of the latter exist

> A primrose by a river's brim
> A yellow primrose was to him,
> And it was nothing more

SURGERY OF MITRAL DISEASE

SIR,—In your annotation of April 21, you point to the need for the right word for the new operation, which neither "valvulotomy" nor "commissurotomy" quite describes I would like to propose the following names

(1) cuspidotomy (derived from *cuspis*),

(2) (Tri)glochinotomy (see Quain's *Elements of Anatomy* 11 ed, vol 4, part 3, p 43),

(3) annulotomy ("the annulus fibrosus, a ring of fibrous tissue at the atrio ventricular junction, to which the bases of the cusps are attached," *Ibid*) I believe that the third name would be the most correct

Budapest Hungary LAJOS LÉVY

SPECIALISATION IN TEACHING

SIR,—From time to time correspondence centres around the matter of specialisation in teaching in the undergraduate sections of the medical schools In view of the more usual absence of comment by the teachers it may be as well that a few notes be recorded in reply to Dr Richards's remarks in your issue of May 12, especially in view of his obvious awareness of particular situations in and around teaching departments I would suggest, however, that Dr Richards is too sweeping when he says that the average undergraduate does not "come under the influence of a teacher who would describe himself simply as a doctor, able to help him fit his specialised learning into its proper perspective"

A not inconsiderable number of clinical teachers are well versed in the art and science of general practice, and in fact are giving increasing attention to those essentials in method and outlook which will engender, as early as possible, in the mind of the undergraduate, the notion that for "every practical reason the patient's body is indivisible", and, moreover, the essential linkings of the physical trends of the individual, whether a child or an adult, to the social, occupational, environmental, temperamental, and psychological aspects, is constantly brought forward in clinical discussion and demonstration It must not be assumed that the teachers are necessarily mentally isolated from the world of general practice On the contrary, many of them have had years of experience with general practitioners and domiciliary consulting practice, and in some cases a personal experience of general practice itself As a result of that a clinical teacher becomes a great asset in the department and has an approach to the undergraduate scheme hardly obtainable otherwise, and he does not fail to create a realistic and effective manner in his teaching methods He comes to realise that vacillation and vague diffuseness is to be avoided, that general practice is not a compendium of specialties but a carefully planned synthesis The suitable training of new general practitioners is something much more than "a more modest goal"—it must be calculated in terms of the best beginning to a life's study of human nature The general practitioner is the field worker and observer of morbidities

Departments which carry one or two men as "passengers" (using Dr Richards's definition) are never at a disadvantage The "passenger" may distinctly enlighten the scene when "knowledge comes, but wisdom lingers" No medical school should be without them The busy general physician or general surgeon, who hardly ever has time to put pen to paper, may be a veritable golden treasury in his anecdotal chats with the students about the doctors, patients, homes, and problem situations which arise almost daily in the round of very useful but possibly unobtrusive activity Thank heavens there are all sorts of personalities to be found in our medical schools The strength of the schools lies a great deal in this mixture of personalities, varying between the departmental specialist who loses his mind in a "heart case" to the general man who can gain the mind of the patient to his own heart and in doing so sees all round the "case and its whole situation" It is common for teachers in medical schools to have a phasic interest in some special aspects, but this may in no way impair the continuity of an all round enthusiasm

I hope that there is no absolute truth in the idea that "in the clinical and the scientific departments of medical schools the selection of staff on their research ability has ensured that they are manned entirely by specialists." I doubt if a medical school could survive on such unbalanced teaching personnel. Appointment should rightly be associated with ability within the humanities, and not infrequently anyway the "specialist" is basically a sound general physician or surgeon who has, after many years, tended to canalise his interests somewhat But not unwisely, in his dealing with undergraduates, he lets his mind flow in fields of knowledge, advice, and guidance well outside his so called specialty Specialism, worked properly into the tangle of medical education, can be a golden thread in the students' build up Over departmentalism must be avoided, it must definitely appear a reality to the student that what the administration may regard as tidy departmental isolation has, in fact, no effective separation either in teaching or the system of graduating examination In other words "specialisation" need not entail retreat from the central theme of Medicine Most undergraduates are potently attracted to those teachers who will engage them in a discussional attitude to the wide and open fields of medical and paramedical matters

It is certainly unwise for Dr Richards to assume that, whilst "the community supports universities primarily that they may teach all faculty members are principally interested in something other than teaching" A dualism of interest—teaching and research—is the proper province of the medical school No antagonisms or incompatibilities need arise out of these conditions Of course, general practitioners (by which I presume is meant domiciliary practitioners) can and must be increasingly brought into the picture They are already so in some medical schools, and their influence will grow We all know that training on sick people in hospitals is only one aspect of medical activity Training in the diagnosis of health and the ways of maintenance of health in the home, the factory, the school, or the street are other aspects worthy of teaching skill, and, in further answer to Dr Richards, there are, therefore, not a few senior people who in their teaching feel sure they are doing something of quite definite value to society I have no doubt that we can rest assured that many of us who have responsibilities in the appointment of teachers in medical schools do not fail to weigh all the merits of the candidates, and we do not put personality, general y, wide perspective, and an understanding of the graduates' real demands out of very high priority ese considerations

Obituary

CHRISTOPHER GRAHAM MILLER
B.M. Oxfd

ristopher Miller, who died at Bradford on April 30, e age of 24 received his early education at Clifton ge, and in 1944 he went up, as a scholar, to Balliol ge, Oxford, later graduating with second-class urs For his clinical studies he proceeded to the lon Hospital, from which he qualified last year he time of his death Miller was in his first hospital ntment, and a senior colleague tells of the cientiousness and kindness which he brought to his as house-surgeon. His clinical notes, on which orked far into the night, were of a quality unusual in teaching hospitals, he felt keenly responsible is patients, and seldom left the hospital A friend knew Miller at Oxford writes

His first interest in medicine was humane and he combined this a deep Christian feeling He was one of an important p of students who kept his College together during the ult war years, his main special activity was in the ol Boys Club He was a delightful person to know vas shy, and his reserve took a little breaking through— most penetrating and wittiest remarks might be made st to himself—but this quietness was never uncomfortable he had many friends I felt that he would be an influence ood medicine and good life '

Notes and News

THE CASE FOR A MINISTER OF SOCIAL SERVICES

THE Minister of Health, divested of responsibility for housing, is no longer a member of the Cabinet, and earlier this year we suggested [1] that it was unlikely that the remodelled Ministry, now small, isolated, and junior, would have much bargaining strength either at the level of Cabinet committee decisions or in its relations with the Treasury. The argument for appointing, or identifying, a member of the Cabinet responsible for the health and other social services has lately been expressed by Mr Aneurin Bevan, erstwhile Minister of Health and subsequently Minister of Labour. Such a member, he reasons,[2] should be at least as influential as the Chancellor of the Exchequer. "some way must be found to protect the social services from annual raids by the Chancellor of the Exchequer, whoever he may be. It is all the more necessary to do this because a modern Chancellor must take in review the whole field of social income and expenditure in order to assess the deflationary or inflationary influences at work. The expenditure on the social services is a standing invitation to a harassed Chancellor in search of reduced expenditure, or increased revenue, or both."

CHANGES IN THE POISONS LIST

THE following changes are made in the poisons list and rules under the Poisons List (Amendment) Order, 1951 (S.I. 1951 no. 721), and the Poisons Rules, 1951 (S.I. 1951 no. 722), which come into operation on June 1.

Part 1 of the poisons list

(*a*) The item anti histamine substances is amended to include chlorcyclizine and promethazine.

(*b*) The following substances are added: gallamine, organic compounds of mercury which contain a methyl (CH_3) group directly linked to the mercury atom, and paramethadione.

Part 2 of the poisons list

The entry 'organic compounds of mercury' is amended to read "organic compounds of mercury except compounds which contain a methyl (CH_3) group directly linked to the mercury atom."

First schedule to the principal rules

(*a*) The item anti histamine substances is amended to include chlorcyclizine and promethazine.

(*b*) The following substances are added: gallamine and para methadione.

(*c*) At the end of the item commencing with the word 'Amino alcohols' the following words are added: 'and except procaine when contained in any preparation of which a substance to which the Penicillin Act 1947 applies is an ingredient or part.'

Group 2 of the third schedule to the principal rules

(*a*) In the first column to the item commencing 'anti histamine substances' there is added chlorcyclizine and promethazine.

(*b*) To the second column of the item "Phenols" there is added "para tertiary amyl phenol."

Fourth schedule to the principal rules

(*a*) The item anti histamine substances is amended to include chlorcyclizine and promethazine.

(*b*) The following substances are added: gallamine and para methadione.

Ninth schedule to the principal rules

In the note to this schedule after the words 'organic compounds of mercury' there are added the words 'except compounds which contain a methyl (CH_3) group directly linked to the mercury atom.'

SCULPTURE AT MENTAL HOSPITAL

THE value of art in the therapeutic programme of a hospital for nervous and mental disorders is now widely recognised. Two recent books, *Art versus Illness*, by Adrian Hill, and *Art and Regeneration*, by Maria Petrie, have helped to explain and popularise the principles involved. Most hospitals have concentrated on the graphic arts, and many have availed themselves of the services of the Council for Music in Hospitals. Sculpture has had less attention, and the exhibition at the Basingstoke Museum, by patients from Park Prewett Hospital, will therefore be of interest. This exhibition was opened on May 24 by Dr W. S. Maclay, senior commissioner of the Board of Control, and will remain open until June 9. Park Prewett was fortunate in obtaining the services, as instructor, of Eric Benfield, F.R.S.A., author of *Purbeck Shop* and a sculptor of some distinction himself. He has not forced his own ideas on patients, but has encouraged them to express their own fancies and imaginations, and he is always ready to advise on technique. None of the exhibitors had had any previous experience in sculpture, and it was a pleasant surprise to discover the latent talent. The 42 exhibits, in Bath stone, by sixteen patients, display a variety of subjects—some rather conventional, others such as "Snake woman" and "Tree of Life," original and imaginative. The bizarre is less in evidence than is usual in exhibitions of graphic work from mental hospitals, but there is something of the "primitive" in many of the exhibits. As is true of graphic creations, the schizophrenic group of patients are the most generous contributors: of the sixteen, twelve are classified amongst the schizophrenias—be it active or latent, or schizoid personality.

HEALTH SERVICE ESTIMATES 1951-52

IN our correspondence columns on April 21 (p. 912) Dr Harold Leeson asked what was the "other staff" whose wages and salaries, according to the hospital estimates, came to £21,144,000. In a written answer in the House of Commons on May 11 the Minister of Health explained that this entry relates to "a great variety of staff who cannot be classified in a small number of groups but about one half of the amount is for 'domestic staff' and another quarter for 'porters' using those terms in a broad sense."

ROYAL CANCER HOSPITAL CENTENARY

THE centenary of the Royal Cancer Hospital, London, was celebrated last week by a reception at the hospital and demonstrations in the Chester Beatty Research Institute.

At the centenary dinner on May 17, Sir Edward Cripps, the chairman, read a message from the King congratulating the hospital on its great work during the 100 years of its existence and wishing it continued success. Sir Henry Dale, O.M., F.R.S., recalled how Dr William Marsden founded the hospital at Hollywood Road, West Brompton, after his wife died from cancer. The hospital, which later moved to its present site in Fulham Road, was the first to receive patients without letters of recommendation from subscribers and also the first to deal solely with cancer. Its founders had little encouragement from others, who did not altogether approve of a charitable hospital for one disease, but they did what they could with courageous enterprise, and their efforts were reflected in the magnificent record of the hospital in the years that followed. Sir Henry thought it apt that the centenary should fall at the time when, in the Festival, the country was holding a public audit of its achievements during the last century. Unhappily we had not seen that peaceful coöperation which the exhibition of 1851 was meant to inaugurate, and many of the scientific discoveries since made had been used for destruction, but it was comforting to reflect that many of the scientific advances made during the urgency of war had been adapted for humane use. The Royal Cancer Hospital, he concluded, had much to be proud of in the past and great hopes for the future. Lord Horder, consulting physician to the hospital, said that he spoke as the oldest member of the staff of the hospital, and he recalled some of the personalities with whom he had been associated during his work there. The special hospitals had made immense contributions to medical knowledge despite the fact that their foundation had been discouraged. He went on to ask for a change in the hospital's name, and suggested that it be called the "Royal Chelsea Hospital," with the subtitle "for the treatment of cancer and allied diseases." Proposing The Guests, Mr Oliver Lyttelton, president of the hospital, paid tribute to the work of the medical profession. He was glad, he said, that research institutions had not come under the control of the National Health Service, for it was essential that research should be completely independent of Government control. With departmental control there was a tendency to uniformity, and with uniformity often came mediocrity: in no profession was uniformity more inappropriate than in medicine. Mr Hilary Marquand, the Minister of Health, said that the Royal Cancer Hospital was an institution of which the country and Commonwealth could be proud. The change of ownership that came with the National Health Service had brought no change in the purpose of the hospital's work. He was glad to hear that a film was being prepared which would bring to the attention of the public the dangers of cancer: the purpose of this film was not to terrify but to reassure and enable early diagnosis to be made. Cancer was the deadliest of foes and a challenge to all those concerned in fighting it, and the hospital could be proud of its 100 years spent in attempting to overcome the disease.

At the Chester Beatty Research Institute the demonstrations illustrated the contributions of the various sciences to cancer research. In cytology the effect of radiation and various chemicals on cell structure was shown, and methods of cell study by means of ultraviolet micrography and microspectrography, phase contrast microscopy and cinemicrography, and electron micrography were exhibited Other demonstrations included the preservation of chicken tumour viruses by freeze drying electrophoretic diffusion studies, the biochemistry of tumours and of carcinogenic and radiomimetic substances, cytogenetic studies of chemical mutagens, spectroscopy of biologically important substances and the application of spectroscopy to cancer research, and methods of separation of commercial dyestuffs into fractions for chemical identification and biological testing in relation to occupational bladder tumours A selection of specimens illustrated the earlier history of experimental carcinogenesis, and in the institute library a selection of original papers from the institute was shown

ONE OF THE BETTER EXHIBITIONS

A NEAT pictorial epitome of progress in public health may now be seen at the London School of Hygiene and Tropical Medicine One of the study groups which are formed by the students in the D P H course has collected perhaps a couple of hundred photographs, drawings, and other exhibits, and has arranged them cleverly to show how past evils have been tackled and what has still to be done From cheering illustrations of improvement in the physical environment of children, we pass to a review of housing and town planning, an exposition of the Five Freedoms portraits of the founders of modern hygiene, and sections on tropical medicine and nutrition, including some telling facts and pictures from the Gambia, where Prof B S Platt s department has a field unit at work. Small but of a high standard, this exhibition is a fitting contribution by the school to the Festival of Britain The students responsible are Dr C G Burgess, Dr A. G Farr, Dr E H Lamb, and Dr D H Mackay—helped occasionally one suspects, by Prof James Mackintosh and other members of the school council, in whose name Dr Andrew Topping the dean, last week welcomed Mr Hilary Marquand the Minister of Health, as the first visitor

NATIONAL MORBIDITY INQUIRY

IN 1948 the Ministry of Health arranged for the collection of data about inpatients from selected hospitals for central analysis in accordance with the 1948 International List of Diseases, Injuries, and Causes of Death. From this limited trial it is clear according to the Ministry, that wider collection of data would yield results of value for the compilation of national morbidity statistics, the development of research, and the general planning of the National Health Service For these purposes it is not necessary to collect information on all hospital patients, and the Minister is therefore considering the introduction of a system of sampling The Ministry states (R H B [51]45) that it will shortly ask hospitals that have been taking part in the limited trial to comment on the transcription form now in use The aim is to introduce a revised form at the beginning of 1952, and to ask all hospitals to complete this form in respect of a sample of their patients Meanwhile hospitals taking part in the trial are asked to continue to do so on the present basis

RUSSIAN LONGEVITY

OLD comrades never die—to judge by a recent Russian survey on longevity [1] which showed that there are more than 30 000 people in the Soviet Union who are more than 100 years old. Neither do they fade away for Vassily Sergeivich Tishkin, now in his 145th year, worked 256 days on his collective farm last year, and on election day this winter walked to the voting booth himself while Makhmud Eivazov, who is 142 is a deputy of his local soviet, works on a collective farm, and regularly bathes in a mountain stream. Whereas in capitalist countries there are few examples of such persistence, conditions in the Soviet Union are stated to favour long life, and the Kharkov Institute of Biology is to publish a book called ' U S S R —Country of Longevity ' Which draws from the *New York Times* [2] the rejoinder that length of life in the Soviet Union is apt to be governed by capricious laws

---

Biochemica e Terapia Sperimentale and *Patologia Comparata della Tuberculosi* are now being published as a single journal entitled *Notiziario dell'Istituto Vaccinogeno Antitubercolare*, of which the first issue is dated January–March, 1951

University of Cambridge

In a congregation on May 12, the degree of bachelor of medicine and surgery was conferred on B E L Thompson

University of London

Prof P B Medawar, D SC, F.R.S, has been appointed to the Jodrell chair of zoology and comparative anatomy at University College from Oct 1 Dr Medawar has held the Mason chair of zoology in the University of Birmingham since 1947

University of Sheffield

Dr H E Harding, senior lecturer in pathology, has been appointed reader in pathology

University of Manchester

Dr C Fraser Brockington has been appointed professor of social and preventive medicine in succession to Dr Andrew Topping Dr Brockington will take up his duties in Manchester in August

Dr Brockington studied medicine at Cambridge and Guy's qualifying in 1927 In 1928 he obtained the D P H and two years later the degree of M D After holding resident appointments at the Hospital for Sick Children Great Ormond Street and at Brighton Infectious Diseases Hospital and Sanatorium in 1930 he became assistant county medical officer for Worcestershire After some years in private practice he returned to a public health appointment in West Sussex in 1936, going to Warwickshire as deputy medical officer of health in 1938 and becoming county M O H in 1942 In 1946 he received his present appointment as county M O H for the West Riding of Yorkshire and he has been lecturer in preventive medicine in the University of Leeds since 1948 He has published papers on epidemiology nutrition and social medicine

Royal College of Surgeons of England

At a meeting of the council on May 10, with Sir Cecil Wakeley, the president, in the chair, Mr R L Holt and Mr G Qvist were admitted to the court of examiners Mr A. H Harkness, (London Skin Hospital), Mr I W Magill (Westminster) Mr A O Parker (Cardiff), Surgeon Captain R W Higgins, R N, and Prof T Nicol (King s College) were admitted to the fellowship The Walker prize was presented to Prof Alexander Haddow (Chester Beatty Research Institute), and the Begley prize to Mr G L Howe (Middlesex)

Diplomas of membership were granted to those named in our report of the comitia of the Royal College of Physicians (*Lancet* May 5 1951 p 1023) The D O H was also granted to A J Watson, and the D P H to H L Wolfe

Royal College of Surgeons of Edinburgh

At a meeting on May 17 with Mr W Quarry Wood, the president in the chair, the following were admitted fellows

H A Beagley Anwar El Masry W T Gibbs R R Gilfillan P D Goatcher J M D Hay T A H Hurrell R M Jackson W H McGillivray I M. Maciver Murarimohan Mukherji, T J Noonan Gurdial Singh D B Skewes R G Townsend L W van Blerck J A M White

West London Medico-chirurgical Society

This society s annual banquet is to be held on Wednesday, June 6 at the Royal College of Surgeons, at 8 P M

Lebanon Hospital for Mental and Nervous Disorders

Addressing last Monday the annual meeting, in London, of the Lebanon Hospital for Mental and Nervous Disorders, Asfuriyeh the Earl of Feversham, the president, said that the hospital had done good work in a country where the need was great He welcomed the matron of the hospital, Miss Mary Morrissey who had just arrived from the Lebanon, and finally he proposed that Sir William Houstoun Boswall, formerly British Minister in Beirut, be elected a vice president Mr H Lyn Harris, chairman of the London committee, said that 1950 had been a year of great progress The hospital had been partly rebuilt new sanitary and medical equipment had been installed, and many improvements for the welfare of patients and staff had been made The chairman went on to speak of the energy and enthusiasm that Dr W M Ford Robertson, the medical director, had put into his work since taking up his post in February, 1950 The report of the medical director was read by Dr J C Sawle Thomas, chairman of the medical committee, who said that advances had been made in the medical teaching at the hospital under the new director who held the post of associate professor of psychiatry at the American University of Beirut It was hoped to start a neurosis centre at the Lebanon Hospital as soon as possible, and other schemes included the provision of scholarships to enable the best student nurses to come to Great Britain for further training

[2] *Ibid* April 28 1951 p 6

Royal Sanitary Institute

Mr G R Oake, chairman of the Interdepartmental Committee on the Inspection of Meat, will discuss this committee's report in the Benjamin Ward Richardson lecture, to be delivered at the institute on Wednesday, June 20, at 2 30 P M

West London Hospital Medical School

Dr Leonard Colebrook, F R S, will deliver the fourth Alex Simpson Smith lecture on Tuesday, June 12 at 8 30 P M, at 11, Chandos Street, W 1 Dr Colebrook is to speak on Outstanding Problems of Burns and Scalds Application for tickets should be made to the dean of the school, London, W 6

French Congress of Stomatology

This congress will be held in Paris at the Fondation Eastman from Oct 8 to 13 under the chairmanship of Dr Rene Vincent The organisers would especially welcome papers from British doctors who are interested in dental problems Further particulars may be had from Dr Friez, secretary general of the congress, 12, rue Notre Dame des Champs, Paris, 6e

Charges for Dentures and Spectacles

These charges, under the National Health Service Act, 1951, came into force last Monday, May 21 (see *Lancet*, April 28, 1951, p 967) The charges are not applicable to patients who on that date were already undergoing dental treatment involving dentures, or to those for whom glasses were already on order

Medicine and the Festival

The Festival scientific meetings organised jointly by the British Medical Association and the Royal Society of Medicine will be opened on Monday, June 4, at the Royal Society of Medicine, 1, Wimpole Street, London, W 1 The opening ceremony will be performed by the Earl of Athlone chancellor of the University of London, accompanied by Princess Alice, chancellor of the University of the West Indies

Conference on Electron Microscopy

The electron microscopy group of the Institute of Physics is holding a conference at St Andrews on June 19 and 20 The speakers will include Dr M S C Birkbeck of the Chester Beatty Research Institute, Mr C E Challice, and Dr A S McFarlane of the National Institute for Medical Research Further particulars may be had from the hon secretary of the group, Mr F W Cuckow, M SC F INST P, Chester Beatty Research Institute, Royal Cancer Hospital, London, S W 3

Award of George Medal

The George Medal has been awarded to Squadron Leader T C L Brown M B

On the night of Dec 20 1950, Squadron Leader Brown was travelling as a passenger on a training flight from Singapore when a propeller blade broke loose The blade cut through the fuselage and seriously injured the co pilot, and within a few seconds the faulty engine fell out of the aircraft Without regard to his own safety Squadron Leader Brown administered medical aid to the injured man with whom he stayed until the aircraft crashed He himself was seriously injured and there is no doubt,' says the citation that he consciously risked his life in order to save that of the injured officer'

British Cardiac Society

The thirtieth annual meeting of this society was held in Glasgow on May 10, under the chairmanship of Dr J H Wright A discussion on heart disorders of pulmonary origin was opened by Prof J McMichael, Dr A J Thomas, and Dr Paul Wood Short communications, arranged by the secretary, Dr K Shirley Smith, included papers on vector cardiography, clinical and cardiographic aspects of cardiac infarction, and electrokymography colour films illustrating movements of the valves of the heart and diaphragmatic flutter were shown

Donor Eyes

The Southern Ophthalmological Society visited the corneo plastic unit at the Queen Victoria Hospital, East Grinstead, on May 5, for a demonstration by Mr B W Rycroft of the operative technique of lamellar corneal grafting and dacryocystorhinostomy He also showed cases illustrating optical, therapeutic and cosmetic grafts, and he emphasised the urgent need for donor eyes He invited the cooperation of the society, and of all ophthalmic surgeons, in the provision of donor material A box for transport of the eye under suitable conditions would be sent in time for any case if notification were received by the unit in advance

Société Nationale Française de Gastro-enterologie

The dates of this society's next meeting have been changed from June 16 and 17 to June 15 and 16

Malaya's Need for Doctors

At the request of the Colonial Office the Ministry of Health has notified hospitals of the need for more doctors in Malaya. The Ministry's circular (R H B [51]44) remarks "The Government regard as an essential step in the re establishment of law and order there, that full civil administration and social services should be introduced in each area as it becomes ready"

The 1949–50 issue of the collected papers of the Middlesex Hospital Medical School has now been published

The title of the U S Public Health Service's monthly journal, hitherto known as the *Industrial Hygiene Newsletter*, has been changed to *Industrial Health Monthly*

CORRIGENDUM *Plasmosan in the Prevention and Treatment of Shock*—The qualifications of Dr F J R Stoneham, joint author of this article last week, are L R C P, M R C S, D A

PHYSICAL EXERCISE*

ITS CLINICAL ASSOCIATIONS

SIR ADOLPHE ABRAHAMS
O.B.E., M.A., M.D. Camb., F.R.C.P.
CONSULTING PHYSICIAN TO WESTMINSTER HOSPITAL

The Pathology of Exercise

The ill effects that are with more or less justification attributable to exercise fall under two heads: those in which a grave lesion or a fatal collapse occurs during the performance, and those in which, as the result of repeated maximal or submaximal efforts, deterioration of some vital structure, especially the heart, is produced. To these may be added a number of minor disturbances, which are less serious but which act as a handicap and encourage advice in the hope of prevention.

When death occurs during the performance of physical exertion, two features are as a rule conspicuous: the triviality of the effort, or the discovery of some long pre-existing lesion which had never been suspected.

When no adequate cause for death is found post mortem, the presumption is the occurrence of an intense vagal inhibition in a strongly predisposed subject, especially of the more or less hypothetical thymico-lymphatic type. In this, narrowness of the aorta is a most consistent characteristic (Millar and Ross 1942). In the majority of deaths that occur during exercise, necropsy reveals disease of such magnitude as to make it almost unbelievable that the sufferer could have survived at all with moderate activity, still less the capacity for outstanding athleticism.

Jokl (1940a) has collected 67 examples comprehended under the category of acute fatal non-traumatic collapse during work and sport. The conditions discovered at necropsy included coronary arterial disease, aneurysm of the aorta, cerebral arterial disease, rupture of an aneurysm in a tuberculous cavity, and rupture of the aorta. One of his most striking examples may be described in detail.

During a strenuous game, the captain of the Transvaal rugby team, 32 years of age, collapsed and died. His previous athletic ability had earned him the title of the Iron Man of South African Football.

At necropsy the heart weighed 17 ounces. In the wall of the left ventricle were fibrotic patches. The coronaries exhibited widespread atheroma, the left branch being narrowed in three places. The aorta was extremely thin and soft. The left kidney was small with advanced hydronephrosis; the right kidney, the size of a walnut, was cystically degenerated. The thymus was conspicuously enlarged.

Young subjects may be afflicted with grave congenital lesions through which their survival is seriously jeopardised, yet remain completely free from distress until some precipitating factor—apparently most trivial—results in fatal collapse.

Lumsden (1946) records a remarkable case:

An Indian seaman, aged 25, reported to his medical officer with the complaint of dizziness. He had had six years' naval service with a clean medical history, and examination revealed no abnormal physical signs; the cardiac rate was 66 and rhythm regular. Having volunteered to demonstrate his disability by taking a short run of twenty yards, he fell unconscious and died immediately. Post-mortem examination showed an enormously dilated right atrium, a patent foramen ovale, and advanced atheroma of the ascending aorta which was thickened, hard, and inelastic.

The two following cases came under my own observation:

A soldier, aged 31, with three years service was engaged in light physical training at 7.15 A.M. After a few minutes he collapsed and he was dead at 7.40 A.M. Necropsy showed slight coronary atheroma. The right ventricle weighed 19 ounces, the myocardium being almost completely replaced by fat. The wall of the left ventricle was thickened, and although of normal appearance, showed an early stage of the same patchy necrosis.

A young woman collapsed and died whilst skipping shortly after a meal. Necropsy revealed congenital absence of the left branch of the coronary artery. Presumably the gastro-coronary reflex caused a critical reduction of oxygen supply to a myocardium with insufficient reserve.

Many circumstances may produce a fatal vagal inhibition during very mild exercise. An unusual cause of death is reported by Lande et al. (1942):

During a football match a player sustained a slight collision and fell dead. It was discovered post mortem that a hydatid cyst on the inferior surface of the right lobe of the liver had ruptured into the abdominal cavity. Fatal allergic shock occurred from sudden intraperitoneal injection of its contents.

In 1884, a historical catastrophic lesion resulting directly from violent exercise occurred in a medical student:

Whilst representing Cambridge against Oxford in the 120 yards hurdles race, an event that he won in first-class time, he collapsed with severe pain in the back. Œdema of the legs and scrotum rapidly developed, with slowly progressing dilatation of the superficial veins of the abdominal wall and a high degree of albuminuria, all of which persisted for the remainder of his life—i.e., 25 years—during which he practised as a leading obstetrician. At necropsy the whole of the inferior vena cava below the hepatic veins was found to be converted into a flat impervious ribbon.

He had followed the not unusual practice of holding his breath for the whole or the greater part of the race—a kind of converse Valsalva phenomenon. Extreme distension of the inferior vena cava had led to localised rupture of the intima followed by forcible extravasation into the walls of the vein whilst exertion was still in progress—a dissecting varix in fact, homologous with a dissecting aneurysm of the aorta.

Sprinters are accustomed to hold their breath during their intense effort, in the belief that fixation of the thorax is an aid to locomotion. Hence provocation of the above lesion has been present on tens of thousands of occasions. Yet I can trace only one similar example of thrombophlebitis (Foster and Brouwer 1941):

The patient was a girl of 20, giving a gymnastic performance, and in her case the lesion was far less severe. Œdema of the legs and dilatation of the veins of the abdominal wall gradually disappeared, and after 11 months she was able to return, with very little inconvenience, to her occupation of games mistress.

This girl had undergone tonsillectomy shortly before her accident, and it is suggested that a temporary bacteriæmia was responsible for a weakening of the vessel wall, which yielded to the strain. The obstruction must have progressed slowly enough to permit the development of an adequate collateral circulation. In the case of the medical student, it is reasonable to postulate a predisposition to thrombosis. Shattock (1913), to whom we are indebted for a description of the necropsy, ascertained that a brother died with œdema of the lower part of the body following pressure on the inferior vena cava, and another brother from embolism of the pulmonary artery following thrombosis of a femoral vein. It is not unlikely that modern hæmatological investigations would have revealed a familial exalted coagulability of the blood—the reverse of hæmophilia.

The sudden sharp rise in blood pressure that occurs in violent exercise may be responsible for rupture of a congenital aneurysm which has provided no previous evidence of its existence.

EXERCISE AND INFECTION

The danger of taking exercise whilst suffering from a pyrexial illness has often been emphasised, and although the warning has usually been disregarded without subsequent ill effects, and the subject has enjoyed the impish satisfaction of proving the doctor wrong and wearing the crown of heroism, it is certain that the danger is by no means hypothetical or negligible

---

* The second Lumleian lecture for 1951 delivered before the Royal College of Physicians on April 12. The first lecture was published on May 26.

For at least one serious communicable disease, poliomyelitis, the predisposing influence of physical exercise has been demonstrated beyond doubt Experimental evidence that fatigue of exhausting exercise lowers resistance of the rhesus monkey to poliomyelitis virus has received clinical support (Levinson 1945) In the San Francisco epidemic of 1930, exhausting exercise preceded the onset of illness in 7 out of 60 patients In one case, after a febrile illness of two days, the patient was sufficiently improved to play in a football match Within a few hours the symptoms of poliomyelitis appeared with extensive paralysis terminating in death

A champion girl swimmer suffering for several days from what was thought to be a digestive disturbance competed, against medical advice, and died of poliomyelitis within thirty six hours

Of 107 boarders in a hostel who competed at an athletic meeting, 21 fell victims to infantile paralysis It appears that when paralytic symptoms establish themselves after physical strain, more particularly if combined with chilling, the polyneuritis is specially related to the muscles employed

The relation of exercise to tuberculosis is not so easy to establish Deaths of famous athletes from pulmonary lesions appear to supply persuasive evidence, but I have an impression that the tuberculous diathesis may be accompanied by a flair for athletics, and, if this is granted, cause and effect are not easily distinguished It must be remembered that athleticism is a peculiar quality, and that the magnificent physique as measured by anatomical standards and by performance is not necessarily the magnificent physique as measured by resistance to disease Apart from exercise as such, exposure to wet and cold, the not infrequent accompaniment of feats of endurance, may lower resistance to this infection

HEAT STROKE AND CRAMP

One danger of violent exercise which is not generally appreciated is that of heat stroke In violent exercise heat is generated, and up to a point with advantage Rise in temperature favours dissociation of hæmoglobin in the tissues and alters the velocity of chemical reactions and the rapidity of diffusion to an extent which increases significantly the rate of lactic acid re synthesis Concentration of blood spares the heart and increases the supply of oxygen to the tissues In the athlete these processes are developed during training, whilst the thermotaxic mechanism maintains a maximum efficiency What is the limit of physiological efficiency? I have myself developed a rectal temperature of 105 8° after running for an hour when the external temperature was 85° To continue for a longer period, as in the case of a marathon race with climatic conditions unfavourable to heat loss—a humid atmosphere and a following wind—might invite a serious danger

Neuroglobin separates out at 108°F, so the critical body temperature is probably a little below this One death occurred on the road during the marathon race at Stockholm in 1912 That more fatalities have not been recorded is a tribute to the capacity of the human body to adjust itself to emergencies, but the marathon race has so far been held only in countries where great heat is not to be expected Nevertheless I have always attempted to represent the danger, and to advise, as a reasonable precaution, that the hottest hours of the day should be avoided

When exhausting exercise is undertaken in circumstances conducive to heat stroke it is impossible to separate the symptoms caused by an accompanying hypoglycæmia I witnessed some alarming psychosomatic and profound metabolic disturbances in the cross country race at the Olympic Cross Country race in Paris in 1924, which took place during particularly humid heat It was interesting to see that the winner, Nurmi, finished completely free from distress, a striking tribute to the capacity possessed by the super athlete for adjustment of any kind

Curiously enough, muscular cramp, the result of salt depletion from profuse sweating, does not occur in marathon runners at least I have not encountered an example Yet I recall the employment some thirty years ago, by a really long distance runner, of a special lemonade which contained sugar and salt The sugar I accepted as a reasonable fuel, the salt I dismissed as a fad, but in the light of subsequent knowledge it would appear that he had empirically hit upon an essential requirement

The occurrence of cramp in lawn tennis players is presumably related to this biochemical factor, but there are clearly other less comprehended elements in cramp, as in swimmers Hyperventilation and excessive loss of carbon dioxide may play a part But, as is well known, cramps occur in circumstances when muscular exercise is in no way concerned

EXERCISE AND THE ABDOMEN

Since duodenal ulceration is by no means uncommon in athletes, surgeons have been at some pains to identify a causative factor in strenuous exercise They have naturally been drawn towards the mechanical side Over thirty years ago, David Wilkie explained the preponderance in males as dependent on a relatively high pylorus and lax duodenum subjecting the hepatoduodenal ligament to strain Fixity of the male duodenum he regarded as predisposing to kinking at the first duodenal angle, and, since regurgitation is impeded, to an unduly long exposure of its first part to acid chyme undiluted by bile or pancreatic juice

Arbuthnot Lane laid even greater emphasis on the mechanical hypothesis In athletic exercises the abdominal muscles are particularly concerned, and their powerful contractions, he pointed out, thrust the viscera into the pelvis The sagging of a full and heavy ileum results in a pull upon the duodenojejunal flexure, the next fixed point As a consequence the duodenum becomes distended, yields in its first (relatively mobile) part, and gives way on its convex surface

At the end of World War I I sat with Lane on medical boards, and on one occasion three young officers with duodenal ulcer were included Two had been runners and one an oarsman of some distinction, and these he regarded as support of his thesis So called psychosomatic medicine had not at that time attained its present day prominence, but even then I hazarded the possibility of a neurogenic responsibility, having regard to the highly emotional temperament that so often characterises the athlete—a point of view that the great surgeon received without enthusiasm

It is possible that the swing to the psychical side in the ætiology of peptic ulceration has been excessive, and that there may be room for a more respectful acceptance of the mechanical or anatomical factor

EXERCISE AND THE NERVOUS SYSTEM

Apart from this gastro intestinal relationship, a few further words will suffice regarding the Nervous System and violent exercise The central nervous system may be affected in any exhausting exercise, presumably from anoxia, but permanent injury does not occur

A paper published in 1876 contained the alarming pronouncement "If any psychologist will take the trouble to trace out the history of each of our prominent pedestrians, he will discover that a very large proportion of them have been subject to some form of madness" What mental or nervous disturbances the writer comprehended under "madness" is open to speculation He may have included fanaticism, infatuation, *monomania*, and the like, to which athletes are, in the eyes of the non athletic, only too prone. So far as the inmates of mental homes afford a guide, there is certainly no indication of a disproportionate athletic contribution.

Exercise as such has no particular bearing; but the circumstances of intense competition may have a considerable emotional reaction. The continuous overflow of impulses to the muscles, the complex processes involved in coördinating skilled movements and focusing attention, the excitement, apprehension, and anxiety experienced especially by the leading exponents so prominent in the limelight—all of these suggest that the "strain" of exercise may have a reasonable meaning if applied to the nervous system. Fatigue and excitement attending athletic competition represent special stimuli for neurotic subjects to lose control, and spectacular demonstrations of a hysterical character are not unknown at the end of a race.

EXERCISE AND THE KIDNEY

Albuminuria, now universally accepted as a negligible sequel of exercise in children and adolescents, was at one time regarded as proof of kidney disease demanding complete cessation of activity and very considerable dietetic restrictions.

Although Pavy had identified a condition he termed intermittent albuminuria, priority should be accorded to Clement Dukes and William Collier for their recognition of its innocence, and tribute paid to their courage for asserting, in the face of eminent opposition, that it necessitated no restrictions or prohibitions of any kind. Their bold uncompromising pronouncements rescued members of our profession from pitfalls, many boys and young men from unnecessary suffering, and parents from exaggerated anxiety and needless expense. Dukes (1905) recognised the complete disappearance of albuminuria in men in whom he had discovered the condition when at school ten or fifteen years previously. Collier (1906, 1907) extended his investigations, in particular to Oxford oarsmen; for albuminuria of exercise is intimately related to the pubertal or postural variety. During the years of growth, the circulation, unstable from defective innervation of the blood vessels, allows serum albumin to transude through the over distended capillaries of the kidney. In the recumbent position albumin disappears from the urine. Its return on assuming the erect attitude is due to compression of the left renal vein against the aorta; indeed cystoscopy may show that the left kidney alone is responsible. In exercise, blood is diverted to situations where it is urgently required, and the kidney, which is very sensitive to oxygen want, is called upon to endure this deprivation. In the vast majority of cases orthostatic albuminuria disappears in early adult life; and, as one would expect, the post exercise albuminuria which is universal in young subjects is inconspicuous in older athletes even after severe exercise, because the vasomotor system is more stabilised. Since calcium metabolism appears to be concerned in the process, we see again the circumstances of growth, the demand of the bony tissues.

I may cite two from a very large number of personal observations (Abrahams 1926).

The urine of a man of 30, after the extreme effort of walking $8^{1}/_{4}$ miles in an hour, contained only 0·1% of albumin, a few hyaline and granular casts, but no blood. Crystals of oxalates were identified. Twelve hours later, no albumin was present.

The urine of another, after running half a mile in World's record time, showed an almost imperceptible trace of albumin precipitated in the cold by dilute acetic acid. Oxalates again were present. This would seem to support the neurogenic explanation of oxaluria.

In my own case, the average of a dozen examinations of urine after an hour's run has been the transient presence of protein 10 mg. per 100 ml. and 30 red blood corpuscles and 4 leucocytes per c.mm.

March Hæmoglobinuria.—This rare condition, in which exercise appears to be the essential causative factor, is in line with orthostatic albuminuria with a special constitutional element. Gilligan and Altschule (1950) who have paid considerable attention to this condition, in recording its occurrence in a young woman, state that of the 76 previous examples one only, described by Vogt (1943), was encountered in a female. It seems probable that so great a sex disparity is inadmissible; instances in females are more easily overlooked or, for obvious reasons, misinterpreted. Exercise qua exercise is not solely responsible, for it has not occurred after the most vigorous cycling. The erect attitude is a sine qua non (Watson and Fischer 1935). Syphilis and other causes of hæmolysis, especially chilling, must be excluded, as well as possible confusion with such a state of red urine as may follow ingestion of large quantities of beetroot.

Blood examination reveals no clue to the peculiarity. The fragility of the red cells is normal, although there is, of course, hæmoglobinæmia. The blood loss is trivial; it has been estimated as less than 16 ml.

The explanation would appear to be an abnormal vaso motor reflex occurring in exercise—a reflex which gives rise to increased blood supply to the liver and spleen and escape of abnormal amounts of hæmoglobin into the blood stream. Lordosis of the spine is apparently an influence, and it is said that the condition can generally but not always be prevented by imposing kyphosis through the application of a plaster jacket.

I have had no personal experience of any case in an athlete.

The temporary *glycosuria*, not infrequent after exercise, is explained by the overflow of adrenaline. It is, of course, negligible.

STITCH

This term accurately applied is any sharp local twinge of pain; Shakspere uses it in this sense, and that great stylist Clifford Allbutt (1898) refers to the agonising stitch of pleurisy. But in common usage the term is restricted to a pain occurring during exercise, usually in the infracostal region. It may be severe enough to cause complete disablement in a track athlete; so we are often importuned for views as to its ætiology and advice for its prevention.

For long it was generally held that stretching of the capsule of the spleen was the cause—naturally an unsatisfactory explanation for its occurrence on the right side of the body. Moreover Barcroft showed that the spleen contracted during exercise.

Capps (1941), in view of its relation to exertion, a full stomach, and exposure to cold as precipitating factors, and relief by rest, explained it on the grounds of ischæmia of the diaphragm, comparable to angina pectoris and intermittent claudication. Some experiments by Conybeare (1932) on students at Guy's Hospital, in whom stitch was induced by taking exercise shortly after a meal, appeared to exonerate the diaphragm, since fluoroscopic observation showed that the movements were full and unimpaired despite the pain.

The most reasonable explanation is that it is of ligamentous origin. Stitch occurs in those situations where the abdominal wall is least able to provide adequate support. When violent jolting movements coincide repeatedly with relaxation of muscles maintaining an intra abdominal pressure and assisting in supporting the viscera, an intermittent tugging occurs on the ligaments supporting the stomach, liver, spleen, and bowel; in fact an acute physiological visceroptosis due to the erect attitude.

Unhappily the ventilation of these scientific considerations does not appear to be of much practical value. The advice to use a tight abdominal binder will naturally receive little gratitude. That the stomach should be as empty as possible is a wise precaution which is not by any means always effective. In fact, it seems as if stitch results from a special anatomical predisposition that cannot be overcome.

The muscle pain that often follows exercise is a minor trauma or an aseptic tissue inflammation. It can be treated accordingly.

URTICARIA

Urticaria may follow exercise quite independently of raised body temperature. But when one recalls how urticaria can be induced by any sort of antigen, by emotional disturbances and mental states of every kind, by heat or by cold, it is not remarkable that exercise may be one if not the only factor responsible for an attack. And since permeability increases with vascular dilatation, a point will be reached when exudation occurs, so that it does not seem necessary to postulate the local liberation of histamine.

"ATHLETE'S HEART"

This term, if legitimately employed, would apply to a heart of superior contractility particularly efficient for the circulatory demands of athletic feats and of violent exercise generally. Instead, its habitual meaning can only be condemned as an unwarranted assumption of some permanent debilitating or deteriorating alteration resulting from an imposition of exceptional severity or from repeated more or less prolonged submaximal efforts. And embodied in such an idea is the presumption of what is known as "heart strain."

It is well known that when once a term gets into literature its eradication is almost impossible, in spite of failure to produce any positive evidence of its existence and even where there is conclusive proof that it does not occur and never did exist. Moreover the term "strained heart" is, especially in connection with athletics, socially acceptable. It carries with it no stigma; on the contrary some prestige accrues through an implication of heroism or martyrdom.

Two sources of fallacy appear to be responsible. First, a prejudiced expectation arising out of the very considerable circulatory demand and the failure to distinguish strain from stress. Secondly, a mistaken interpretation of the symptoms of participants during and after the feat of exertion.

Strain means a hurt or injury from excessive tension when the structure in question is stretched beyond its proper limits. The physiological dilatation of a healthy heart is of a temporary character, and no post-mortem evidence is available of any pathological change. The cases of so-called acute dilatation are almost always unrecognised paroxysmal tachycardia. The permanently enlarged and defective hearts encountered in hypertension and emphysema are in a different category. Either a toxic factor or a degenerative change in the heart muscle itself is present.

Stress may be rightly said to inflict further injury on a heart already damaged, and genuine strain of the muscular tissue may result with rupture of the muscle or a valve. But in all these cases evidence of disease is forthcoming, and it is not with such that investigation of the so-called athletic heart is concerned.

What is the clinical picture of distress in violent exertion? The subject gasps for breath. The face is pale with a pinched expression of suffering. The pulse is weak and rapid. Cold perspiration may be present. Nausea, vomiting, and even unconsciousness may occur. These are, to be sure, alarming to a solicitous onlooker, but they are not the features of cardiac failure, which are cyanosis, over-distended veins, an enlarged liver.

The exhaustion that ensues during or after an extreme effort may possibly be due to adrenal depletion or to an acute hypoglycæmia resulting not from exhaustion of carbohydrate depots but from disturbances in the regulating faculties of the vegetative systems. But the essential feature is vasomotor collapse from inability to integrate tasks beyond the body's scope. The body can deal with a variety of functional stresses if confronted with one at a time, but its resources of adaptation may be overtaxed if several are imposed simultaneously—e.g., malnutrition, circulatory stress, hypoglycæmia, infection, overheating, co-existing mental or physical fatigue, and menstruation, to mention a few of the most familiar. In other words, any instance of severe exhaustion in an athlete cannot be ascribed to physical stress alone but to the coexistence of any influence leading to generalised vascular dilatation, to which some subjects are constitutionally prone. Headache, precordial pain, nausea, vomiting, disorientation, collapse, and unconsciousness may be produced, yet these symptoms, however alarming, have no baleful significance. One recalls the historic marathon race in London in 1908 when the Italian, Dorando, staggered blindly into the Stadium, and, according to picturesque journalistic exaggeration, lay for a time between life and death. On the following day he had completely recovered and he subsequently ran a considerable number of marathon races.

It is not denied that such a state ought if possible to be avoided, but an appreciation of the true state of affairs transfers the lesion from the heart about which solicitude is usually mistakenly expressed. Even in a perfectly healthy subject undertaking strenuous exertion, sickness and other symptoms may result from cerebral anæmia, since on cessation of the exercise the pumping action of the leg muscles ceases, stagnation occurs, and the volume of blood returning to the right auricle is insufficient to maintain an adequate arterial blood-supply to the brain. Some very efficient athletes are prone to fainting and collapse through a general vagotonic reaction. I have often encountered this during so trivial an ordeal as taking the blood-pressure; another familiar example is the prick of a needle in a hypodermic injection or blood examination.

Adoption of the recumbent position, deep breathing, pressure on the abdomen, and flexion of the legs and arms will substantially reduce the symptoms and accelerate recovery.

At one time oxygen inhalations were a favourite therapeutic measure, and cylinders were kept in readiness on athletic grounds. But apart from a psychological effect, oxygen can have no restorative value, since the oxygen requirement falls below the oxygen income available from ordinary air. And a recovery from fatigue is limited by the rate of return of lactic acid into the muscles from the blood and inactive tissues which is not affected by oxygen.

The possibility of hypoglycæmia is an attractive explanation of the symptoms after long-continued exhausting exercise. This applies particularly not to comparatively short intense efforts, where the circulatory system bears the brunt, but to those of long duration. Gordon, Levine, and their fellow-workers (1925) found a close correlation between the physical condition of runners at the finish of a marathon race and the level of the blood-sugar. They advised an adequate carbohydrate ingestion before and during any such protracted and vigorous muscular effort (Levine and Gordon 1924). My observations upon leading British marathon runners have not shown any evidence of hypoglycæmia, nor have they found it desirable or practicable to take any form of nourishment during the race. Considered as a purely academic problem, what is the likelihood of hypoglycæmia developing? It is estimated that in a man weighing 60 kg—a reasonable average in a marathon runner—the liver weighs 1500 g. and contains 15% glycogen. The muscles constituting 40% of the body contribute 1·5% glycogen or, in all, 585 g. In a run of 2½ hours' duration at a speed demanding the inspiration of 3 litres of oxygen per minute, 560 g. of carbohydrate would be consumed, and since in addition some fat is burnt, a margin should be available. It is doubtful therefore whether preparatory ingestion of sugar is necessary or advantageous, though it is at least harmless; but to suck glucose sweets during the race, as the American workers recommended, is not favoured by a practical athlete.

As a final word upon heart strain, an appeal to statistics may be pertinent. Notwithstanding the lack of positive evidence of any pathological change, an alternative hypothesis has been a sort of slowly progressive deterioration. Thus a writer on the subject of arteriosclerosis (Plesch 1932) asserted that athletes showed marked arterial degeneration by the age of 35 or 40 and that most of them die before 50. In the subsequent correspondence challenging the accuracy of this opinion, it appeared that his interpretation of athletes was big persons of excessive weight, stage acrobats, and others whose occupations had hazardous associations. In these, the physical element was trifling compared with nerve strain, the anxieties attending intermittent unemployment and hardships, together with the possible influence of syphilis and over indulgence in alcohol. To indict athleticism in such circumstances would be as illogical as to draw conclusions about the malevolent effects of high altitudes from the mortality rate in parachute testers.

In 1873, Morgan, the Manchester consulting physician, himself an oarsman of distinction, undertook the laborious investigation of the life histories of all who had rowed in the Universities' Boat Race between 1829 and 1869. In 1904, Meylan repeated the investigation in the case of Harvard oarsmen between 1832 and 1892. The results yielded a close correspondence, showing a life expectation nearly five years' longer than that of the selected risks in insurance tables. More recently Cooper and his colleagues (1937) found that of 100 oarsmen at Ormond College, Melbourne University, 17 had died from natural causes during the fifty years succeeding their athletic career. The expected mortality of men of the average age of 21 over the same period was, as quoted by the Australian Mutual Provident Society, 31.8%.

It may be objected that such subjects were exceptional material, and that notwithstanding their longevity it could not be denied that even this might have been longer had they abstained from strenuous exertion in their early life—an unanswerable argument.

No such organised inquiry has been extended to track athletes. My own observations enable me to submit many examples of octogenarians and a few nonagenarians who in their youth were outstanding runners and have enjoyed perfect health and present in their advanced age a condition that most men twenty years their junior could not surpass. No controls are available to permit comparisons between athletes who have continued to follow the hygienic life of active participants in sports and outdoor recreations, moderation in living, and scientific feeding, and those who live fast, overeat, drink heavily, and drive themselves to exhaustion especially with mental strain.

How is it possible to assess the causes of degenerative changes in a man who in his youth was a trained athlete and in later years carried heavy business or professional responsibilities? Regard, too, must be paid to the difference in temperament between the scholar of sedentary habit and the athlete whose ardent spirit and activity drive him into enterprises and risks, not free from dangers, which the scholar in his sheltered life is more likely to escape.

EXERCISE IN HEART DISEASE

Since some criticism is advanced of the prudence of undertaking strenuous exercise even in the case of the completely healthy, it might seem that no momentary difference of opinion is possible in subjects of admitted organic cardiac disease. And yet as clinicians we must not submit to summary decision. It is perhaps a natural conclusion that valvular disease of the heart is a crippling disorder that hampers efficiency and demands extreme care in the way of prohibiting exertion lest deterioration ensues. There is, however, ample evidence that valvular disease as such need impose no handicap so far as capacity for exertion is concerned.

I have seen a magnificent sprinter with a much enlarged left ventricle, the consequence of aortic regurgitation. The best middle distance runner of his generation had mitral disease. Jokl (1940b) has recorded the case of a man of 32, winner of 14 marathon races, whose heart lesion—aortic and mitral disease resulting from rheumatic fever at the age of 9—was discovered on routine examination. It is clear that circulatory disease even if so severe that it acutely threatens life may not at all impair physical efficiency; that disease of the aortic valve itself gives rise to no symptoms; that mitral stenosis will permit of full physical capability so long as the myocardium is healthy.

Admittedly the position of a practitioner is not a comfortable one when approached for advice on the extent of exertion permissible in a boy or girl with unmistakable valvular disease. To play for safety by complete prohibition may well be a policy in his own interest but one irreconcilable with his conscience. The responsibility of forbidding exercise may be as great as that which he is compelled to accept by inviting a certain risk. For the ill effects must be contemplated. No boy can gain the companionship to which he is entitled and which forms an essential element in his school life without the special associations of games and other forms of competitive exercise. To grow up with a belief in his physical inferiority is a serious blow to his character with an adverse influence upon his attitude to life. The danger of moral deterioration may be worse than physical injury unless those in authority can find efficient substitutes for exercise, and their task is far from easy. The practitioner will be influenced by the circumstances of each individual case and partly no doubt by his own prejudices.

Apart from athleticism what should be the attitude in general towards prohibition or limitation of exercise and the imposition of inactivity in subjects of cardiac disease? Just as rest of injured parts is the oldest and most valuable of all methods of treatment, this, like all other therapeutic measures, may be injudiciously or excessively applied. Emphasis upon rest and complete abstinence from activity is proper in the acute stage of cardiac disease and in convalescence; but is the traditional insistence upon continued or prolonged rest justifiable?

Infection has more to do with cardiac failure than strain upon or mechanical defect in the heart itself. In children with valvular disease, both congenital and acquired, there is generally an unwarranted fear of exercise; their exercise tolerance may be satisfactory as compared with normal children. If failure ensues it is due to relapsing rheumatism.

In the case of congestive failure the patient should be allowed out of bed as soon as severe dyspnœa at rest has subsided, although activity should, of course, be kept below the symptomatic threshold of pain and dyspnœa. As cardiac output is less in the sitting or erect posture than when recumbent, a little activity may actually be resting the heart. Restriction of activity reduces blood flow to a minimum and may favour the development of thrombi in the venous system or the arteries, and œdema of lungs. Infarction of the lungs and myocardium is often observed in patients subjected to unduly prolonged rest. Moreover cardiac neurosis is induced by insistence on excessive caution.

empty as possible is a wise precaution which is not by any means always effective. In fact, it seems as if stitch results from a special anatomical predisposition that cannot be overcome.

The muscle pain that often follows exercise is a minor trauma or an aseptic tissue inflammation. It can be treated accordingly.

URTICARIA

Urticaria may follow exercise quite independently of raised body temperature. But when one recalls how urticaria can be induced by any sort of antigen, by emotional disturbances and mental states of every kind, by heat or by cold, it is not remarkable that exercise may be one if not the only factor responsible for an attack. And since permeability increases with vascular dilatation, a point will be reached when exudation occurs; so that it does not seem necessary to postulate the local liberation of histamine.

"ATHLETE'S HEART"

This term, if legitimately employed, would apply to a heart of superior contractility particularly efficient for the circulatory demands of athletic feats and of violent exercise generally. Instead, its habitual meaning can only be condemned as an unwarranted assumption of some permanent debilitating or deteriorating alteration resulting from an imposition of exceptional severity or from repeated more or less prolonged submaximal efforts. And embodied in such an idea is the presumption of what is known as "heart strain."

It is well known that when once a term gets into literature its eradication is almost impossible, in spite of failure to produce any positive evidence of its existence and even where there is conclusive proof that it does not occur and never did exist. Moreover the term "strained heart" is, especially in connection with athletics, socially acceptable. Some very efficient athletes are prone to fainting and collapse through a general vagotonic reaction. I have often encountered this during so trivial an ordeal as taking the blood-pressure; another familiar example is the prick of a needle in a hypodermic injection or blood examination.

Adoption of the recumbent position, deep breathing, pressure on the abdomen, and flexion of the legs and arms will substantially reduce the symptoms and accelerate recovery.

At one time oxygen inhalations were a favourite therapeutic measure, and cylinders were kept in readiness on athletic grounds. But apart from a psychological effect, oxygen can have no restorative value, since the oxygen requirement falls below the oxygen income available from ordinary air. And a recovery from fatigue is limited by the rate of return of lactic acid into the muscles from the blood and inactive tissues which is not affected by oxygen.

The possibility of hypoglycæmia is an attractive explanation of the symptoms after long-continued exhausting exercise. This applies particularly not to comparatively short intense efforts, where the circulatory system bears the brunt, but to those of long duration. Gordon, Levine, and their fellow workers (1925) found a close correlation between the physical condition of runners at the finish of a marathon race and the level of the blood-sugar. They advised an adequate carbohydrate ingestion before and during any such protracted and vigorous muscular effort (Levine and Gordon 1924). My observations upon leading British marathon runners have not shown any evidence of hypoglycæmia, nor have they found it desirable or practicable to take any form of nourishment during the race. Considered as a purely academic problem, what is the likelihood of hypoglycæmia developing? It is estimated that in a man weighing 60 kg.—a reasonable average in a marathon runner—the liver weighs 1500 g. and contains 15% glycogen. The muscles constituting 40% of the body contribute 1.5% glycogen or, in all, 585 g. In a run of 2½ hours' duration at a speed demanding the inspiration of 3 litres

Respiratory System and Smoking—The condition of the patient's lungs and heart and his blood-pressure are assessed, and perhaps breathing exercises are instituted Patients with bronchitis and asthma are operated on between April and October under local analgesia, 3 were so treated As postoperative "chestiness" and cough are more common in habitual smokers, with consequent strain on the repair, such patients are advised to smoke but one cigarette or pipe after each meal

Septic Foci—Dental and nasal sepsis are eliminated

Varicosities—3 men were operated on for varicose veins and ulcers at the same time as the herniotomy In 1 of them a sinus persisted in the hernia scar until he died three and a half years later, indicating the advisability of eliminating sepsis first and doing one operation at a time

Double Herniæ—The hernia was double in 36 men (18%) Since May, 1943, each hernia has been operated on separately, at an interval of ten days or more, the larger hernia being done first The late Percival Cole suggested to me that the "yield" in the second hernia acts as a safety valve to the increased abdominal contents and wall rigidity following the reduction and herniorraphy When both herniæ are closed simultaneously, the intra abdominal contents may be increased and the abdominal wall rendered more rigid Further, with a double herniotomy there is the risk of the second one becoming infected during the prolonged procedure

ANALGESIA AND ANÆSTHESIA

As relaxation and absence of heaving and oozing are essential, and vomiting, coughing, and retention of urine afterwards are detrimental to cure, the choice of anæsthetic is all important

Local analgesia (amethocaine 1 in 2000 with adrenaline 2 minims of 1 in 1000 per fluid oz) is used in patients aged more than sixty five, it is inserted through only two punctures, and a relaxed and bloodless field is assured For the patient's comfort light anæsthesia is induced with thiopentone or with open ether, it is discontinued when the hernial sac has been removed This combination is safe and consistently gives ideal conditions, with minimal postoperative disturbance

Spinal Anæsthesia—A low spinal anæsthetic (Dodd 1945) is good in patients aged up to sixty five, but I lost a patient aged seventy two immediately after the "spinal" was given The blood pressure should be recorded throughout the operation, for a gross fall may take place and need correction My assistants say that they cannot estimate the blood-pressure with the finger tips, it must be measured 'Methedrine' (Dodd and Prescott 1943) is given to restore a low blood pressure

General anæsthesia alone is perfect in some patients, but in others it does not give the relaxed, quiet, and bloodless field which is essential Tension and straining split the aponeurosis, even in young patients

OPERATION

Suture Material—Since 1929, interrupted linen thread sutures have been used—no 50 for the sac neck and the detensioning suture between the rectus sheath and the pubic spine, and no 90 for the remainder It is so satisfactory that I am reluctant to change for floss silk (Maingot 1945), 'Nylon' (Moloney et al 1948), or stainless steel wire (Abel and Hunt 1948)

External Oblique Aponeurosis—After the skin and fat have been incised, the external oblique aponeurosis is cleaned down to the thigh, and upwards and inwards to the outer border of the rectus sheath and to the insertion of the upper and lower pillars of the external abdominal ring into the face of the pubic bone (the normal external ring is internal to and above the pubic spine) The upper parts of the adductor longus and pectineus muscles are uncovered to reveal the outlet of the femoral canal, and possibly an unnoticed femoral hernia The external oblique aponeurosis is split from the apex of the external ring almost to the superior iliac spine The two leaves are dissected freely up and down

Dislocation of Spermatic Cord—The spermatic cord or round ligament, with the surrounding fat, is wiped upwards from the shiny deep aspect of Poupart's ligament, from a point internal to the pubic spine It is lifted on the finger from the posterior wall of the inguinal canal, for it may conceal a direct sac

Division of Cremaster Muscle—The cremaster is divided from the conjoined tendon and the internal oblique muscle at the internal abdominal ring The branch to the spermatic cord from the deep epigastric artery at the internal ring is exposed and divided, a step which completely uncovers the inner edge of the internal inguinal ring in the transversalis fascia (fig 1)

Division of Spermatic Vessels—In 13 patients aged more than sixty five the bulk of the spermatic cord was further lessened by dividing the spermatic vessels but not the vas deferens and its artery 3 testes atrophied after this, but only 2% in the patients of Grace and Johnson (1937)

Orchidectomy—In men over seventy, with poor tissues and a large hernia, the testis was removed and the inguinal canal abolished When the need is plain, this is a useful step A man aged fifty five, weighing 22 stone, whose repair included this, has been cured for five years

Lipoma of Spermatic Cord—A considerable amount of extraperitoneal fat was excised in 22 herniæ to make the spermatic cord less Fat, by burrowing through the internal abdominal ring or splits in the transversalis fascia, predisposes to another hernia

Hernial Sac—The sac, direct or indirect, or both, is transfixed and divided at the parietal peritoneum, and the fatty "shoulder" often found on the inner side of an oblique sac is removed The bladder is separated from a direct sac Three inguinal sacs, an internal direct, an external direct, and an indirect, have recently been excised from the same patient

Digital Exploration of Peritoneal Cavity—A finger is inserted through the opened sac into the peritoneal cavity, exploring for other sacs, femoral or direct (fig 2) Maingot (1945) also advises this step 3 people had three sacs (two inguinal and one femoral), and 36 had two Failure to remove a second sac leads to a "recurrence"

Transversalis Fascia—The restoration of transversalis fascia is considered vital to the cure It is separately closed or reefed with interrupted stitches fitting it snugly round the spermatic cord to reconstitute the internal abdominal ring

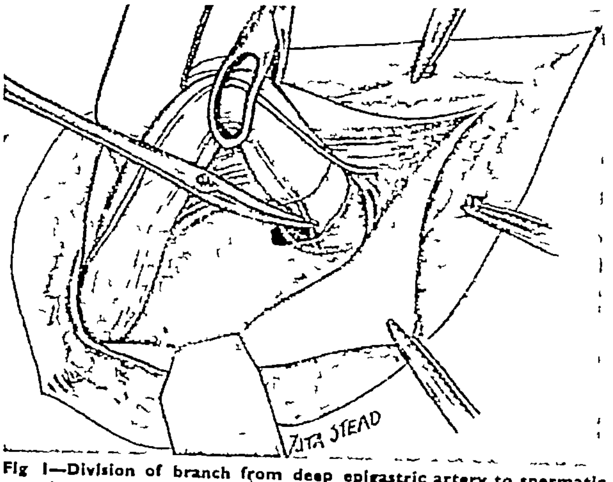

Fig 1—Division of branch from deep epigastric artery to spermatic cord completely exposes opening of internal abdominal ring in transversalis fascia.

John Hunter had what appears to have been myocardial infarction at the age of 45 Twelve years later he suffered from severe anginal attacks He died suddenly at the age of 65 At necropsy, extensive disease of the coronaries with calcification of the aortic valves and the scars of infarcts were found He lived, therefore, for twenty years after the onset of symptoms indicating serious heart disease Is one to assume that he would have lived longer if he had resigned himself to an invalid or semi invalid existence, and would his happiness have been increased or reduced by such a régime ?

James Mackenzie first experienced angina of effort in 1907 and symptoms of a myocardial infarct in 1908 At his death in 1925, extensive atheroma of the coronaries with several healed infarcts were found Thus he had led an active and useful life for seventeen years after his first infarct Was the great cardiologist a poor therapeutist in regard to his own case ?

RADICAL CURE OF INGUINAL HERNIA IN THE ELDERLY

HAROLD DODD
Ch M Lpool, F R C S

SURGEON TO KING GEORGE HOSPITAL, ILFORD, THE ROYAL HOSPITAL, RICHMOND, AND THE ROYAL LONDON HOMŒOPATHIC HOSPITAL

IN young people herniæ often provoke feelings of inferiority and are sometimes used as a reason for avoiding heavy work In the elderly they are a common cause of capricious behaviour and reluctance to perform simple tasks, such as shopping, and they are responsible for much anxiety as well as inconvenience

The Registrar General reports 3305 deaths from hernia in England and Wales in 1948 Many of these must have followed an emergency operation, and might have been avoided by a well planned routine operation Such an operation can be performed successfully even in the elderly

Landers (1938) found that 1 in 4 industrial employees aged more than fifty were ruptured, a third of the herniæ being double, he believed that ruptures follow the middle age weakening of the supporting tissues He noted that 25% of hernial repairs fail

Gibson and Felter (1930) published very good results in 155 patients aged over fifty, the recurrence rate being 3 8%

Grace and Johnson (1937), writing on herniotomy in 1032 patients aged over fifty, found that the hernia was primary in 90% and recurrent in 10% Their mortality rate was 3% Their repair was of the Bassini type They tried to make a strong posterior wall of the inguinal canal by suturing the conjoined tendon with transversalis fascia or in a separate layer to the shelving edge of Poupart's ligament, especially in direct hernia The spermatic cord was usually transplanted, and in about half the cases the external oblique aponeurosis was sutured behind it When the hernia was recurrent, large, sliding, scrotal, irreducible, or uncontrollable by a truss, the spermatic vessels (not the vas) were divided, the recurrence rate was distinctly smaller after this than without it

25% of the primary herniæ and 34% of the recurrent herniæ recurred Grace and Johnson remark that those rates of 25% and 34% may discount the effectiveness of the procedure, but many patients had but a slight return, and the symptomatic results were excellent In 611 patients the recurrence rate was 21%, with indirect sac, with direct sacs 32%, and with direct and indirect sacs 35 8%, the average being 25 8%. After wound infection the recurrence rate was 40%

Grace and Johnson agree with Page (1934) and Mayo and Mayo (1937) that a simultaneous double herniotomy carried a higher recurrence rate (31 5%) than did unilateral herniotomy (19 5%) with an oblique sac it was 25 2%, and with a direct sac 37 2%

Sainburg (1950) reported 142 cases in patients between sixty and ninety eight years of age, 25 of these patients were unsuitable for operation, and 69 of the 117 operations were emergency ones He holds that circulatory diseases, bronchitis, obesity, enlarged prostate, renal failure, and cerebral thrombosis contra indicate operation Careful preoperative examination is therefore essential He used much the same method of repair as is described below He suggests that the spermatic cord should be resected because the testis will usually be nourished by its intact scrotal attachments, necrosis of the testis followed in only 2% of such resections Double herniotomies were done in two operations The patients were got up and about as soon as possible The infection rate was 6·5% A follow up of 56 patients seen from six months to five years after operation revealed 6 recurrences (10 7%) but, like those reported by Grace and Johnson (1937), they did not cause any symptoms In the emergency operations 11 of 69 patients died (15 9%), but in the other operations all the patients survived

I suggest that operation for all herniæ as soon as they are seen will save suffering and premature death of patients and inconvenience to patients' families and to our profession The results will be improved and our national efficiency increased individually and collectively

In September, 1938, I began operating on all hernia in patients aged more than one year of age On the rare occasions when operation was refused, a truss was ordered The results obtained since 1934 in 200 patients who were over fifty years old and treated by operation are presented here The age groups were as follow 50–60, 104, 60–70, 68, 70–80, 24, over 80, 4 There were 182 men and 18 women

PREOPERATIVE EXAMINATION

Poor Tissues—In elderly patients herniæ are often associated with some constitutional ailment The patient may be getting feebler and his muscles may be wasting, as in 22 (11%) of patients in my series Other patients are obese and flabby from lack of exercise, overeating, and excessive drinking, the muscles and aponeuroses being permeated with fat Rehabilitation is needed before and after operation, and at operation the use of small needles and fine sutures make good reconstructions possible, where thick sutures—e g, catgut—and large needles would split fragile tissues and render a cure unlikely

Rectum and Prostate—The rectum is examined to exclude carcinoma (found on 3 occasions) and enlarged prostate The urinary function is checked, for prostatectomy may be necessary 2 octogenarians were cured of herniæ after prostatectomy

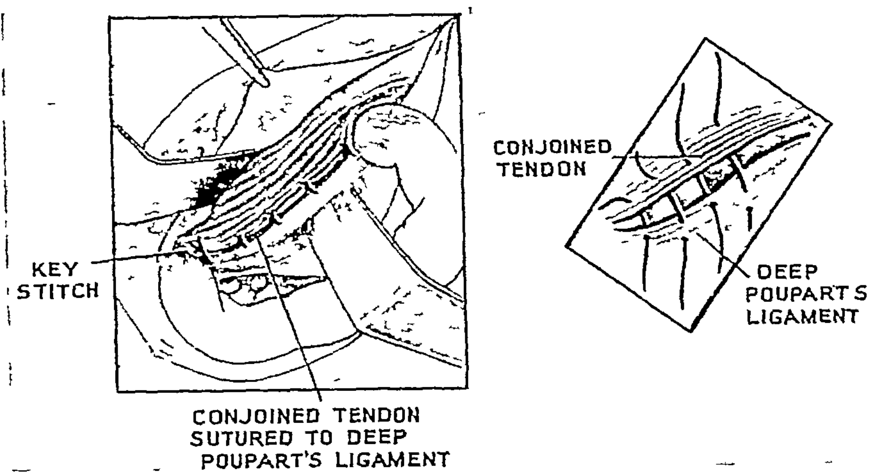

Fig. 4—Stitches approximating conjoined tendon to deep Poupart's ligament (left) take up different bundles of fibres to spread strain (right).

appeared since the inguinal repair. A woman, aged fifty, who had been cured of an indirect left inguinal hernia and a left femoral hernia, was treated ten years later for a right inguinal hernia (direct and indirect) and a right femoral hernia. An inguinal hernia has appeared in 3 men after a femoral herniorraphy.

Hydrocele.—In 5 cases a hydrocele was treated at the same time as the hernia.

Recurrent Herniæ.—17 herniæ (8·5%) were recurrent, 1 was twice recurrent. All the patients continue cured. A recurrence indicates, but never contra-indicates, another operation.

Carcinoma of Rectum and Colostomy.—3 patients had carcinoma of the rectum, 2 of them with colostomies begged for operation because the hernia was troublesome. The repairs remained sound until the patients died after three and a half years and one year. The third patient reported with an enormous left inguinal hernia, and the rectal carcinoma was discovered on examination. The hernia was treated, and the neoplasm was resected six weeks later, but the patient died from this. A fourth man successfully withstood resection of a carcinoma of the rectum five years after the herniorraphy.

RESULTS

Postoperative Deaths.—3 men (1·5%) died soon after the operation: the first half an hour later from asphyxia, while unconscious and unattended for a short time; the second from a streptococcal infection in the second of bilateral herniæ treated at the same time, and a pulmonary embolus; and the third from a perforated diverticulum of the descending colon five days later.

Later Deaths.—There have been 19 deaths since the operation from causes apparently unrelated to the hernia. In all instances the relatives said that the hernia had been satisfactory. The repairs of 16 of these patients, seen from six weeks to four years before their death, were sound.

Untraced Patients.—It was impossible to trace 4 patients.

Examined Patients.—174 patients have been specially examined during 1949 and 1950, from fifteen years to eighteen months after operation.

Recurrences.—5 recurrences (3%) were found. If one man who was re-treated over five years ago is excluded, the rate is 2·4%. Of 78 persons seen whose repair was more than five years old, 4 had a recurrence at four, six, seven, and nine years later, giving a recurrence rate of 5·4%; excluding the re-repair it would be 4%. The details of these 5 recurrences are as follow:

(1) Man, aged 52, R.I.H. (direct), Bassini in 1937, recurred in 1941. In 1944 second operation, Bassini with a Tanner "slide" and exteriorisation of spermatic cord. In January, 1950, sound.

(2) Man, aged 59, L.I.H. (indirect), operation in 1939 (Bassini), reappeared in November, 1948; symptomless, wears a truss.

(3) Man, aged 64, D.I.H. (direct), operation in May, 1941, at one session. The second—i.e., the left—recurred in autumn, 1947; symptomless, truss unnecessary, repair declined.

(4) Man, aged 53, D.I.H. (indirect), operation in May, 1942, one session (Bassini), left second; small symptomless recurrence (left) in May, 1949; truss unnecessary; re-repaired in March, 1950, "internal direct" sac removed.

(5) Man, aged 84, D.I.H. (indirect), scrotocele, operation in April, 1948 (Bassini Tanner Halsted), at separate operations; in September, 1949, small right symptomless bulge.

It is said that a surgeon never sees his recurrences, but these were found by the follow-up examination. The patients had consulted no one.

Simultaneous Double Repair.—The danger of repairing a double hernia at one session is illustrated by the man who died from septicæmia and a pulmonary embolus that originated in the second hernia, and by 2 of the recurrences being in the second of double herniæ treated together. Of the 36 cases of double herniæ 24 were dealt with at separate operations, with 1 recurrence, and 12 were repaired at one operation, with 2 recurrences.

Five-year Results.—The cases followed up five or more years after operation may be analysed as follows:

	No. of cases
Patients operated on five or more years ago	93
Patients died from the operation	3
Patients died since the operation	9
Patients untraced	3
Patients seen over five years after the operation	78
Recurrence (one now cured over five years)	4
Five-year cures	96%

A patient, aged seventy-five at operation, worked as a rent collector until he was eighty. Several men over seventy years of age are still gainfully employed—e.g., a bus driver, aged seventy-three—and many are satisfyingly occupied by house and garden work.

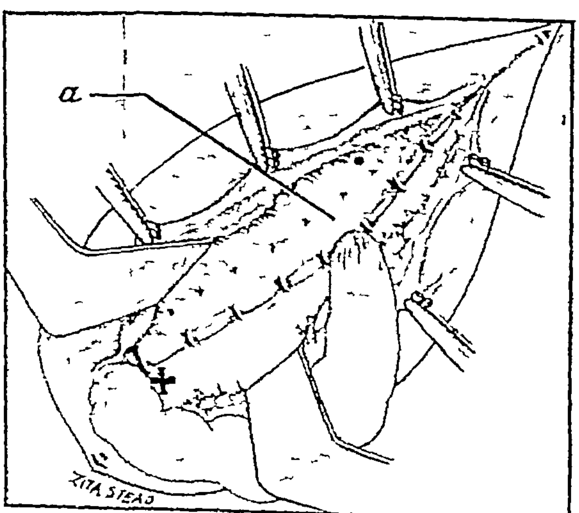

Fig. 5—Closure of external oblique aponeurosis by overlapping and new external ring well removed from pubic spine (+): *a* upper leaf of external oblique aponeurosis sutured to lower leaf by overlapping about ¹/₂–³/₄ in. behind the spermatic cord.

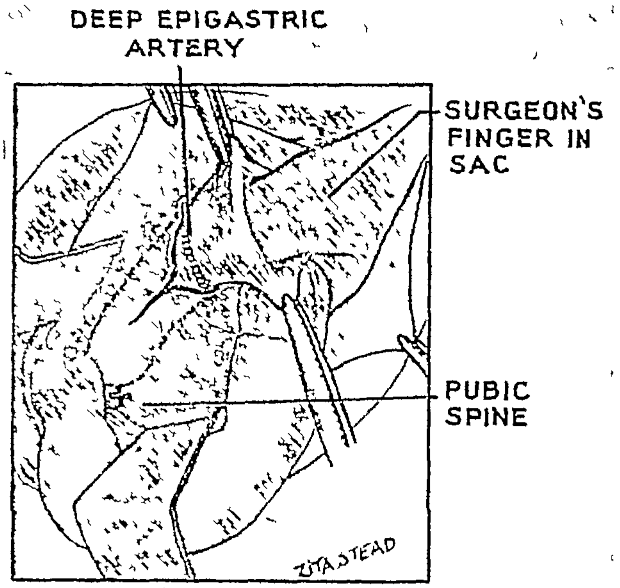

Fig 2—Surgeon s index finger exploring inferolaterally to pubic spine (+) for possible direct or femoral sacs

Tension in Conjoined Tendon Tanner Slide—The conjoined tendon varies in height above Poupart's ligament and in its muscular and aponeurotic substance Ordinarily it can easily be approximated to Poupart's ligament (fig 3B) after having been relaxed with a stout suture between the outer edge of the rectus sheath and the periosteum of the pubic spine

When the conjoined tendon is poor, Tanner's (1942) procedure is invaluable This consists in sharp dissection of the external oblique aponeurosis from the internal oblique to the midline of the abdominal wall A "hockey-stick" incision is made in the internal oblique aponeurosis, curving upwards and outwards from the symphysis pubis for 3 or 4 in to within $^{1}/_{2}$ or $^{3}/_{4}$ in of the outer border of the rectus muscle (fig 3A, B, and C) In this way an attenuated conjoined tendon can be readily sutured to Poupart's ligament from the detensioning stitch between the rectus sheath and the pubic spine The threads are inserted through different portions of conjoined tendon and of Poupart's ligament to avoid splitting their fibres (fig 4, right)

The "slide" incision exposes a crescentic area of pyramidalis and rectus muscles which fuses with the anterior rectus sheath No weakness of the part has been observed in the 102 patients submitted to this "slide" procedure

External Oblique Aponeurosis and Inguinal Canal—The upper leaf of the external oblique aponeurosis overlaps the lower for $^{1}/_{4}$ or $^{3}/_{8}$ in Its preliminary mobilisation permits the external ring to be made at, or even just inside, the pubic spine

Obliteration of Inguinal Canal—When the tissues are poor and the sac is direct, the external oblique aponeurosis is closed behind the spermatic cord, a new external ring is made just outside the internal ring, and the pillars of the original external ring are closed over the pubic spine (fig 5)

Fascial grafts taken from the external oblique aponeurosis closed the gap between the conjoined tendon and Poupart's ligament in 9 men Occasionally the edges of the graft were sutured, forming it into a sheet of aponeurosis With the Tanner slide, grafts are seldom needed, moreover, they tend to split the conjoined tendon and Poupart's ligament

Repair—The techniques used were as follow

(1) The original Bassini repair	104 cases
(2) Bassini method plus the Tanner "slide"	58
(3) Bassini, Tanner "slide," and exteriorisation of the spermatic cord (Halsted)	44
(4) Bassini with fascial graft	4
(5) Halsted operation, including 5 fascial grafts	26 ,,
(6) Division of spermatic vessels	13 ,,
(7) Excision of testicle	24 ,,

POSTOPERATIVE TREATMENT

Getting Up—Most patients got up in fourteen to twenty days Since 1944 they have stood up a day or two after the operation and returned home in twelve days, with no discouragements so far

Abdominal Supports—To avoid stretching of the lower abdominal wall, and therefore of its openings, obese and frail people have been fitted with no 1 Curtis abdominal belts

FINDINGS AT OPERATION

The types of hernia found at operation are shown in the accompanying table

Type of inguinal hernia	No of cases	No of indirect sacs	No of direct sacs	No of herniæ with both direct and indirect sacs
Unilateral	164 (*82%*)	122 (*74%*)	19 (*11 5%*)	23 (*14%*)
Bilateral	36 (*18%*)	46 (*64%*)	13 (*18%*)	13 (*18%*)
Total	200	168 (*71 2%*)	32 (*13 5%*)	36 (*15 3%*)

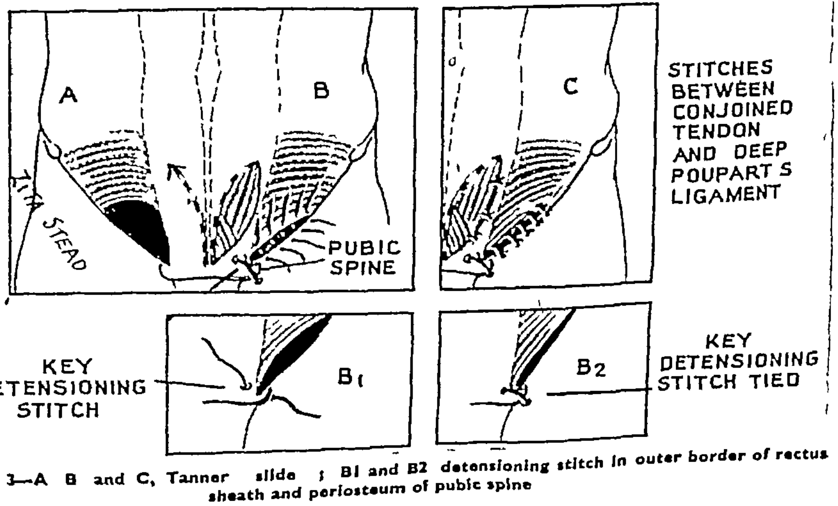
COMPLICATIONS

Retention of Urine—2 men (one over eighty) who had emergency operations for hernia developed persistent postoperative retention of urine, and prostatectomy was successfully performed

Atrophy of Testis—Although the results as regards hernia were good, the testis atrophied in 10 cases 7 after a Bassini repair, and 3 after division of the spermatic vessels For this reason care must be taken that the inguinal rings are not made too tight

Subsequent Other Herniæ—8 patients developed a hernia on the other side and an umbilical hernia Some have been treated

Femoral Herniæ—In 4 cases a femoral hernia was also present and treated, and in 3 cases a femoral hernia has



A
B
C
PUBIC SPINE
WHITSTEAD
STITCHES BETWEEN CONJOINED TENDON AND DEEP POUPART S LIGAMENT
KEY DETENSIONING STITCH

B2
KEY DETENSIONING STITCH TIED

Fig 3—A B and C, Tanner slide ; B1 and B2 detensioning stitch in outer border of rectus sheath and periosteum of pubic spine

spared much tribulation. Constipation in the breast fed infant is in fact only one of many imaginary disorders in pædiatrics (Gordon 1951).

SUMMARY

1. The bowel rhythm was investigated in 1499 infants seen in infant welfare centres.

2. In breast fed infants, in the first month, stools are frequent, often 4 or more a day; in the third, fourth, and fifth months, some 40% of such infants miss a day, and it is not uncommon for the delay to be a week; in the second six months of the first year, breast fed infants go regularly once or twice a day.

3. In bottle fed infants the initial frequency is not so definite. But it is exceptional for a bottle fed infant to miss a day, and should it do so, an organic lesion should be suspected.

4. It is suggested that mistaken efforts to remedy the bowel infrequency of healthy breast fed infants is one of the main causes of habitual constipation in later life. *As breast-feeding is diminishing, both in incidence* and duration, chronic constipation may be expected to become less of a problem. There is indirect evidence that this is already happening.

OPHTHALMOSCOPIC DETECTION OF MICROFILARIÆ OF ONCHOCERCA VOLVULUS

J. W. R. SARKIES
M.R.C.S., D.O.M.S.
COLONEL, INDIAN MEDICAL SERVICE (RETIRED); TEMPORARY OPHTHALMOLOGIST, COLONIAL MEDICAL SERVICE

MANY workers have described the observation of microfilariæ in the aqueous humour of the eye with a slit lamp and corneal microscope. Estrada (1942) published a series of 11 cases of onchocerciasis, in which he described microfilariæ seen in the vitreous humour with an ordinary ophthalmoscope, using lenses from plus 20 to plus 50 dioptres; the simplicity of this method is very attractive, especially under rural conditions. It was decided therefore to compare results obtained by ophthalmoscopy and by slit-lamp examination in native schoolchildren and industrial workers of the lower Volga district of the Gold Coast.

It was found that microfilariæ could be seen in the aqueous humour with an ophthalmoscope incorporating a plus 20D to a plus 28D lens, held 3·5–5·0 cm. from the centre of the anterior chamber—i.e., at the focal distance of the lens used. The whole of the pupillary area is illuminated by reflection from the fundus; and since the embryos are seen in silhouette, the margin of focus is greater than with a corneal microscope using direct illumination from a slit lamp. For this reason the embryos can be recognised more rapidly and, in cases where they are scanty, are less likely to be missed with an ophthalmoscope. In none of the cases in this series were microfilariæ seen in the vitreous humour with lenses of this power; nor were they seen with a plus 4D lens in the ophthalmoscope held at about 25 cm. from the eye, although other small opacities in the vitreous could be seen in this way.

All the persons were examined under a mydriatic, first with an ophthalmoscope and then with a slit lamp; a dark room was not available, but the examinations were made in a shady hut, a standard battery model Lister Morton ophthalmoscope being used. The instrument is brought towards the eye, with the light directed on the optic disc (which in pigmented races gives an appreciably brighter reflex than does the rest of the fundus), until the pupillary margin of the iris comes clearly into focus. At this point microfilariæ can be seen, if present, silhouetted against the illuminated pupil as tiny black threads swimming through the aqueous humour with a rippling motion; this motion is quite characteristic and differentiates microfilariæ from other opacities—e.g., cells in the aqueous humour, threads of persistent pupillary membrane, and small particles floating in the lacrimal secretions on the anterior surface of the cornea. A microfilaria can be brought into clear focus by moving the ophthalmoscope slightly backwards or forwards according to the position of the embryo in the anterior chamber.

MICROFILARIÆ FOUND BY OPHTHALMOSCOPY AND WITH SLIT LAMP

—	School children	Industrial employees	Total
Total examined	111	204	315
Microfilariæ (Mf.) in skin smears	38	150	188
Mf. seen by ophthalmoscopy alone	6	14	20
Mf. seen by ophthalmoscopy and with slit lamp	4	30	34
Mf. seen with slit lamp alone	0	1	1
Percentage of cases with positive skin smears showing Mf. in aqueous humour	26	30	28·6

RESULTS

The results are given in the accompanying table. The persons examined consisted of two groups, both highly selected in that they attended a normal school or earned their living under fairly competitive conditions; this probably explains the relatively low percentage of persons shown to have onchocerciasis by skin sweats who had microfilariæ in the eye. Of the 55 with embryos in the aqueous humour these could be seen with an ophthalmoscope in 54, whereas with a slit lamp they were seen in only 35. In the solitary case diagnosed with the slit lamp alone, one embryo only was found, and it had attached itself to the posterior surface of the periphery of the cornea, outside the pupillary area.

COMMENTS

There is no doubt that, if a minute search were made in every case with the slit lamp, microfilariæ would be seen even more often than with an ophthalmoscope. Such a search is often precluded by fatigue and by lack of cooperation on the part of the patient. Therefore, when the microfilariæ are scanty, ophthalmoscopy offers a greater chance of success. In remote areas of Africa, where the disease is prevalent, the simplicity of the apparatus has obvious advantages; for the doctor

TABLE II—FREQUENCY OF MOTIONS IN 700 BOTTLE FED INFANTS

Month of age	No of infants in each frequency group								Total
	4 or more daily	3 daily	2 daily	1 daily	Every other day	Every 3rd day	Every 4th day	Less often	
1	24	13	32	18	2	0	0	0	89

7–9	2	7	71	57	0	0	0	0	137
10–12	1	4	28	51	1	0	0	0	85
									700

already becoming regular, and after six months most infants who were breast fed have one or two motions a day Of the 16 infants in the breast fed series who missed four days or more, 9 usually went every five days, 1 every six, 4 every seven, 1 about eight, and 1 child missed twelve days without disturbance (table I) These last figures, depending as they do on mother's recollections over the previous weeks, can only be taken as approximate

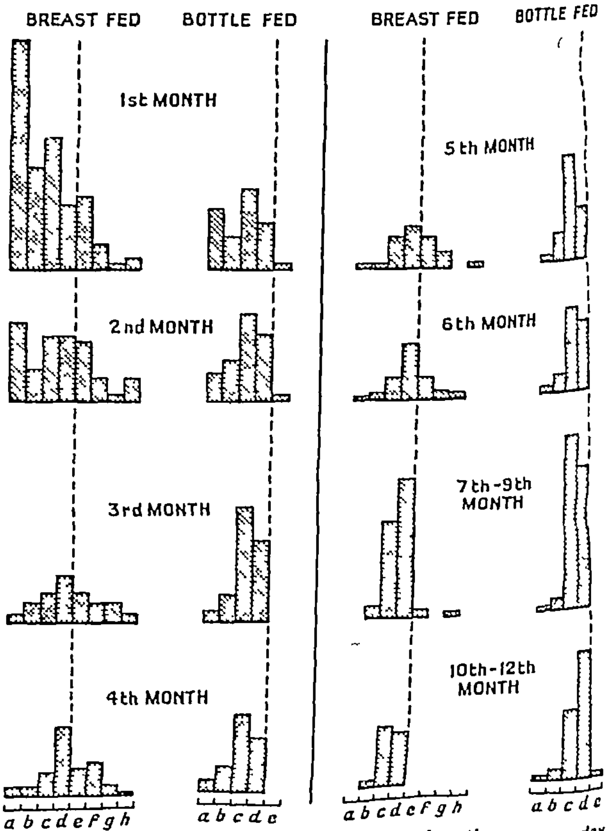
The bottle fed infants show a completely different picture (table II) Frequency in the first month does not appear to be so definite, but it is extremely rare for a bottle fed child to miss a day (although bottle fed infants are more constipated than breast fed in the sense that their stools are harder) In fact in the first two months only 4 out of 179 did not have a motion daily, and 3 of these 4 had symptoms suggestive of pyloric stenosis It appears that if a bottle fed baby does not have a bowel movement daily an organic disorder should be suspected

DISCUSSION

The most important feature of these figures is that 41% of healthy breast fed babies in the third, fourth, and fifth months do not have daily motions (see figure) In the past this has been regarded as abnormal by parents and the medical profession, and even today is probably so considered by most people This being the case, the immediate reaction in the past has been to put the matter right Generations of physicians have discoursed upon the advisability of inculcating good habits at an early age, and potting has become ritual It needs no great imagination to prophesy the course of action of the mother of the breast fed child at ages three to five months, who pots her child three or more times a day, and finds that nothing happens for one or several days She uses purgatives, laxatives, suppositories, enemata, and her little finger This may be the starting point of the habitual use of purgatives, which became a weekly ritual in Victorian times but was already known in B C 800 to occur—as Hindu writings show (Brown 1937)—and was practised not long ago in 95% of the working classes in America (Chodak Gregory 1934) Many physicians have regarded this abuse of purgatives as the cause of constipation—Hurst (1943) among them, in a discussion of dyschezia Is it possible that habitual constipation in the adult is thus the result of a misinterpretation of the physiology of the normal breast fed infant? If this be the case, constipation should be a diminishing disease, for breast feeding is diminishing not only in incidence but also in the length of time that the child is suckled (Gordon 1942) Furthermore, additions to the diet that make for regularity of bowel movement are introduced at a much earlier age than they were at three months by many pædiatricians, and even earlier in America To find out if a disease such as constipation is diminishing is a task that would receive no encouragement from statisticians, for it is neither notifiable nor yet does it appear on death certificates or necropsy reports

One thing is certain, the disease receives much less attention than it did in former years Arthur Keith in 1915 stated that it was a "condition which causes nearly as much suffering as even a great war" Who would make this statement today? For the years 1928–32 inclusive there was an annual average of 56 references to constipation in the *Quarterly Cumulus Index Medicus*, in 1946 there were 19, in 1947 only 15, and in 1949 in *Excerpta Medica* only 11 Nobody will suggest that the volume of medical literature generally has diminished correspondingly in these years Maybe the diminution of breast feeding, and the realisation that infrequency of motions in breast fed infants is normal, will eventually cause constipation to disappear as chlorosis has done Thus will end an unhappy era in therapeutics, wherein something normal has been made a disease, and vast amounts have been written about its imaginary causes Treatment, which varied from colectomy to psychotherapy, has included, not only roughage but a residue free diet (Smith 1930), not only increased fluids but diminished fluids (Oldfield 1943), and not only exercise but complete restriction of exercise achieved by three months in a spinal carriage (Graham Stewart 1928)!

If more talent and endeavour were spent on study of the normal infant, in say, well baby clinics, instead of being devoted to describing rare and exotic diseases, or to developing skilled operations such as colectomy for artificially promoted disorders, mankind would be



To the right of the dotted lines stools less often than once a day
a = 4 times a day or more
b = 3 times a day
c = twice a day
d = once daily
e = once every 2 days
f = once every 3 days
g = once every 4 days

out from both hilar regions to the lung periphery and largely confined to the mid zones (fig 4) The areas of increased density correspond with remarkable accuracy to the distribution of the radiation. The changes demonstrated on the film are roughly proportional to the dosage levels, being greatest where the dosage was highest

The patient's condition rapidly became worse, and she died within twenty four hours

Necropsy Findings—An elderly obese woman showing no external abnormality The pericardium was adherent externally to the mediastinal pleura but otherwise normal. The heart weighed 400 g and apart from right-sided dilatation, was normal No other cardiovascular abnormality was detected The right and left lungs weighed 1200 and 1125 g respectively, and both showed symmetrical contraction of the middle thirds spreading outwards from the hilum in a fan like manner (fig 5) These contracted areas were uniformly hard, greyish, airless, bloodless, and sharply demarcated from the apices and bases, which were œdematous and partially air-containing The larynx, trachea, and bronchial tree appeared normal, and no evidence of neoplastic disease was detected in the lung or in the tracheobronchial lymph glands The alimentary hepatic, biliary, lymphatic, urinary, endocrine, central nervous, and skeletal systems were normal

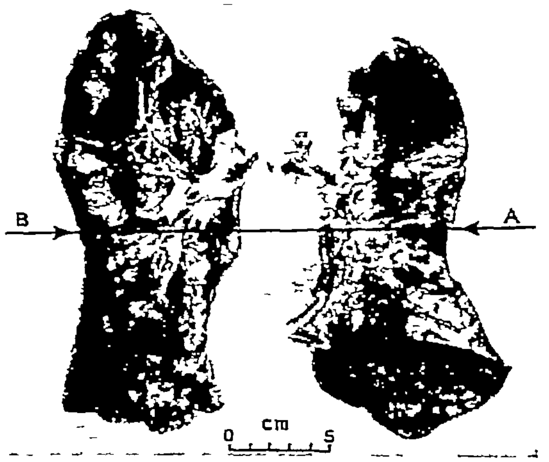

Fig 5—Half of each lung showing contraction of middle thirds.

Histology—Paraffin and frozen sections were examined from every lobe of the lung and from various levels of the bronchial tree Hæmatoxylin and eosin, van Gieson, and Weigert s stains for fibrous and elastic tissues, and Scharlach R for fat were used All sections from the consolidated areas of both lungs showed complete obliteration of the alveolar pattern by cellular avascular granulation tissue composed of fibroblasts and large swollen macrophages with faintly granular but mostly clear cytoplasm in about equal numbers (fig 6) The macrophages were of special interest because their appearance in paraffin sections first suggested the possibility of their containing fat, which was subsequently confirmed in frozen sections stained with Scharlach R The distribution of these lipoid macrophages was focal, the cells being arranged in clusters of up to 100 cells surrounded by fibroblasts with a scanty admixture of lipoid-containing cells The mean size of these lipoid foci was similar to that of normal alveoli and their distribution strongly suggested that they occupied the spaces of pre-existing alveoli which the presence of fragmented elastic tissue in the periphery tended to confirm. The bronchial epithelium appeared normal, though the lumen contained a few lipoid macrophages The fat present was mostly intracellular and varied from a few fine granules to large globules which occupied most of the cytoplasm distending the cell envelope and obscuring the nucleus of the macrophage (fig 7) The fat was anisotropic, rotating polarised light A minority of the lipoid cells also contained granules of carbon thus establishing their phagocytic nature

The apices and bases of both lungs showed œdema only

No unequivocal evidence of carcinoma was detected in any of the numerous sections of lung Sections of the heart kidneys, spleen, and lymph glands did not show any abnormality

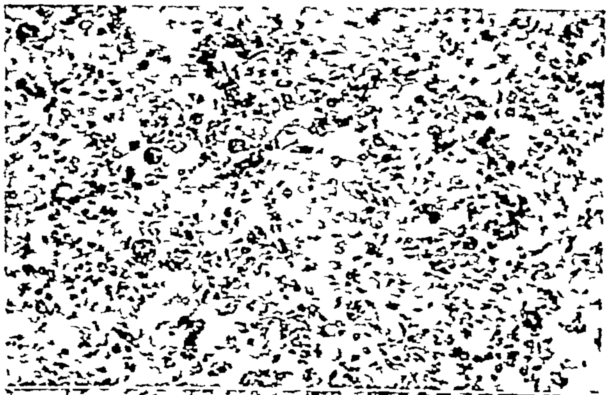
Anatomical diagnosis—Lipoid pneumonia following radiotherapy for carcinoma of the lung

DISCUSSION

The clinical picture of breathlessness, chest pain, and sometimes severe cough following some weeks or months after deep X ray therapy to the chest has already been noted many times, particularly in the United States (Groover et al. 1923, Warren and Spencer 1940, Fried and Goldberg 1940, Widmann 1942, Leach et al. 1942, Alexander 1944) and has previously been described as irradiation pneumonitis or irradiation pulmonary fibrosis In many patients the disease does not run such a severe or fatal course as in the case recorded here

The mechanism of symptom production has been studied in these cases by Leach (1943), who ascribes the dyspnœa, which is such a prominent feature, partly to the fibrosis, with compensatory emphysema of the unaffected lung, partly to a variable amount of fixation of the chest wall and partly to over-irritability of the Hering Brewer reflex In our case, owing to the patient's grave condition, studies of abnormal physiology were impracticable.

Pathology—The most conspicuous feature of the pulmonary consolidation was the intracellular lipoid, which was confined to the areas of both lungs which had been irradiated and which corresponded to the extent of the opacity shown by X rays Inhalation of fatty material was excluded, so one must assume that the lipoid was endogenous The demonstrable fat may then have been due to phanerosis and unmasking of lipoid substances normally present in pulmonary parenchyma and carcinoma, or to infiltration into injured cells rendered incapable of metabolising it The presence of anisotropic fat capable of rotating polarised light identified it as cholesterol esters, which are normal constituents of all cells It therefore seems that the fatty change was mainly, if not wholly, due to a degeneration liberating lipoid which was subsequently phagocytosed by macrophages, which accumulated in the alveolar



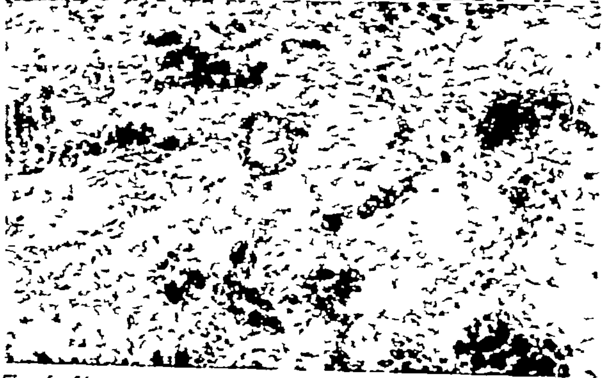


Fig 6—Above section of consolidated lung showing numerous macrophages filled with lipoid. (Hæmatoxylin and eosin.)
Fig 7—Below the same stained with Scharlach R., showing distribution of fat. (Both figs × 110)

in such regions it provides a rapid means of diagnosing ocular involvement in the earliest stages

Certain limitations must be considered When the media are so opaque that the red reflex is abolished, microfilariæ cannot be seen by ophthalmoscopy Such conditions as cataract and plastic iritis occur in advanced onchocerciasis and give rise to gross opacities, at this stage, in endemic areas, the diagnosis can usually be made on clinical grounds, confirmed if necessary by conjunctival snipping When infestation of the eye is heavy, the pupils often do not dilate with mydriatics, in these cases the microfilariæ are usually sufficiently numerous to be seen with the smaller field available

For surveys of large numbers of people and for the preliminary selection of cases, ophthalmoscopy has considerable advantages For a more minute examination of the eye, however, it does not take the place of the slit lamp

I wish to acknowledge the advice and assistance of Dr M. H Hughes, who has made clinical and laboratory investigations of most of the cases, and with whom I hope to elaborate the findings later My thanks are due to Dr R L Cheverton, director of medical services, Gold Coast, for permission to publish this report

LIPOID PNEUMONIA (NON-INHALATION) IN CARCINOMA OF THE LUNG TREATED BY RADIOTHERAPY

S J DE NAVASQUEZ
M D Lond
READER IN PATHOLOGY IN THE UNIVERSITY OF LONDON

J R TROUNCE
M D Lond, M R C P
MEDICAL REGISTRAR, GUY'S HOSPITAL, LONDON

A B WAYTE
M B Lond, D M R E
ASSISTANT SURGEON, RADIOTHERAPY DEPARTMENT GUY'S HOSPITAL, LONDON

LIPOID pneumonia is usually due to the inhalation of mineral or vegetable oil which irritates the pulmonary epithelium, causing fibrosis (Pinkerton 1928, Paterson 1938) Lipoid pneumonia arising without the inhalation of such oil has not yet been reported, and, although fibrosis in the lungs after irradiation has been fully described (Warren and Spencer 1940, Widmann 1942), the possibility of lipoid pneumonia resulting from irradiation seems to have been overlooked In the case described below lipoid consolidation of the lung was found after a pulmonary carcinoma had been treated by radiotherapy

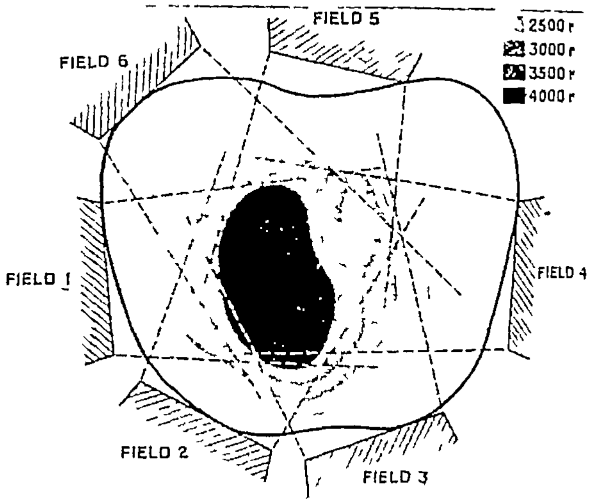

Fig 2—Fields of entry and dose distribution at level of tumour (A-B in fig 5)

CASE RECORD

A woman, aged 56, was admitted to Guy's Hospital under Dr Douthwaite in June, 1949, with two months' history of pain in the right upper chest with breathlessness and cough

On examination she had partial collapse of the right upper lobe, with a rounded mass in the right tracheobronchial angle (fig 1) Bronchoscopy showed that the right upper lobe bronchus was filled with new growth, which on section proved to be anaplastic oat-celled carcinoma

Treatment—She was given a course of deep X ray therapy in July, 1949 Deep irradiation at 215 kV with Thoræus I filtration and a half value layer in copper of 1 85 mm was used Six fields of entry, each 10 × 10 cm, were arranged round the chest (fig 2) Two fields were treated each day with a surface dose of 350 r, a total dose to each field of 2800 r being given in twenty eight days. This gave an aggregate tumour dose of about 4000 r units Fig 2 shows the approximtae dosage distribution within the thorax at the level of the tumour

Procaine penicillin 300,000 units was given daily throughout the course of radiotherapy in an attempt to control secondary infection and minimise the risk of lung gangrene

Progress—The patient's condition improved and fig 3 shows the radiological appearances ten weeks after the course of radiotherapy At the beginning of October, 1949, however, she again noticed increasing breathlessness, and this rapidly became worse She developed pain in the left side of her chest and was readmitted to Guy's in November, 1949

On readmission she was extremely dyspnœic and distressed Her temperature was 97°F, but her respirations 40 per minute Examination of the chest showed some impaired resonance at both bases, with harsh rhonchi and with a left-sided pleural rub Radiography revealed fairly dense shadows spreading

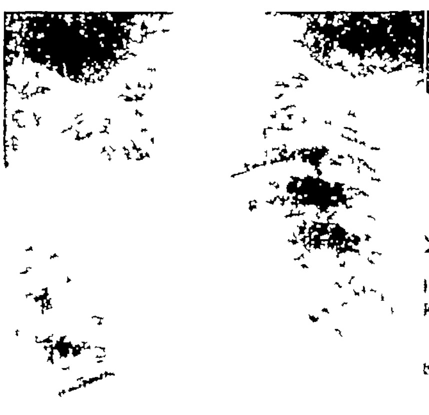

Fig 1—Radiograph showing opacity in right tracheobronchial angle with collapse of right upper lobe

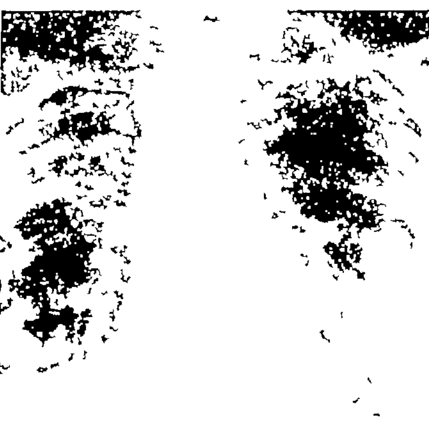

Fig 3—Radiograph ten weeks after radiotherapy, showing almost complete *disappearance* of shadows

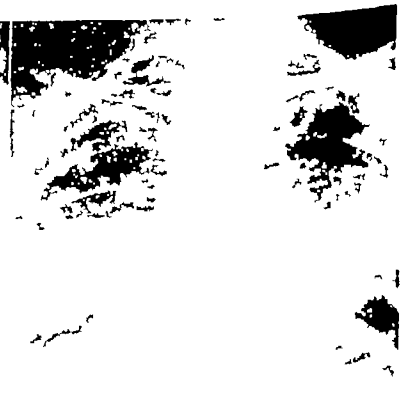

Fig 4—Radiograph ten weeks after that shown in fig 3 showing bilateral symmetrical shadows in middle thirds *of lungs* corresponding to areas irradiated.

CHANGES IN THE CEREBROSPINAL FLUID AFTER PNEUMO-ENCEPHALOGRAPHY

EDWIN R BICKERSTAFF
M.D Birm. M.R C.P
SENIOR REGISTRAR, DEPARTMENT OF NEUROLOGY, UNITED BIRMINGHAM HOSPITALS

In an earlier paper (Bickerstaff 1950) I reported changes in the cerebrospinal fluid (C.S.F) during pneumo-encephalography in 68 cases, and discussed the difficulties in finding an entirely satisfactory explanation for the mononuclear pleocytosis observed. These difficulties have not been resolved, though the number of cases examined in this way is now over 100

As most of the earlier workers on this subject (Hermann 1922, Weigeldt 1922, von Thurzo and Nagy 1923, Cestan and Riser 1924, Friedman et al. 1928, Jacobi 1930, Grant 1932, Eley and Vogt 1932, Kryspin-Exner 1932, Liberson 1933, von Storch 1936, Aird 1937, Newman 1937, Schwab and von Storch 1937, Levinson et al. 1939) had made their analyses on small numbers of cases in the hours or days following the pneumo-encephalography, and had recorded an almost exclusively polymorphonuclear pleocytosis, it was decided to re examine the C S.F in a large number of cases at carefully measured intervals following the first introduction of air, so as to compare these changes with those which take place during pneumo-encephalography, and to try to discover when the alteration in the type of cellular reaction took place

MATERIAL AND METHODS

The investigation was made pari passu with the routine work of this department A standard technique—alternate replacement of 5 ml. of C.S.F by the same amount of air—was used on each patient, and 80–100 ml. of air was introduced.

In 62 patients 3 ml. of C.S.F was removed at a second lumbar puncture done from 1 hour to 10 days after the first introduction of air, and the cells were counted within an hour

RESULTS

The cell counts are recorded in fig 1 An obvious difficulty in comparing figures is that each reading is taken from a different patient An attempt was made to examine at least two patients at each interval of time, and it was found that the same wide individual variations took place as were observed during pneumo encephalography (Bickerstaff 1950)

The cell count continued to rise after the introduction of air had been stopped, but only slightly for 2½–3 hours, after which it rose rapidly until 8–14 hours after pneumo-encephalography Very high figures were sometimes obtained—e.g , 3776 cells at 8 hours, 2560 cells at 9 hours, and 2840 cells at 14 hours The count thereafter began to fall, the rate varying from case to case but not reaching normal for at least 5 days

Fig 2 shows the average proportion of polymorphonuclear cells at different times after pneumo encephalography, and, whereas during pneumo encephalography the pleocytosis had been almost entirely mononuclear, polymorphs now appeared in increasing numbers until by 6 hours they represented 90–97% of the total count, and remained in this proportion for a further 12 hours. Mononuclear cells then gradually began to reappear, but the polymorphs did not entirely disappear until 96 hours

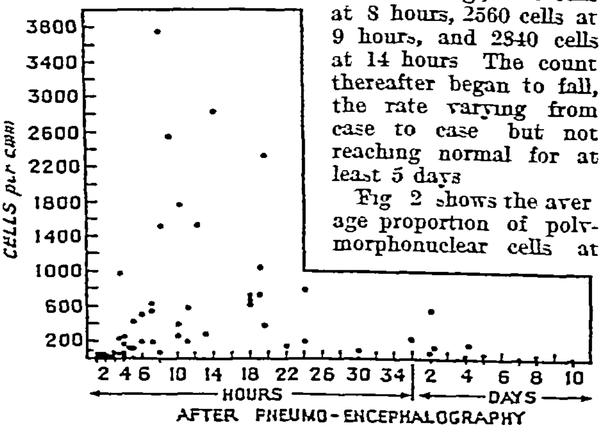

Fig. 1—Pleocytosis following pneumo-encephalography

The period of greatest subjective discomfort corresponded to the period of greatest polymorphonuclear reaction but did not necessarily bear any relation to the magnitude of the total cell count Patients with less than 200 cells per c mm sometimes suffered more severely than those with more than 2000 cells per c mm at the same interval after pneumo encephalography

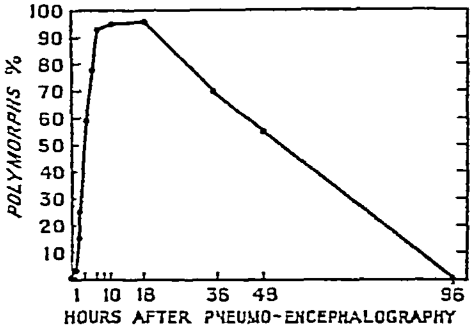

Fig 2—Proportion of polymorphs at different intervals after pneumo-encephalography

The biochemical changes were almost confined to the protein fractions The amount of sugar was either unchanged or increased by a few milligrammes at the height of the reaction The increase in protein, which had been found to follow the initial sharp fall during pneumo-encephalography, continued rather more rapidly, and readings of 75–100 mg were obtained at 2 or 3 hours and, with numerous individual variations, remained of this order until 22–24 hours, when they gradually fell, normal figures not being reached for 5 days There was not necessarily any direct relation between the amount of protein and the height of the cell count, and it remained raised in some cases after the cell count had begun to fall.

The tests for globulin became positive within 2 hours of the start and remained so until 24–36 hours

The diagnosis, the use of air or oxygen, time taken by pneumo-encephalography, and the height of the initial cell count did not influence the reaction, which appeared to depend on the length of time between the first introduction of air and the second examination of C.S.F

DISCUSSION

This investigation has shown that two distinct types of pleocytosis arise in the C.S.F in relation to pneumo-encephalography The first is seen during the actual procedure, it starts within the first few minutes and figures as high as 252 cells per c.mm may be reached in as short a period as 20 minutes It is almost entirely mononuclear, the magnitude of the rise being influenced by the height of the initial cell-count The second begins about 2½–3 hours after the first introduction of air, is more dramatic, is almost exclusively polymorphonuclear, and depends for its degree on the length of time before the fluid is re-examined, the greatest reaction being at 8–14 hours Mononuclears then reappear, but the C.S.F is neither cytologically nor biochemically normal for at least 5 days If different quantities of air are used, the cellular reaction is said to be proportional to the quantity of air (Schwab and von Storch 1937)

The pleocytosis after pneumo-encephalography is not so difficult to explain as the pleocytosis during pneumo-encephalography The later reaction is typical of an spaces and produced pneumonic consolidation The pneumonic consolidation was like that seen in lipoid pneumonia due to inhalation of oil, but differs both in the nature of the fat and in its pathogenesis

Studies are in progress to elucidate the mechanism of this phenomenon and its possible implications So far four consecutive examples of carcinoma of the lung which have not been irradiated have all shown the changes of lipoid pneumonia in the lobe affected by the tumour

SUMMARY

A case of primary carcinoma of the lung successfully treated by radiotherapy showed pneumonic consolidation due to fatty deposits (lipoid pneumonia) in the areas irradiated

Four consecutive examples of carcinoma of the lung which have not been irradiated have all shown similar changes

The fatty change is thought to be due to degeneration of the carcinoma and of the adjacent lung parenchyma, which is accelerated by deep radiotherapy

We are grateful to Dr A H Douthwaite for permission to publish this case

NEUROMUSCULAR INCOÖRDINATION OF SWALLOWING IN THE NEWBORN

J C Macaulay
M.D Lond, M R C P, D C H
FORMERLY HOUSE PHYSICIAN, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET, LONDON

Success in the surgical treatment of congenital œsophageal atresia depends largely on early diagnosis Belsey and Donnison (1950), Donnelly (1950), Ladd (1944), and Ladd and Swenson (1947) have emphasised this and have described the clinical picture But a superficially similar syndrome, unassociated with gross anatomical defect, has not been described, and this should be considered in the differential diagnosis of œsophageal atresia or stenosis, as the following case shows

CASE RECORD

A full term illegitimate baby of healthy parents was delivered, under chloroform anæsthesia, with forceps, because of delay in the second stage of labour He weighed 7 lb 6 oz His colour was good, but there was excess of mucus in the upper respiratory passages At the first and all subsequent feeds in the maternity home he became cyanosed and 'bubbly," and vomited frequently He was treated in an oxygen tent with penicillin and sulphadiazine, but did not improve A Wassermann reaction was negative

On admission at the age of 10 days, to the Hospital for Sick Children, Great Ormond Street, under the care of Dr Wilfrid Sheldon, his weight was 7 lb 3 oz, temperature 98 6°F, pulse rate 132, and respirations 36 per min. There was moderate cyanosis The upper respiratory passages contained an excess of mucus, and breathing was irregular and rattling The cry was weak There was moderate indrawing of the lower intercostal spaces and suprasternal notch on inspiration The percussion note was resonant, and the breath sounds were vesicular, with many rhonchi and moist sounds throughout the chest, varying but not disappearing after coughing The heart sounds were normal No abnormality was noted in the abdomen. Reflexes and fontanelle tension were normal, and there was no neck stiffness There was a well marked cephalhæmatoma in the left parietal region of an otherwise normally shaped head

Investigations—In view of the previous history the possibility of congenital œsophageal atresia was at first entertained, particularly when swallowed iodised oil reached the bronchi, suggesting a tracheo œsophageal fistula The infant's stool, however, indicated that some milk had passed down the alimentary tract Accordingly, a stomach tube was passed and found to enter the stomach easily Iodised oil was next swallowed by the infant under radioscopy, whereupon it was seen that when the oil reached the pharynx it was first inhaled into the trachea and almost immediately afterwards coughed back into the pharynx and swallowed down the œsophagus This suggested that the swallowing mechanism was defective, to the extent that the infant could not shut off the larynx during deglutition, and therefore fluid was as likely to enter the larynx and trachea as to slip past into the œsophagus

Treatment—The baby was nursed upright Feeds of expressed breast milk, 3 oz three hourly, were given through a stomach tube until the power of swallowing returned Penicillin 50,000 units was injected intramuscularly twelve-hourly for ten days

Progress—Physical signs in the chest persisted for ten days, and cyanosis during tube feeds for a week Small amounts of milk were regurgitated even after tube feeds for the first five days of treatment The baby remained afebrile and gained weight satisfactorily

Further radioscopy a week later (at the age of 17 days) showed that the swallowing defect persisted, but four days later he had improved enough to take feeds by mouth

Laryngoscopy (Mr James Crooks) two weeks after admission (at the age of 24 days) showed no anatomical deformity of the larynx or the epiglottis The movements of the cords were irregular and incoördinated the left moved well, and the right poorly

The child was discharged from hospital sucking and swallowing normally There was no further vomiting, and subsequent progress was uneventful When seen at the age of 10 months he was a normal healthy child weighing 22 lb and could crawl and stand His voice was normal, and breathing regular A barium swallow did not show anything abnormal

DISCUSSION

Transient disorders of swallowing may occur in new born babies as a result of prematurity or of obstruction of the respiratory passages by mucus Persistence of regurgitation and inhalation of feeds, with cyanosis and dyspnœa, are almost always associated with gross anatomical defects In addition to organic lesions of the œsophagus, congenital abnormalities of the medulla and extreme cases of amyotonia congenita may produce a similar picture

In the case described here there was no evidence of any of these However, the swallowing defect, the irregular breathing, the weak cry and the incoordinated movements of the larynx, with subsequent recovery, point to a reversible lesion of the medulla—a temporary partial bulbar palsy There was no clinical evidence of an intracranial hæmorrhage, but possibly there had been some bruising and œdema of the medulla which subsequently disappeared A more likely explanation is that there was an immaturity of the bulbar centres, with a consequent failure of coordination of swallowing, laryngeal movements, and breathing This is supported by some careful observations of Peiper (1942), who investigated the temporary swallowing and breathing disturbances of newborn babies and concluded that they were due to immaturity of the medullary centres

It is a pleasure to record my indebtedness to Dr Wilfrid Sheldon for advice and permission to publish, and to Mr James Crooks for the laryngoscopy report

ut had not then had dysentery or more than trivial ea

amination his temperature was 101°F , he was very over and below the right lower ribs, though the liver ould not actually be felt , his right diaphragm was le but not raised on fluoroscopic examination , and cell count showed 20,000 leucocytes per c mm (poly 85%) These findings left little doubt that the patient ppuration affecting the liver

ment and Progress —Since it seemed probable that ection was amœbic, a course of emetine gr 1 daily for days was begun on the third day The patient appeared rove a little at first, the pain and tenderness diminish out, as he continued to have a swinging temperature g 101°F, a course of procaine penicillin 300,000 units was begun on the thirteenth day and continued for days, though it had no striking effect Because of the ent fever and tenderness, on the fourteenth day a was inserted into the right tenth interspace in the illary line, and superficially a few ml. of thin dark pus was aspirated Further needling revealed no more The pus contained gram positive cocci on the smear moderate growth of coagulase positive *Staphylococcus* on culture (sensitivity to penicillin not determined) mperature and pain gradually lessened after the aspira nd from about the twentieth day onwards the patient l well He was discharged on the thirty fourth

ow up —Since then he has remained perfectly well, from a little effort dyspnœa In June, 1949, September, January, 1950, June 1950, and December, 1950, he was screened, and on each occasion the right diaphragm was completely paralysed but not raised

DISCUSSION

In the present case, although the diagnosis of suppurative hepatitis seemed virtually certain, there was doubt about the ætiology Since hepatitis of this kind, developing as an apparently isolated manifestation, is nearly always amœbic, it seemed likely that amœbiasis with secondary infection was responsible The fact that the patient had been free from bowel symptoms while serving in the tropics does not contradict this hypothesis

This case, and others seen for short periods after amœbic hepatitis during the war, suggest that paralysis of the diaphragm may not be particularly rare It is easy to overlook this condition, an ordinary chest radiograph often revealing nothing amiss , screening is necessary for its detection A most striking way to demonstrate the paralysis under the X ray screen is by asking the patient to sniff The sound side of the diaphragm then descends, and the paralysed side simultaneously ascends

It is interesting to speculate whether the paralysis is muscular or nervous , but it is difficult to answer this question without necropsy material

Medical Societies

ROYAL SOCIETY OF MEDICINE AND SOCIETY FOR ENDOCRINOLOGY

Adrenocorticotropic Hormone

E section of endocrinology of the Royal Society of cine and the Society for Endocrinology met on May nder the chairmanship of Dr F T G Prunty, to a symposium on A C T H

of F G YOUNG, F R S , discussed the evidence that are two pituitary gland principles that can affect drenal. These he called the " ascorbic acid factor " F), which is active in reducing the adrenal ascorbic content in hypophysectomised rats , and the enal-weight factor " (A W F), which increases the ht of the adrenal gland under similar conditions but not deplete its ascorbic acid The commercial lard preparation of A C T.H is rich in A A.F and ively poor in A W.F It is possible, however, to te a preparation of A C T H which is very rich in F and poor in A A F Although so far no preparation C T H has been entirely free of either factor, the of ascorbic acid depletion activity to adrenal ht activity in various preparations has varied from to 1 5000 or more, which is strongly in favour of existence of two separate principles If the pituitary d of a rat is removed, the adrenal gland atrophies ow one injects A W F , the adrenal gland shows a ral increase in size affecting all zones of the cortex distribution of lipoid granules, however, is normal ' large normal " picture is different from that uced by injections of A.A F , when the main result change in the distribution of lipoid granules (particu involving the zona fasciculata) If preparations C T H with mixed activity are stored, there is greater of A A.F than of A W F So far, the clinical applica- of the adrenal weight factor has not been elucidated here is now plenty of evidence that the activity of T H resides in a small peptide fraction of the main ein complex This peptide fraction can be removed acid hydrolysis as in the original experiments of Li his co workers or more simply by dialysation exchange column separation has shown clearly that T H consists mostly of a fast moving acid protein with small amounts of a slow moving basic peptide Hormone activity appears to reside entirely with the latter

Mr C J O R MORRIS, PH D , pointed out subsequently that A.W F as well as A A.F is separable by dialysis from the protein component It seems impossible that anything representing chemical combination in the ordinary stoicheiometric sense can exist between the protein and the peptide components The protein is, therefore, no more than a " carrier " which happens to be separated with the active principles Pituitary growth hormone, on the other hand, is not separable in this manner, and thus cannot be identical with A W.F , although commercial growth hormone usually contains A W.F Both A A.F and A W F can properly be spoken of as adrenal corticotropic hormone, and one must in future remember and allow for this dual nature of A C T H

METABOLIC REACTIONS

Dr PRUNTY reported some results of treatment of rheumatoid arthritis with A C T.H He showed that there is good correlation between the percentage fall in circulating eosinophils and the rise in urinary excretion of reducing steroids when A C T H is given, but no correlation when adrenaline is given The clinical activity of various batches of A C T H differs widely This is due partly to variation in the material, partly to variation in the responsiveness of the patient For any given batch and patient, the activity of A C T H is greatest when given by slow intravenous infusion, and least when given as a single daily dose Attempts to prolong the action of A C T.H by giving " depot " injections made up with polyvinylpyrrolidone have been unsuccessful

URINARY METABOLITES

Prof G F MARRIAN, F R S , discussed the methods of extraction and estimation of urinary steroids In the urine steroids occur free or conjugated Some conjugates are chloroform soluble, others are chloroform insoluble conjugates with glucuronic acid These are not normally extracted by current methods Methods of estimation of the conjugates involve acid hydrolysis, which itself may cause destruction of the free steroid Although standard methods of extraction and estimation acute irritation of the meninges, is accompanied by headache, vomiting, neck stiffness, and occasionally a very slight pyrexia, and is certainly due to the irritant properties of the air The same type of cytological change at the same intervals of time is present after ventriculography (Bickerstaff 1950) but is not so great as after pneumo encephalography, either because less air is used or because the increase in meningeal vascular permeability, thought to be produced by pneumo encephalography (Levinson et al 1939), is not present

Fleck and Stein (1951) are inclined to ascribe both stages of the pleocytosis to meningeal irritation If this is so, it is strange that the mononuclear pleocytosis does not occur during ventriculography

The return of the mononuclears from 20–24 hours onwards—still in much larger numbers than in normal C S F —finds a parallel in the work of Jackson (1949), who showed that, in experimental "aseptic hæmogenic meningitis," 24 hours after the introduction of the blood the perivascular spaces have become filled with lymphocytes, which then begin to reappear in the C S F Kubie and Schultz (1925) had noted similar results from artificially produced meningeal irritation, the initial polymorph response arising from the meninges, and the later mononuclear response from the perivascular spaces It seems likely that the same sequence of events occurs after pneumo encephalography, and it is noticeable that clinical signs of meningeal irritation are present during the period of polymorphonuclear reaction only It seems possible that the earliest changes of all—the mononuclear pleocytosis in the first few minutes—may also originate from the perivascular spaces

Two points of practical importance arise from this investigation First, no samples of C S F examined at any time from the first introduction of air to at least 5 days later can be considered representative of the usual composition of that patient's C S F , and, if further examination is required, it is wise to postpone it for 10 days or more

Secondly, there is, almost constantly, clear clinical evidence of meningeal irritation during the first 24 hours after pneumo encephalography This fact has been known for many years, indeed Bohn (1937) analysed 1000 cases in an attempt to discover some means of minimising the symptoms Nevertheless, at times it may be feared that infection has accidentally been introduced into the theca, a fear which may be increased when on examination of the C S F a brisk polymorph pleocytosis is discovered We have seen, however, that this is a constant phenomenon, there is very little rise of temperature, the sugar content of the fluid is, if anything, higher than normal, cultures are sterile, and the reaction settles spontaneously Re examination of the C S.F is not necessary, unless there is pyrexia, and the polymorph reaction is not an indication for the intrathecal introduction of antibiotics, unless pyrexia is accompanied by a low C S.F sugar level or a positive culture is obtained from the C S F

It has been impossible to forecast, as a result of this investigation, which patients are likely to have severe reactions, but it has been a most striking fact that those who underwent pneumo encephalography under general anæsthesia experienced very much less subjective discomfort in the following 24 hours, even though the cytological reaction was considerable

One of the remarkable features of this investigation has been the individual variations in cellular response both during and after pneumo encephalography, though a constant technique was used When one considers how differently different people may react to the same irritant stimulus, it is easy to understand the variations in mode of onset of such conditions as bacterial meningitis or poliomyelitis, when so many modifying factors may be at work

In conclusion it is repeated that no diagnostic significance can be attached to any of the different results, the same type of reaction with the same variations occurring in neurologically normal patients as in those with gross organic disease

SUMMARY

The cytology and biochemistry of the C S F was studied in 62 cases at intervals from 1 hour to 10 days after the start of pneumo encephalography

A brisk polymorph pleocytosis began at 2½–3 hours, reached a maximum at 8–14 hours, and did not return to normal for at least 5 days

The C S.F protein level rose steadily, reaching 100 mg per 100 ml after 3 hours and remaining at this level until 22–24 hours

The nature of the reaction and the practical applications of this knowledge are discussed

The ready coöperation of Dr J Rounthwaite, Dr C Woods, and Dr M Wilson, resident clinical pathologists at the Queen Elizabeth Hospital, who counted the cells, often at very inconvenient hours, is gratefully acknowledged, as is the help given successively by the house physicians to the neurological unit, and the permission granted by Prof. P C P Cloake and Dr G S Hall to make these investigations on their patients

SUPPURATIVE HEPATITIS AND DIAPHRAGMATIC PARALYSIS

JOHN W TODD
M D Lond , M R C P
CONSULTANT PHYSICIAN, FARNHAM HOSPITAL, SURREY

IT has been widely recognised for many years that amœbic hepatitis can paralyse the diaphragm Ochsner et al (1938), for example, say "The characteristic roentgenological changes are elevation and immobility of the diaphragm, usually the right" It is also well known that the diaphragm does not recover as quickly as does the liver In the India Burma theatre during the late war it was often observed that many soldiers who had apparently fully recovered from amœbic hepatitis continued to have complete paralysis, and often considerable elevation, of the right side of the diaphragm during the remainder of their stay in hospital But I have only been able to find one reference to this matter in published reports—Isaac (1945) says "It will be found that, while clinical response to specific treatment may be dramatic, the X ray signs will be much slower in returning to normal" No one seems to have followed cases to determine how long the diaphragmatic paralysis persists This case record may therefore be of interest

CASE RECORD

A man, aged 23 was admitted to Farnham Hospital in February, 1949, with ten days' history of pain in the right side, fever, and malaise He had been in the Royal Navy and had served for eighteen months in the Far East until May, 3)

that œstrogens stimulate adrenal
ereas androgens inhibit it, probably

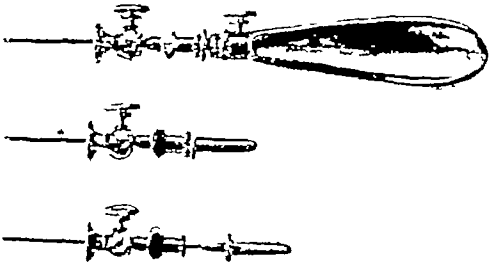
UNIVERSAL NEEDLE FOR BONE-MARROW ASPIRATION

ONE-MARROW aspiration needles are now an essential
t of the clinical pathologist's equipment The needles
uld meet the following requirements

) An adjustable guard, allowing for use in adults, a
dle length of not less than 2 5 cm
) As short a distance as possible between the needle point
syringe fitting so that the success of a puncture can be
ified quickly and marrow for films will enter the syringe
idly
3) A handle, to ensure steadiness and ease in the rotatory
vement usually employed in piercing the bone , a handle
specially helpful when piercing dense bone and the iliac
st
4) A variety of needles, all adaptable to the one handle,
use in adults children, or infants and allowing a narrower
dle than usual to be used on adults when it is likely that
ellular marrow will be entered—e g , in pernicious anæmia,
kæmias and certain neoplastic deposits



(5) The instrument must be sturdy , easily cleaned, re assembled, and sterilised , and conveniently transportable

After using the usual British, American, and Continental patterns I have not found one to fulfil all these requirements, but following the satisfactory use, some years ago, of the "Gimson" needle for bone-marrow transfusions in infants, my senior technologist and I have designed a new type of marrow-aspiration instrument which incorporates all the requirements (see figure) The main features are three needles, sizes 16, 17, and 18 S W G , *each of which has its own stylet, the strength*ened end of which will fit into a common handle, where it is held firmly in place with a side screw. When the marrow cavity is entered, the stylet, still fixed in the handle, is withdrawn and a 'Record' fitting syringe is attached to the top of the needle The reason for choosing these three needle sizes is that 16 S W G is the usual adult Salah type and 17 and 18 S W G, have been found suitable for children and infants The needle lengths are 3 5 cm. for the 16 S W G and 3 25 cm for the 17 and 18 S W G , and each is adjustable with a guard with a convex presenting surface

The instrument has been tried out extensively in the three sites usually chosen for marrow aspiration—sternum, iliac crest, and vertebral spine—and has been found very satisfactory From the patient's aspect it occasions the minimum of discomfort and "suction pain,' *and the operator, especially the less experienced*, finds it safe and easy to manipulate in obtaining an adequate marrow sample The handle and three needles rest conveniently in a 7¾ × 1½ in boiling-tube for sterilisation and transportation

The instrument is made by Messrs S J Owen of 35, Northampton Square, London, E C 1, under the style of the "H-H [Hill-Howe] Universal Bone-marrow Aspiration Needle"

Reviews of Books

Progress in Biophysics and Biophysical Chemistry

Editors J A V BUTLER, Chester Beatty Research Institute, Royal Cancer Hospital London , J T RANDALL, F.R.S , Wheatstone professor of physics in the University of London at King's College London Butterworth Springer 1950 Pp 279 50s

BIOCHEMISTRY we know, biophysics we know, and physical biochemistry we have heard of Is biophysical chemistry identical with the last-named, or is it a new product of the hybridisation of the sciences? If both terms refer to the application of physical chemistry to living, or sometime living, matter, it is unfair to couple the 'bio" with either ' physics" or "chemistry" "Physicochemical biology" is a possible solution. As further complication, J F Loutit's article on the Tolerance of Man for Radioactive Isotopes, though it comes from a radiobiological research unit, is clearly concerned with radiopharmacology and radiotoxicology However, nomenclature is the least of isotopic horrors, and Dr Loutit dilates amusingly on our exiguous knowledge of the tolerance dose of radium The catholicity of biophysics and ' biophysical chemistry" is shown by the circumstance that the articles come from laboratories devoted to colloid science, textile physics, physical chemistry, cell metabolism, cytology, radiobiology, medicine, and zoology All of these except one are in England

H Gutfreund contributes a usefully critical discussion of the measurement and results of measurement of the molecular constants of proteins paying particular attention to osmotic pressure The determination of the size and shape of protein molecules by measurements of the scattering of visible light and X rays is dealt with by G Oster K M. Rudall gives an enthusiastic account of the results and current interpretation of X ray studies of fibrous proteins, polysaccharides and polynucleotides M G M Pryor approaches the problem of muscular contraction from a different angle He leads through a thermodynamic treatment of the stretching of rubber and plastics, and model experiments with tendon, to the ' kinetic hypothesis in which muscle contraction is regarded as resulting may give reliable comparative results, they measure only a small fraction of the total steroid excretion Preliminary treatment of urine extracts with β glucuronidase causes non destructive hydrolysis of fractions previously unestimated, and the yield is increased as much as thirtyfold Much of the work done on urinary excretion of adrenal steroids must be regarded as empiric since it has not taken into account this large glucuronide conjugated fraction Preliminary results with the new technique show that all the steroid fractions estimated appear to come from the adrenal gland Furthermore, excretion of all fractions is increased in patients given A C T H

In addition, there is considerable doubt as to whether the type of steroid isolated is the only type secreted by the adrenal gland For example, seven 21 methyl steroids known to be of adrenal origin cannot be chemically assessed by current methods of estimation of urinary steroids Professor Marrian emphasised that there is as yet no method for the full quantitative analysis of all adrenal steroids and their metabolites If those workers who use present methods as a routine were to devote the same amount of time to developing improved methods, much greater progress would be made in this field

TISSUE REACTIONS

Prof G R Cameron, F.R S , spoke of the local tissue reactions during A C T H and 'Cortisone' therapy Most of the evidence suggests a local reduction of tissue œdema Pain, stiffness, and swelling of rheumatoid arthritis, for example, decreases during treatment, and this can be explained as the result of movement of œdema fluid from the affected area That this œdema removing effect is not of central origin is indicated by several findings, including the *local* relapse of tissues when hormones are withdrawn—e g , only those joints which have been affected by rheumatoid arthritis before treatment relapse afterwards Ebbing of œdema from diseased tissues was dramatically shown in serial photographs of nasal polyps treated with A C T H The effects of A C T H on the cellular reaction to injury, such as the healing of wounds, shows big species differences , in rats healing of experimental wounds is not inhibited, in guineapigs it is sometimes inhibited, and in rabbits it is always inhibited Nevertheless, all the evidence shows that the type of granulation tissue formed is qualitatively the same as normal granulation tissue It is the quantity and speed of its formation which is decreased

Professor Cameron reported some experiments on the alteration of capillary permeability by cortisone Rabbits that are injected intravenously with dyes of large molecular size retain the dye within the blood vessels If, however, the animal is injected with histamine or leucotaxin, or is roughly handled, the dye passes from the serum into the tissue spaces This effect is inhibited by cortisone He suggested that the local tissue action of cortisone may depend on the fact that it is surface active and may increase the resistance of the diseased cell surface to outside modifying influences Cortisone cannot, however, prevent the pulmonary œdema which follows the intravenous injection of ammonium compounds

In the subsequent discussion it was noted that these hormones had no effect on *normal* capillary permeability Dr E G L Bywaters said that the local effect of cortisone injected into rheumatoid granulation tissue is very little other than the production of a mild necrosis near the injected crystals This may well be due to the vehicle rather than the cortisone Dr G D Kersley mentioned that intra articular cortisone has been found to reduce the inflammatory reaction of a diseased joint to surgery He also pointed out that some of the effects of A C T H on capillary permeability may be due to contamination by posterior pituitary substances

ASSAY

Mr A S Parkes, D SC , F R S , mentioned some of the difficulties in the assay of A C T H In the intact animal any interference may cause the production of endogenous A C T H as part of a non specific response to stress This can be averted by removal of the pituitary, but for technical reasons only the rat can be successfully hypophysectomised as a routine Thus all work involving A C T H assay is for practical purposes limited to the rat, and this may have influenced previous experimental work In the hypophysectomised rat A C T H produces morphological, histological, and chemical changes, any of which might form the basis of an assay test Sayers and his co workers have used the depletion of ascorbic acid in the adrenal gland as their index of A C T H activity This test is sensitive and reliable and is now standard procedure Even so, several animals should be used for any one assay

A more elegant method of assay may be provided by perfusing hypophysectomised animals or isolated adrenal glands with A C T H and collecting the steroids secreted via a cannula in the adrenal vein There may also be a future for the assay of A C T H in intact animals after preliminary pituitary inhibition by large doses of desoxycorticosterone—a kind of physiological hypophysectomy Another test measures the effect of A C T H on the survival time of mice in a closed vessel This test depends on the fact that cortisone increases the resistance of mice to hypoxia A C T H is active in prolonging the survival of mice under these conditions. Unfortunately posterior pituitary extract has the same effect, and contamination of A C T H by this hormone has not been excluded

EFFECTS ON PERIPHERAL CIRCULATION

Dr J H Kellgren spoke of the reaction of the peripheral blood vessels to A C T H treatment In untreated rheumatoid arthritis the joints are warm and the fingers are cold Cold fingers also occur in scleroderma, in acrocyanosis, and in dermatomyositis This finger coldness is akin to that found in Raynaud's phenomenon, but greater in degree , a more or less continuous spasm of the arterioles in the fingers can only be relieved by considerable body heating However, if A C T H is given in these diseases there is flushing of the fingers and an increase in finger blood flow and temperature The increase is comparable to that noted in Raynaud's phenomenon treated by sympathectomy

In the subsequent discussion one speaker noted that where rheumatoid arthritis occurred only in one arm the increase in the peripheral circulation was greater in the fingers of the diseased arm than in those of the normal arm

PLASMA EXTRACTS

Miss Delphine Parrott reported experiments to determine the A C T H like activity of plasma extracts Circulating blood loses its A C T H like activity in a matter of minutes if stored without preservative, but if blood is taken straight into acetone reliable assays of the subsequent plasma extract can be made on hypophysectomised rats A C T H activity of the plasma is markedly increased in stress and in Cushing's syndrome, but is absent in Simmonds's disease The rapid decay of A C T H activity in stored blood suggests a circulating A C T H destroying enzyme

A C T H AND GONADS

Dr P M F Bishop quoted work suggesting that the gonads and their secretions have some relation to A C T H action A C T H cannot normally inhibit wound healing in adrenalectomised animals But if luteinising hormone is first given to adrenalectomised animals the power of A C T H to inhibit wound healing is restored Furthermore,

ONDON SATURDAY, JUNE 2, 1951

Pneumoconiosis in Coalminers

agree that the high incidence of pneumoconiosis outh Wales coalminers constitutes a major em of preventive medicine and engineering ons differ, however, about the emphasis to be d on the various methods of protection Broadly ing, some authorities would concentrate on the ression and control of dust, while others favour dic medical examination It is clear that if suppression in the mines were adequate there d be no need for periodic medical examinations ed, the latter method, by which a miner can be n out of a dusty job when he has developed an stage of pneumoconiosis, is not prevention at it may mitigate, but does not prevent, the ts of dusty conditions In so far as it does gate them it is a valuable measure But there is al danger that, if too much emphasis is placed periodic medical examinations, the primary need dust suppression and control will be ignored

he case for compulsory periodic examination of lminers is well stated by members of the Pneumoiosis Research Unit of the Medical Research ncil. Thus Dr CHARLES FLETCHER, director of unit, said in 1948 that "the sincerity of the ustry's and the Government's concern with the lth of coalminers will be judged by the speed and roughness with which such a system is instituted this country "[1], and in a recent article COCHRANE, ETCHER, GILSON, and HUGH JONES[2] again set out arguments in its favour The main advantages, they see them, are three In the first place it would ver the interval before safe dust levels are defined d effective dust suppression is achieved Secondly, would reveal the mines, seams, or districts where rly signs of the disease were still arising despite st suppression, which would enable the engineers take appropriate action. Thirdly, if periodic amination were combined with routine dust studies representative pits it should be possible in time determine the level of dustiness which does not ve rise to cases of pneumoconiosis Dr FLETCHER nd his colleagues also restate the evidence that adiographic changes can be detected before much arm has been done and that at this stage removal rom exposure to dangerous dust will prevent the rogressive massive fibrosis which they say is the ause of serious disability In the first instance a ilot scheme would be necessary, and it might well tart, they think, in South Wales, since there "the neumoconiosis panels are already used by the men s an irregular system of periodic examination." But n their opinion the scheme should be kept separate from compensation issues, and the pneumoconiosis panels should stick to "their statutory function of assessing disability and its cause" The National Joint Pneumoconiosis Committee, on the other hand, thinks that an experimental scheme would be more likely to succeed if it was not linked directly with the X-ray and dust-environmental surveys which are being carried out by or under the auspices of the Pneumoconiosis Research Unit of the Medical Research Council Quoting the Committee's opinion in Parliament,[3] Mr HAROLD NEAL, parliamentary secretary to the Ministry of Fuel and Power, said that facilities for X-ray examinations are already extensive and that every miner who claims benefit is radiographed In the two years ended last December, about 31,000 X-ray films were used, and 10,000 miners were diagnosed as having pneumoconiosis All of these, whether they left coal mining or not, have to report periodically for re-examination by the pneumoconiosis medical board, and 'the increased confidence of the men in the advice of these Boards was shown by the fact that up to the end of 1950 about 5500 of the 10,000 cases diagnosed had remained at work in the industry" This confidence may be further enhanced by the new regulations, summarised on a later page, whereby the arrangements for men certified as having pneumoconiosis under the Workmen's Compensation Acts are brought into line with the arrangements for those certified under the more recent Industrial Injuries Act both groups, subject to initial and recurrent examination for fitness by a pneumoconiosis board, may now work in mines and may claim benefit for any worsening of their condition. Over many years the pneumoconiosis panels (formerly the silicosis and asbestosis medical board) have built up a considerable body of experience of industry and the pneumoconioses (not only in coal mining), and we should rather see their work and influence widened than narrowed by confining them more strictly to their "statutory" duties

MEIKLEJOHN,[4] with much knowledge of periodic medical examinations in this country and abroad, believes that the time is not yet ripe to establish a system for all coalminers In his John C Bridge lecture he suggested the advantages of such examinations, though theoretically attractive, are not manifest in practice The advantages usually mentioned are (1) reduction of pulmonary tuberculosis, (2) detection of early silicosis, (3) collection of evidence on conditions producing the disease, and (4) assistance in diagnosis by providing serial records As regards tuberculosis "as often as not the tuberculous workman is absent on the occasion of the medical board's visit and so escapes examination and suspension, no matter, for the incapacitating effects of the disease itself soon eliminate him from work" The examinations, says MEIKLEJOHN, have little value in providing evidence of conditions producing the disease because the necessary exposure is considerable, and usually men move, and working conditions change, too often This objection, however, is not wholly valid for coalmining, in which the conditions are fairly stable Early diagnosis of silicosis depends very largely on radiographic changes, and panels of experts may interpret technically satisfactory films with some accuracy (though unfortunately the standard of chest radiography is still not high enough) The early and consistent diagnosis of early simple pneumoconiosis in coalminers is much more difficult than the diagnosis from the liberation of a plasticiser (? adenosinetriphosphate) In a review entitled "Local Refractometry the Observation of Transparent Inhomogeneous Matter" J St L Philpot brings together methods used for observing inhomogeneities in one, two, and three dimensions, treating the observation of moving boundaries in solutions as well as techniques of microscopy One of the latter, phase contrast microscopy, is discussed by A F W Hughes in relation to biological research A Engström describes the use of soft X rays for the analysis of minute amounts of biological material, the density of cell structures as small as 1 μ in diameter can be measured and a number of chemical elements determined in the volume of a single mammalian cell Bioelectric potentials are discussed very thoroughly by E E Crane, who considers many things from the cell wall of an amœba to electric fishes which generate 6 kilowatts, he has a valuable section on bioelectric potentials in relation to secretory function

This volume of critical reviews represents an important pioneering effort on which editors and authors are to be congratulated Further volumes to cover other aspects of the subject are promised, and they will be welcome

Infant Feeding and Feeding Difficulties

P R Evans, M D, F R C P, director, department of child health, and children's physician, Guy's Hospital, physician, Hospital for Sick Children, Great Ormond Street, Ronald Mac Keith, M R C P, assistant children's physician, Guy's Hospital London J & A Churchill 1951 Pp 255 12*s* 6*d*

This book reminds one of Mrs Beeton Wherever one opens it and reads in it for a quarter of an hour, it is informative, interesting, and attractive to read On the other hand it is difficult to imagine anyone reading it through If he did so, he would not easily derive from it a coherent practice of infant management, as the authors in the preface claim he should This is because the material, though full and up to date, does not seem digested, nor entirely self-consistent, and sometimes there is no summing-up of the evidence This is the case in the very important matter of whether natural feeding is really superior to artificial The evidence of Grulee's figures is given, and also Stevenson's argument that extra vitamin A abolishes the difference, but no balance is struck Occasionally (as though to compensate) there is a sweeping ex-cathedra statement without a word of supporting evidence, such as "If the mother is a child, breast feeding is undesirable" No definition of a "child" or "undesirability" is given

Such defects are not very important if a book is used as a work of reference Among its merits from that point of view are a host of small practical details such as the size of the cup to use for children and how to shape a teaspoon for infant-feeding These show great experience of the job and an uncommon appreciation of the difference that "wrinkles" can make to the doing of it One must also commend such a passage as "An adequate food supply is not the only thing the baby needs to grow happily The baby grows by breathing, exercising, feeding and feeling He needs fresh air, food, warmth, stimulation and security, which a loving mother will provide"

Über den Blutfarbstoffwechsel gesunder Säuglinge und Kinder

Wilhelm Künzer Dozent an der Universität Würzburg Basle S Karger 1951 Pp 86 Sw Fr 11

This monograph deals with the fall of hæmoglobin during the first three months of postnatal life This fall has been attributed by different authors either to increased hæmolysis or to decreased regeneration of red cells Dr Künzer gives results of detailed studies of hæmoglobin levels, reticulocyte counts, blood-volume estimations, and quantitative estimations of urobilin and bilirubin in the fæces, and draws the conclusion that increased hæmolysis is responsible for the postnatal fall of hæmoglobin He attributes this to an increased vulnerability of fœtal hæmoglobin, which, as is well known, differs from the adult hæmoglobin in many ways Details of blood-pigment metabolism are discussed, and a useful method for the quantitative determination of bilirubin in the stools is described

The Chordates

Herbert W Rand, PH D, associate professor of emeritus, Harvard University London H K 1950 Pp 862 45*s*

This lively and encyclopædic account of all the e logy, histology, morphology, comparative an (including its history), classification, and vert zoology that a student needs to know for an ho degree is profusely illustrated, and there is a gen supply of bold type, standing out like traffic light guide him This is no tome of dry description, author gets quickly down to rock-bottom prin and builds up from them Moreover he writes in clear English, the proofs have evidently been very fully read, and the index is satisfactory, but there not seem to be a single reference to any other work ex under the illustrations (which all seem to be borro and in the account of the *history* of compara anatomy A paragraph *in the preface suggests* t this omission is deliberate, *because of the* diffic in indicating *appropriate collateral reading to* student

Design for Sanatoria

Report of the N A P T Architectural Committ London National Association for the Prevention Tuberculosis 1951 Pp 128 12*s* 6*d*

Three years ago the National Association for th Prevention of Tuberculosis appointed a special committe to discuss the design and construction of sanatoria an chest hospitals of the future This committee of seventee included five medical superintendents, one sanatorium matron, a consulting architect, and two consulting engineers, and it was advised by eighteen other specialists, including a radiologist, two pathologists, a pharmacist, a physiotherapist, three thoracic surgeons, one chest physician, and four clergymen. There may have been some ex patients among this galaxy of experts, but ex officio the patient was not represented. It is not surprising therefore that this volume, striving as it does with great success to reconcile the desiderata of all its contributors, should occasionally seem to overlook Absent Friends

The ideal sanatorium is envisaged as having 200-250 beds divided into wings, 'houses," or ward units of 30 beds, and as being destined to last for the next 30-50 years Many things are considered in detail the site and size of the sanatorium, the structure of its building, its windows, balconies, roofs, doors, fittings, heating, lighting, floor-covering, decoration and equipment of rooms, cleaning, garbage and sputum disposal, kitchen and food transport, dishwashing, laundry, chapel, and mortuary The layout is lavish, the pharmacists occupying 8 rooms, the pathologists 9 (though they may manage to jog along with 7, or even 6 if they can share their library with other bodies) Similarly surgeons, radiologists, physiotherapists, and occupational therapists all need a good deal of elbow room, and the administrative block must have offices to accommodate a clerical staff of twelve Some 80% of the patients, however, have a quarter of a bedroom each, and though there is a central hall for concerts and film shows, and an abutting library and quiet room (and if possible a separate television room), there is no mention of lounge common room, or small games department, or of any revolving shelter in the grounds whither a patient might repair for respite from his fellow men

Until large quantities of money and building materials become available, and large staffs, both nursing and domestic, can be coaxed into tuberculosis work this is likely to remain a sanatorium in the air Military hospitals can spring up almost overnight, and vast accommodation of one sort or another would be quickly forthcoming in the event of a savage epidemic of small pox, typhus, or some such *quick killing* disease, but towards tuberculosis we have been comparatively apathetic Why, it may be asked, not adapt existing buildings for the present emergency? A foreword warns us that this temptation should be resisted on grounds of running costs and efficiency Certainly nobody contemplating building a sanatorium can afford to miss reading this book, but who, having read it, could afford to build the sanatorium?

Fortunately for the schools, two new sources of help have appeared. In December, 1950, the American Medical Association established a foundation with an initial appropriation of $500,000 to help the medical schools, and last week, in New York, another organisation was formed for the same purpose. This organisation, the National Fund for Medical Education, is being sponsored by the medical profession, educational and scientific foundations, a group of university presidents, industry, agriculture, and organised labour, and its chairman is Mr. Herbert Hoover. Its objectives are to inform the public of the plight of the medical schools and to raise from private sources a minimum of $5 million annually for their benefit. The Fund will be helped by the foundation set up by the A.M.A., which has agreed to merge its funds with those of the new organisation. All money collected will go to the schools, because the costs of administration will be borne by twelve foundations.

PANIC IN THE STREETS

THE possibility that an atomic attack on a modern city might cause widespread panic is exercising official brains, and in this country a Home Office working party is pursuing inquiries, partly by means of questionnaires issued to the police about the estimated movements of population. From the U.S.A. comes an article[1] reviewing the causation and prevention of panic and measures for its control.

Panic, says this article, occurs when overmastering fear, especially of the unknown, causes a group to lose its sense of solidarity and to disintegrate into a disorganised mass of individuals, whose behaviour may be antisocial and lacking in the essentials for individual self-preservation. Contributory factors are those lowering morale—tension, insecurity, rumours, imitative behaviour due to heightened suggestibility, lack of previous information about the nature of the danger, and strong sensory stimuli such as noise. To these might well be added such physical factors as hunger, fatigue, exposure, and pain. Preventive measures should be based on organisation to maintain essential services: communications; police and fire; rescue, first aid, and medical; sanitation; welfare; civil defence, including anti-radiation or anti-chemical warfare; engineering and demolition; and transport, both for maintaining the foregoing and to effect any necessary evacuation of survivors. In general, the higher the standard of education and intelligence among a population, the less is the risk of panic reactions. Cantril et al.[2] in their investigation of the famous mass panic following the Orson Welles *Invasion from Mars* broadcast in 1938, found that college graduates were more resistant to the general alarm than people who had been educated at grammar school; even so, 28% of the panic-stricken sample interviewed were college graduates. Specific information beforehand about a possible danger would help people by removing the unknown element in their fears. Such information should be accompanied by allocation of active roles to members of the threatened community to give them a sense of increased solidarity. They should be warned about spreading rumours and told how to deal with them, and instructed in the various physical and mental reactions that acute stress may evoke, so that they may better understand and tolerate such reactions in themselves and their fellows. Methods of handling crowds, blocking routes of mass flight, and segregating panic reactors would be a matter for the civil authorities.

The American workers recommend that psychiatric casualties should be dealt with, as far as possible, without removing the patient from his family or group setting. The secondary gain of neurotic illness should be minimised and the suggestion of disability avoided. Screening of psychiatric casualties should be carried out at casualty-collecting points where sedation can be given and shock, exposure, and fatigue treated. Psychotherapy should be brief, consisting of reassurance, support, and exhortation; this should be enough for most patients, who would then be fit to return to the population. Others would need to be evacuated, preferably to hospitals not far removed, for more intensive psychiatric care. The detail in which the latter is discussed, and the comparatively ample facilities debated as makeshift measures, would bring a sardonic smile to the Asiatic face, for they call to mind MacCurdy's[3] remark that Westerners cannot face the prospect of misery: "Except in the coldest of winter months, in the absence of available buildings, adequately heated tents will constitute acceptable facilities. Folding canvas cots would be acceptable in lieu of beds."

For the average man, morale depends upon his feeling himself to be under the protection of some accustomed figure of authority, whether this be Providence, the Government, Mr. Herbert Morrison's signature on a passport, or merely the shadowy "They" whom he alternately reckons on and reviles. The solidarity of a group, according to Freud,[4] results from its members being identified with one another by virtue of their common emotional bonds with the "leader." If the leader or his surrogates are lost or demonstrably impotent to cope with the situation, the group falls to pieces and the individual feels atomised and abandoned. The external danger then becomes overwhelming because he is facing it in a state of agonising mental loneliness comparable only to the terror of a young child separated from his mother. That all the individual members of a group do not get into this state of panic is presumably because the more fortunate of us, even if physically sundered from our leader figures, feel enough self-confidence, through having taken them and their precepts into our moral being, to cope with whatever danger confronts us as we imagine what they would do ideally. Paradoxically, it appears that the essence of a true democracy is for each one of its citizens to be able to slap himself on the chest and exclaim, in the words of le Roi Soleil: "L'Etât, c'est Moi!"

PREVENTION OF TETANUS

TETANUS is not notifiable in England and Wales, but the General Register Office records that 48 males and 21 females died of the disease in 1948. Conybeare and Logan[5] have shown that the death-rate among males is now about half what it was during the years 1931–40, while the female death-rate has declined little. Of the 36 children who died from this cause between 1938 and 1947, 29 were under a month old; most of these infants were males. Three times as many fatal cases occur in rural areas as in Greater London and the large cities, and the east and south-west of the country suffer more than other regions.

Although the over-all risk of tetanus is small, the disease is so distressing and the mortality so high that the question of when to give antitetanic serum must constantly be faced. The decision usually depends on the extent, nature, and depth of injury; but Pratt[6] showed that of 56 Boston children who developed tetanus 80% had only minor injuries or superficial scratches. Unfortunately A.T.S. may cause serum sickness or severe hypersensitivity reactions, so the practitioner's dilemma in treating minor injuries may be very real. Since the of whom were vaccinated with B C G in 1935–37 A persistent high degree of tuberculin sensitivity was commoner among the unvaccinated than the vaccinated, but in certain areas the changes in skin sensitivity suggested that some of the vaccinated had undergone superimposed infection with virulent tubercle bacilli In one community the fluctuations and reversions from positive to negative were more common in both vaccinated and unvaccinated than in any of the other Agencies This waning of sensitivity was thought possibly to be related to climatic factors such as excessive sunlight, which might decrease the general reactivity of the skin In the U S A geographical variations in the pattern of tuberculin sensitivity have been observed before **Palmer** and his colleagues[7] noted that a low level of skin sensitivity was much more common in some of the southern States than elsewhere in the country, and they suggested that in these areas infection by acid fast bacilli other than the tubercle bacillus may account for some of the weak skin reactions to tuberculin It was in men from the south eastern States, too, that **Michael** and his colleagues[8] found among army personnel the highest incidence of sarcoidosis, in which tuberculin skin sensitivity is often low or absent

Annotations

MEDICAL DISCIPLINARY COMMITTEE

Doctors have observed an ethical code since the time of Hippocrates or even earlier In this country the professional corporations from their foundation maintained discipline among their members, in 1578, for instance, the Incorporation of Barber Surgeons of Edinburgh forbade Duncan Hunter to exercise any surgery or barbercraft in the burgh under penalty of ten pounds (Scots) because he had employed an unqualified assistant In 1858 the Medical Act set up the General Medical Council to regulate medical education and enforce professional discipline, and at first all members were doctors The council, in the exercise of its disciplinary powers, was criticised on occasions, and as a result of the Axham case in 1926[1] lay members were introduced But whatever its faults the Council has served as a model for other professional organisations

It had for some years been felt that to take up the time of a large body of senior professional men to hear every case was wasteful, and under the Medical Act of 1950 a small committee of the council becomes the "court" of the profession The Law Society also has a small committee for this purpose, but the origin of discipline in this profession is the courts, from which it derives the tradition of a small body The Pharmaceutical Society has a disciplinary body, and the Royal College of Veterinary Surgeons, which has exercised disciplinary powers over veterinary surgeons since 1849, adopted the practice of a small committee under the Veterinary Act of 1949

The General Medical Council now has two committees concerned with disciplinary business The Penal Cases Committee, made statutory under the new Act, is a "court of first instance" in that it decides whether there is a *prima facie* case to be dealt with by the Medical Disciplinary Committee A complaint may prove to be too trivial, or a doctor who has had a first conviction recorded against him in a court of law may not have to be brought before the Disciplinary Committee unless he commits a further offence The members of one committee may not be members of the other, except for the president, who presides over both The Medical Disciplinary Committee consists of 18 members Cases are heard by 9 members, with a quorum of 5, unless it appears to the president that "there are circumstances requiring the presence of a greater number of members of the committee", this procedure was adopted in one of the cases at last week's session which presented unusual features When 9 members are sitting 1 lay member and 2 direct representatives must be invited to attend In their deliberations the committee is assisted by a legal assessor An important difference between the new committee and the council under the old procedure is that the committee has the power to cause the oath to be administered—a power which it exercised in every instance at its first penal session The committee, like the council before it, is also responsible for striking dentists off the Dental Register Such cases are heard by the Dental Board, and if the board thinks that the dentist should have his name erased from the Register, a recommendation is made to the Medical Disciplinary Committee and may be challenged before that committee Possibly, when legislation is introduced to amend the Dental Acts the Medical Disciplinary Committee will no longer act in this way

One of the most celebrated cases against the General Medical Council, and the only one which went on appeal to the House of Lords, resulted in the ruling that the council had not made "due inquiry" because it refused to allow evidence not before the Divorce Court to be called The Medical Act, 1950, reverses the rule in the Spackman case Whether this will be an advantage to justice remains to be seen The chief criticism of the old procedure was that there was no appeal from an erasure Now any practitioner whose name is deleted from the Register may, under Section 20 of the 1950 Act, appeal to the Privy Council within twenty eight days

HELP FOR AMERICAN MEDICAL SCHOOLS

Medical schools in the United States are in serious financial difficulties As noted in our leading article last week, a committee set up by the Surgeon General of the U S Public Health Service has reported that, though research grants to medical schools almost quadrupled between 1941 and 1948, the funds for maintaining the schools themselves did not increase on anything like the same scale The inability of the schools to expand is one reason why only a third of the students who complete their premedical education can find places in them—and this at a time when, according to the Federal Government Reorganisation Commission,[1] the number of trained doctors is "woefully inadequate for the conduct of national defence, for the Federal hospitals, and for the needs of the people generally"

It is estimated that an additional $40 million a year is needed—$10 million for the public schools and $30 million for the private schools But, as the Surgeon General's committee points out, it is doubtful whether this extra money can be got from the existing sources

ADMINISTRATION OF DRUGS

HAZARDS AND PRECAUTIONS

W. TRILLWOOD
Ph.C.
CHIEF PHARMACIST, UNITED OXFORD HOSPITALS

IN handling drugs the nurse may be exposed to both unavoidable and avoidable risks.

As regards unavoidable risks, the strain on nursing staff has never been more intense; even in hospitals where there is no shortage of nurses, the intensity of work is maintained by the pressure of heavy waiting lists. Hospital authorities have repeatedly stated that in a general hospital taking acute cases the optimum bed-occupation is 85%; yet many hospitals are working at 90–95% and even higher levels. It does not seem to have been acknowledged that one possible source of errors is overwork.

Another risk is related to innovations in drug therapy. During the last decade the range of potent drugs in daily use has increased enormously. Ten years ago some of the potent drugs now in common use would have been rejected as too toxic; but new techniques of control have been evolved to make possible their use in therapeutics. There has, however, been no parallel evolution of safety precautions to protect the nurse from errors in administering these substances. Indeed, the nurse is at a particular disadvantage in that her knowledge of drugs and treatments is based on a syllabus outdated by at least fifteen years. She is, for example, required to have some knowledge of linseed poultices, cupping, blisters, and leeches; but officially she is not aware of the sulpha drugs and antibiotics. Nevertheless she is expected intelligently to administer these substances with whatever information she can gain from ward practice. In any event her training in materia medica is inadequate; and if she is to be kept abreast of developments the syllabus must be revised at short intervals. The nurse should, it seems, have a longer general course which would include the basic principles of prescription reading and of drug administration, storage, checking, control, and sources of information on the properties, dosage, and therapeutic effect of new drugs.

AVOIDABLE RISKS

Prescribing by Nurses.—There is a fairly widespread tendency for the hospital nurse to prescribe routine drugs. This is a practice for which she is not fitted; indeed, with certain drugs it is illegal. It would be wise to implement the standing order for ward sisters drawn up by the Royal College of Nursing which expressly states that the ward sister "shall on no account give medicines to patients without the written authority of the medical attendant."

Failure to Read a Label.—This is one of the richest sources of mishaps. Under this heading should be included the alteration of a label, or the re-labelling of a drug by the nurse; the administration of a drug from an unlabelled container; and the transfer of a drug into an unsuitable container (e.g., lysol into a lemonade bottle or, worse still, into a graduated medicine bottle). The dangers of these practices should be emphasised repeatedly, until as a routine the nurse reads, re-reads, and checks every drug label before and after use—until any container that is not labelled or is not clearly labelled, or whose contents are otherwise in doubt, is rejected or destroyed.

There is a special variant of this risk in the practice of measuring doses of drugs into a series of unlabelled gallipots or spoons. This procedure is usually carried out at the drug cupboard, wherever this happens to be. The nurse administering drugs is charged with a tray bearing the unlabelled gallipots or spoons, and is expected to remember which drug is for which patient, with no clue to the identity of the drugs apart from their colour and consistency. I suggest that the labelled medicine containers should be taken to the bedside and each drug measured, checked, and administered on the spot.

Administration of a Drug to the Wrong Patient.—This is fortunately rare, but the risk has to be seriously considered. Patients are impressed by the speed with which nurses learn to address them by name; and for day staff this knowledge is obviously the main safeguard; but for a night sister supervising several wards of sleeping or unconscious patients the safeguard is less certain. Name discs attached to the person of the patient would seem to be the only sure means of identification.

Failure of the Checking System.—This is the greatest source of potential danger. In his home the patient usually has direct access to the drugs prescribed for him; the drugs are dispensed in labelled containers so that, provided the patient can read and that he follows the directions, there is little risk of mishap. In hospital practice, however, the nurse intervenes as a third party. The law does not demand that any particular nurse—or indeed that any nurse at all—shall check another nurse before a drug is given. But it is a matter of common sense that the senior nurse available should check her colleague; and no nurse, however senior, should feel that her dignity is jeopardised in calling for a check.

In busy medical wards with many patients, some perhaps having several drugs at different intervals, it is difficult for the nurse to select the drugs to be given at any particular time. Usually this difficulty is overcome by means of a "medicine chart." The sister compiles a list of patients in her ward under time headings, and from the original prescription sheets she copies the name and dose of the drug prescribed. Thereafter this copy of the original documents becomes the chart by which all drugs are administered and checked. This procedure is extremely dangerous. First, a mistake in copying from the original prescription is perpetuated; indeed, when a fresh chart is prepared details are re-copied from the old one and any mistake is renewed. Then there is likely to be a time lag in copying a new prescription or in changing an existing prescription on the chart. In a busy medical ward this is very liable to happen, and most sisters are aware of the danger. In fact every sister questioned by me in an investigation in the Oxford region admitted freely that prescriptions were sometimes written or altered without her knowledge. To counter this risk several different systems are used; the most precarious is that which depends on the doctor telling the sister that he has made a change of drug or dosage. Neither the sister nor the doctor seems to be alive to the risk of forgetting to tell, or of not remembering what was told. One can conceive of an adverse laboratory report necessitating an immediate reduction in dosage of a potent drug; but because of a misunderstanding between nurse and doctor the change is not copied for some time on to the "medicine chart" and the patient thus continues on the higher dosage.

PLAN FOR IMPROVED CHECKING SYSTEM

In formulating a new method for avoiding these risks, it is axiomatic that the original prescription should be the focal point of every checking system; and that no drug whatever should be administered by a nurse without direct reference to the original prescription each time a dose is given. A prescription, like a cheque, is an order in writing, and as such it needs no verbal instruction before being honoured. But it is also an order to the pharmacist, who will require the original document to prepare the drug; and if, for this or other reasons, the prescription is not on the ward when it is required direct

1914–18 war few have doubted the prophylactic value of A.T.S., the disease may still arise even after adequate doses,[7] but this seems to be very rare. With massive infections of mice Taylor and Novak[8] found that local injection of procaine penicillin G was more effective than specific antitoxin in prophylaxis. The bacilli are penicillin sensitive and it may be possible to achieve adequate concentrations at the site of production of toxin, but this would not obviate the need for A.T.S. The main problem, however, is not the efficacy of A.T.S. as a temporary cover but to ensure that those most liable to the disease shall be protected. During the late war British troops were immunised with two doses of tetanus toxoid, and if wounded they received A.T.S. as soon as possible after the injury as possible; American wounded received a boosting dose of toxoid in place of antitoxin. There were very few cases of tetanus in either army. An effort to secure similar protection among certain groups of civilians is being made in several countries, but the practical difficulties are great. We have to remember that two doses of 1 ml. of toxoid are required, separated by an interval of at least six weeks, and that a third dose, 6–12 months later, should also be given. Severe reactions to toxoid are now very rare, and it can be given subcutaneously without causing a local reaction. In America, where toxoid is often combined with diphtheria prophylactic or pertussis vaccine, immunisation against tetanus is widely practised.

Bigler[9] immunised 300 children and infants during 1938–39, and he found that with two injections of toxoid protective levels of antitoxin were not always obtained. He recommends that a booster dose of toxoid should always be given no matter how short the interval between the initial injections and wounding. Detectable amounts of antitoxin were present in the blood serum of all immunised children ten years after inoculation, and the response to a boosting dose occurred within 7 days. There is little doubt that toxoid could prevent most, if not all, civilian cases of tetanus, and there certainly seems to be a case for offering it to school-children in rural areas, where the risk is greater than in the cities. Conybeare and Logan suggest that this could be done when they receive their boosting dose of diphtheria prophylactic on entry into school.

RETINAL CHANGES IN AORTIC COARCTATION

A SIGN that may help in the diagnosis of coarctation of the aorta has lately been described by Granstrom.[10] Of 40 patients with coarctation who were referred to him for routine fundus examination, 24 had increased tortuosity of the retinal arteries. This tortuosity was often widespread but sometimes it was confined to isolated sectors. In extreme instances it amounted to corkscrewing of the arterial loops, some of which were embedded in retinal tissue; in others it was less pronounced but "sufficient in degree to be characteristic." This abnormality was more usual in patients over the age of 25, and it was unaffected by operation for the coarctation. Associated changes in arterial calibre and at the arteriovenous crossings were at the most slight, and hæmorrhages and exudates were entirely absent. The veins (unlike those in congenital tortuosity of the retinal vessels) showed no undue tortuosity. Granstrom associates this sign with the generalised coiling of the arteries of the upper half of the body often found in coarctation. Since a certain amount of increased tortuosity is not uncommon in normal fundi it may be difficult to decide when the change is pathological. Of Granstrom's 24 cases in which the sign was regarded as present, only 7 were classed as having "marked cork-screw tortuosity," while 17 had "slight but unmistakable changes." In assessing the sign much will obviously rest with the eye of the beholder.

SICKNESS INSURANCE IN SWEDEN

SWEDEN was late among the European countries in adopting compulsory sickness insurance on a national scale. In August, 1947, however, a comprehensive scheme applying to virtually all Swedish residents passed through parliament. This was to have been brought into operation on July 1, 1951; but, owing to financial difficulties, parliament decided last December to postpone the date.

Under the scheme,[1] contributing members and their dependents are entitled to medical care with free choice of doctor and hospital. Remuneration of both general practitioners and specialists is based on a scale of fees for services rendered; 75% of these costs is borne by the insurance societies, and the remainder by the insured persons themselves. Doctors are not obliged, however, to restrict their fees to the amounts prescribed in the scale; they may charge, and the patients may pay, higher fees, but the patient is not entitled to recover from the insurance societies more than 75% of the fees on the official scale. The doctors receive mileage payments, and the expenses necessarily incurred by insured persons in travelling to receive medical treatment are reimbursed when the cost exceeds 3 crowns (there are $14^1/_2$ crowns to the pound sterling). The scheme provides a maternity benefit—a lump sum cash payment—and periodical cash payments to patients certified as incapable of work, the amount of the latter varying with the contributions paid. Sickness payments, however, are granted only to people whose annual earnings exceed 600 crowns. Others may insure for medical treatment only, and they pay a reduced contribution. Sickness payments are not payable during the first three days of incapacity. Medical supplies will be obtainable free or at reduced cost. The benefits of the scheme do not include such forms of treatment as massage, electrotherapy, or therapeutic gymnastics; but insured people may become entitled to these as supplementary benefits through the voluntary insurance system, to which the State grants subsidies equal to 20% of the contribution income. This voluntary system also provides supplementary sickness benefits in cash, but the total cash benefits of the compulsory and voluntary systems may in no case exceed the earnings of the insured person.

The scheme will be administered locally by the existing sickness insurance societies, which are to be reorganised. Each insured person is required to join a society in his district. The societies are supervised and directed by the National Control Council, but they have a considerable measure of local autonomy. The control council fixes the contributions payable to the insurance fund, and distributes the contribution income in due proportion among the societies. The total cost of the compulsory scheme in the first year of operation will, it is estimated, be 237 million crowns. The State will contribute 70% of this sum, the remainder being covered by the income from contributions. Special legislation is to be introduced for universal free provision of hospital treatment. Local authority hospitals will receive a State subsidy of 2 crowns per patient per day.

REMUNERATION OF GENERAL PRACTITIONERS

AT a whole day meeting on May 24, the General Medical Services Committee considered the latest proposals from the Ministry of Health for adjusting the remuneration of general practitioners in the National Health Service. The committee was not satisfied with these proposals, and it decided to send its observations to the Ministry, asking for an immediate reply.

GENERAL MEDICAL COUNCIL

As we reported last week, the presidential address by Prof David Campbell opened the session of the General Medical Council on May 22 The Medical Disciplinary Committee, the body which in future will hear penal cases under the Medical Act, 1950, sat for the first time for the hearing of such cases on May 24, but there remained some cases postponed or adjourned from previous sittings which the whole council heard on the first day, after taking dental disciplinary cases

POSTPONED JUDGMENTS

The council did not see fit to direct the Registrar to erase from the Register the names of the following practitioners in respect of whom judgment had been postponed for one year *Thomas Dunbar* registered as of 63, Finlay Drive Glasgow, E 1, M.B. Glasg (1943), and *Peter Augustine Smyth*, registered as of 33, Lillie Road, London S W 6, M.B N U I (1927)

In May 1950 the Council postponed judgment for one year after having found *Garden Hepburn Sicapp*, registered as of 8, Bath Street, Stonehaven, Kincardineshire M B Aberd. (1928), proved to have been convicted on charges of being in charge of a car while under the influence of drink. After hearing that the practitioner had been convicted of a similar offence earlier this year and that his appeal against this conviction was to be heard in the High Court of Justiciary in Edinburgh, the council decided to postpone judgment further until its session in November, 1951

Judgment on *Joseph Kevin Conlan* registered as of 81, Strubbington Avenue, North End, Portsmouth, M.B Durh (1940) was in May, 1949, postponed for two years the practitioner to appear at the session in May 1951 and produce testimonials Dr Conlan was not present but a letter from him and enclosed testimonials were read. The President announced that the council had decided to await the further appearance of the practitioner in November 1951 when he would be expected to produce full and up to-date testimonials as to his conduct

NEW CASES

The President announced that the council had directed the Registrar to erase from the Register the name of *Stanislaw Gerlecki* provisionally registered as of flat 2, 132, Cromwell Road, London, S W 7, MED DIP Warsaw (1936) The case was heard in camera.

Gurdit Singh Malik, registered as of 1, Hailey Road, New Delhi India, M.B Lond. (19 7) was charged with having given an international certificate of inoculation against yellow fever for Mrs. Edill Sydney Smith, of 10, Wenger's Flat, New Delhi, when he had not inoculated her, this certificate being untrue, misleading and improper within the meaning of paragraph 1 of the Warning Notice The case was postponed at the November session to enable the practitioner to arrange to be legally represented. Dr Malik did not appear and was not represented. The council decided to hear the case in his absence

Mr F P Winterbotham, solicitor to the council, presenting the facts, explained that India had taken considerable precautions against the entry of yellow fever, and the issue of a false certificate would defeat the purpose of the government There was no date on the certificate, but it stated that it was not valid "for more than 4 years from the date of the last inoculation 15-6-48 ' It gave the origin and batch number of the vaccine as 'Haffkine no 426" It had been found that no such tube of batch no 426 had been used for yellow fever, it would seem, therefore, that the practitioner had made a false statement

A letter from the practitioner to the Registrar of the General Medical Council, which Mr Winterbotham read, stated that Mrs. Smith came to him first in January 1948, for a cholera injection as there was a scare of cholera in New Delhi 'She came back again in June, 1948, for cholera injection which was due as she was going back to Europe She had her necessary injections which were entered in the book of certificates supplied to her by Air India, Ltd" She already had a certificate for yellow fever inoculation, given to her by an army medical officer in 1947 Dr Malik explained to her that she was protected for four years and did not need another injection until 1951 But she insisted on having a certificate written in the book, as it would be more convenient for her to have all the certificates together 'Knowing that she was protected against the infection, I complied with her request, which I would never have done otherwise" Dr Malik's letter stated that he gave an explanation of the facts to the director-general of health services, government of India, and at his request produced the original certificate issued to Mrs Smith by the army medical officer "Thereafter I was given to understand that my explanation was accepted and no action was to be taken against me" He ended "I sincerely apologise for the indiscretion committed by me and I hope you will kindly be pleased to overlook my lapse"

Mr Winterbotham said that the government of India took a serious view of the case because Dr Malik was extending the immunity for a period beyond that to which it ought to extend after the inoculation on March 31 1947 A letter from the director-general of health services, India, further explained that Dr Malik's name was not borne on any provincial Medical Register in India, and therefore the matter came before the council.

After consideration in camera, the President announced that the council had found the facts alleged proved to their satisfaction, and, that in relation to the facts so proved, the practitioner had been guilty of infamous conduct in a professional respect They directed the Registrar to erase from the Register the name of *Gurdit Singh Malik*

COMMITTEE APPOINTMENTS

At its sitting on May 22, the council elected the following to form the Medical Disciplinary Committee

Members for England and Wales—Dr W Russell Brain, Prof R J Brocklehurst, Dr J A. Brown*, Dr O C Carter* Sir Henry Cohen Dr H Guy Dain*, Prof R B Green, Dr E A Gregg*, Lord Nathan†, Sir Cecil Wakeley

Scotland—Dr R W Craig*, Miss Florence Horsbrugh, Dr J A. Kerr Sir Sydney Smith

Ireland—Dr James Boyd, Dr Frank Kane*, Mr R A Stoney

*Direct representative †Lay member

The council elected the following to the Penal Cases Committee

England—Dr J P Hedley, Mr J B Hynd, Mr N E Waterfield.

Scotland—Mr Andrew Allison.

Ireland—Prof J M. O Connor

Under regulations approved by the council, members of the Medical Disciplinary Committee will hold office for one year, and will be eligible for re election The committee elected at the May sitting will, in future, hear cases in November and in the following May, and at any intervening session The president is an ex officio member of the committee

BUSINESS OF COUNCIL

Dr HEDLEY, presenting the report of the Finance Committee, said that there was a deficit on the accounts for 1950 of £3293 One of the largest items of expenditure (£2840) had been the cost of exceptional repair work and alteration of premises which was not recoverable from the War Damage Commission The result of the increase in registration fees from £5 to 11 guineas, which came into operation on Oct. 11, 1950, was already obvious, and Dr Hedley said that in the next year or two, when the amount spent on the repairs and improvements had been wiped out, the council would be comfortably off financially

Dr DAIN chairman of the Pharmacopœia Committee, reported that 40 094 copies of the *British Pharmacopœia* 1948 and 3721 copies of the *Addendum* 1951, had now been sold. The report of the British Pharmacopœia Commission stated that building repairs to the laboratory were now complete It was expected that chemical checking may not be possible It is at this point that the present system fails

Because a prescription may be required in two places at the same time, it follows that there must be at least two identical documents—the original and a facsimile—one to be used by the pharmacist, the other to be kept on the ward as a check for the nurse and for the information of the prescriber The “ medicine chart ” should be discarded, together with the usual individual prescription sheets Instead, each ward should have an interleaved prescription pad, on which drugs may be prescribed for any patient in the ward The pages of the pad are perforated so that five prescriptions appear on each leaf, the under side of each alternate leaf is coated with carbon black and is adhesive at one edge Automatically each prescription will appear as a facsimile on the perforated under leaf

The upper, original prescription slip is sent to the pharmacist and retained by him until the patient is discharged Then all the prescription slips issued for this patient, pasted in chronological order on to standard size sheets of paper will be returned to the ward for filing with the patient's case history Thus the original prescriptions with details of all the drugs supplied to each patient will be preserved for record purposes The pharmacist will not be aware of the cancellation of a drug therefore, to complete the record, the date of the cancellation should be noted on the original prescription when it is eventually returned for filing

The facsimile prescription is kept on the ward Each patient will have a printed prescription mount to which each facsimile prescription is affixed by means of the adhesive edge, Mounts are arranged in patient order for the convenience of the prescriber, the prescription sheets on the mounts are arranged in time order for the convenience of the nurse Sections on the prescription mount correspond to the usual medicine rounds so that the nurse administering drugs can readily pick out the drugs required for each patient This arrangement avoids the need to make a copy “ medicine chart ” The nurse uses the prescription mount every time a dose of medicine is administered When the patient is discharged his prescription mount bearing the facsimile prescription slips may be destroyed

By means of the prescription mount the prescriber has on one sheet of paper complete up to date details of all the drugs being administered to each patient If a drug is to be stopped, or the drug or dosage is to be changed, the prescriber cancels and dates the appropriate facsimile prescription slip and writes a new prescription if required Thus any change in treatment will be immediately effective without verbal instruction or confirmation It follows also that no drug will be administered without a written authority, and that unauthorised prescribing will be prevented

My thanks are due to Miss M J Marriott, hon secretary of the Association of Hospital Matrons for permission to use the report of the annual general meeting of hospital matrons, 1950 I should also like to thank the many members of the nursing staffs of hospitals in the Oxford region for their frank discussion of the nursing problems and practice

Specimen copies of the prescription pads and prescription mounts may be obtained from Messrs. Maestrom Ltd , Holly Lane, Birmingham, 24

PROVINCIAL TEACHING HOSPITALS

Boards of Governors

THE Minister of Health has made the following appointments, mainly to fill vacancies caused by the retirement in rotation of one third of the members, to the boards of governors of the ten provincial teaching hospitals in England and Wales Of 102 appointments, 78 are reappointments of retiring members, 3 appointments are still outstanding The names of medical members are shown in bold type

UNITED NEWCASTLE UPON TYNE HOSPITALS

Reappointed Robert Muckle, now appointed chairman, Viscount Allendale, C.B , M C Lord Eustace Percy, P C , Viscountess Ridley, J.P , Sir Walter Thompson, J P William Allen , Alderman P S Hancock, J.P , O B E , Mrs. I Horn, M B E

New member Prof B W Abrahart

UNITED LEEDS HOSPITALS

Reappointed Sir George Martin, K B E , J.P , chairman, Prof **Digby Chamberlain,** F R C S M R Hollings B CH.D J C Hunter , W L Lawton, C B E , J P the Rev Canon A S Reeve , W S Hill , W W Powell , Richard Wheater Alderman Joseph Wilkinson, J P

UNITED SHEFFIELD HOSPITALS

Reappointed A Ballard, chairman , **J L. A. Grout,** M.C , F F.R , Lieut Colonel N Gervis Pearson, D S O , M.C , G F Young , J V Bibby, D S O , W R S Stephenson

New members Miss Anne Wetherall D J Haggie **J E Stacey,** F.R C O G Jack Ford , one appointment outstanding

UNITED CAMBRIDGE HOSPITALS

Reappointed Thomas Knox Shaw, M C , chairman , Mrs. H A Adrian Mrs E M Charvet , W M Francis , Alderman E T Halnan R H Parker, M C , Mrs Emily Parsons, **A. S H. Walford,** F R C S , T G P Spear

New member **Janet E Bottomley,** F R C S

UNITED OXFORD HOSPITALS

Reappointed Sir David Lindsay Keir, now appointed chairman , **E M Buzzard,** F R C.P , Prof **A. D Gardner,** F R C P Mrs G Hewitson , A W H Booth King , **J C Scott,** F R,C S , E A Smewin , **Janet Vaughan,** O.B.E, F.R C.P , Mrs M A Johnson.

New members **Gordon Scott,** M B the Rev John Lowe

UNITED BRISTOL HOSPITALS

Reappointed C C Clarke, chairman , Prof **R. J Brocklehurst,** D M , Prof **A V Neale,** F.R C.P G F Bullock, M.B.E , the Rev K L Parry

New members **J W E Snawdon,** M.B , M D.S. **W A. Jackman,** T D , F R C S E Miss G M Morgan W J Munslow , Philip Hopkins.

UNITED CARDIFF HOSPITALS

Reappointed G D Shepherd, M B E , J.P , chairman, Sir **David Rocyn-Jones,** C B E F R.C S E , J.P , Prof **G L Strachan,** F R C O G , Alderman the Rev W Degwel Thomas, Alderman Sydney Jones Alderman Mrs D M Rees, M P , Alderman R G Robinson, J.P , Ernest Tear, J.P , Sir Ivor Thomas

New members **J D Spillane,** F.R C.P one appointment outstanding Mr Lewis Lewis appointed for the period ending March 31, 1952, vice Sir Willie Reardon Smith (deceased)

UNITED BIRMINGHAM HOSPITALS

Reappointed S F Burman, M.B E , chairman , C L Chatwin **A. L d'Abreu,** O B E , F R C S Alderman W L Dingley V W Grosvenor W H Newton , E A Norton, W J Simpson , T A Hamilton Baynes

New members Councillor A Shanks, M.C **R. P Scott Mason,** M C , F.R.C.S

UNITED MANCHESTER HOSPITALS

Reappointed C M Skinner, chairman , Percy Chadwick, J.P , T M Larrad Sir **Harry Platt,** F.R.C S Prof **W H Semple** , Prof **W I. C Morris,** F.R.C O G , James Sillavan

New members **F R Ferguson,** F R C P , Mrs C M Spafford , W J Curley , one appointment outstanding

UNITED LIVERPOOL HOSPITALS

Reappointed T Keeling M A , J P , chairman A N Denaro, M.B E , J P Prof **W M. Frazer** O.B E , M.D , Prof **T N A. Jeffcoate,** F.R C O G **J T Morrison,** O B.E., F R C.S ; Prof E A. Owen

New members L H Buckley, J.P Mrs. J Bingham, J P , **B L. McFarland,** F R C S T J D Largo, C B E

Miss Winifred Armit housekeeper to one of the old ladies on whom Dr Murray called on Sept. 12, said she noticed nothing wrong with him. He was a conscientious man, he looked after the old lady very well indeed and was always completely sober Dr R G Miller told the committee that he had found Dr Murray an excellent assistant—conscientious, trustworthy, hard working, and very well liked by the patients When he had completed his sentence Dr Miller would be willing, if the committee s decision allowed it to take Dr Murray back as an assistant, and, if he wanted to take a partner as a partner

Mr Richards, in his address said that Dr Murray was no confirmed alcoholic He was a quiet, unostentatious man, who took great care of his patients This was an isolated incident, brought on by overwork All the evidence was that the collision occurred on Dr Murray s side of the road. He had been strongly advised to appeal against the conviction, but had refused

The committee decided that the Registrar should not be directed to erase Dr Murray s name from the Register

CHARGE OF PROCURING DRUGS

Henry William Miles Williams registered as of Pantacelyn, Merthyr Mawr Road Bridgend, Glam. M.R C.S (1923) appeared on a charge of having been convicted at Pontypridd Police Court on April 27, 1949 of six offences of unlawfully procuring drugs when he had been fined £15 for each offence, and costs of £10 10s and of being convicted at Porth Police Court, on Nov. 9 1950, of driving a car under the influence of drink or drugs, when he was fined £5 5s and £2 12s 6d costs and disqualified from holding a driving licence for 12 months and of driving a car in a dangerous manner for which he was fined £5 and had his driving licence endorsed. Mr C Morgan, instructed by Messrs. W R. Davies solicitors, on behalf of Dr Williams admitted the convictions which were proved.

Mr Winterbotham, dealing with the offences in 1949 said that during investigations in another matter the police noted that the name Edwards occurred frequently in the register of a chemist for morphine Edwards was a patient of Dr Williams and it was evident said the police that he was the " messenger for Dr Williams. There was no direct evidence that Dr Williams himself took the thirty ½ grain morphine sulphate tablets so obtained. After the conviction he signed an undertaking not to obtain dangerous drugs

With regard to the second conviction, a police constable found Dr Williams in his car his pupils were dilated, and his speech thick. The police officer took a box of tablets, which were found to contain ' Sodium amytal Sodium amytal had been prescribed for Dr Williams by a psychiatrist The chief constable pointed out that sodium amytal was not one of the drugs which Dr Williams had undertaken not to use.

Dr Williams in evidence, said that he served in the line from 1916 to 1918 until, at the age of 20 he was severely gassed with phosgene and mustard gas. After being in hospital for some time he was discharged from the Army He qualified in medicine He continued to suffer from the effects of the gassing He had a slight intention tremor which became pronounced sometimes and prevented him from taking up surgery as he wished. He decided on general practice and joined Dr Clarke in 1937 During the late war' the house in which he lived at Porth was destroyed by enemy action whilst he was inside This seriously affected his health. At some time in the 1940 s he started using morphine and obtained supplies through a patient he always paid for them. In 1948 he told Dr Clarke and as a result of the latter s advice went to a hospital as a voluntary patient Since he had come out of hospital he had not used a dangerous drug He had been advised to take sodium amytal during attacks of migraine he used no other drug On Oct 5 1950, he had a bad attack of migraine and took sodium amytal. Dr Williams explained the circumstances which led to his conviction for driving whilst under the influence of drink or drugs on this occasion he had pleaded not guilty Evidence had been given that a slight trace of sodium amytal was found in his urine and no evidence of alcohol.

In reply to the president Dr Williams said that he had been a partner of Dr Clarke s but after the first offence he had become an assistant He had taken morphine for about three years he took quite an amount—as much as 3 grains He was under treatment in hospital for six weeks. Asked by the president if he had severe withdrawal symptoms witness said he had not he had been under deep narcosis. He found the sodium amytal steadied him.

The vicar of Porth, the Rev J A. J Jones said the people had a regard and affection for Dr Williams

Dr Clarke said he was certain that since Dr Williams came out of hospital he had not taken morphine The psychiatrist had recommended witness to give Dr Williams sodium amytal Dr Williams had periodic attacks, and under sodium amytal got over them. In reply to the president, Dr Clarke said he had the impression that Dr Williams got periodic cravings for morphine but he was certain that he had taken none. He told Lord Nathan, a member of the committee, that there had been no complaints from patients about Dr Williams

Mr Morgan pointed out that Dr Williams had obtained morphine for his own use and there was no question of any fraud on the health service He had made heroic efforts and had conquered the habit.

The committee did not direct the Registrar to erase the practitioner s name from the Register

CHARGES OF DRUNKENNESS

John Vincent Gill registered as of 3, St John s Park, Rosetta Belfast M.B Q U Belf (1944), was charged with having been convicted at Belfast in 1948 and in 1950 of driving a car under the influence of drink. The convictions were admitted and found proved He was represented by Mr N Leigh Taylor

In evidence Dr Gill stated that on the first occasion he had arranged for another practitioner to look after his practice, while he went to a party He arranged for his wife to drive him home but she asked him to get the car out of the car-park it was while he was doing this that he was arrested. On the second occasion he was also arrested whilst parking the car, he was at that time worried that his wife might have another miscarriage These were isolated incidents. Since the last conviction he had joined a total abstinence association connected with the Roman Catholic Church.

The committee postponed judgment for one year until May 1952.

Harold Stanley Groves, registered as of the Poplars Blagreaves Lane Littleover Derby M.R.C.S (1915) was summoned to appear on a charge of having been convicted on Oct 10 1949 at the Magistrates Court Derwent Street Derby of driving a car under the influence of drugs, when he was fined £30 and 6 guineas special costs and his licence was endorsed, and of being fined £20 and 7 guineas costs and disqualified from holding a licence for 12 months at the same court on Jan. 3, 1951 for being under the influence of drink to such an extent as to be incapable of having proper control of a motor car

Dr Groves was not present Dr D A. Skinner of Taylor Simpson and Morley solicitors, said that although he had advised his client to come he had said he did not feel equal to appearing before the committee. After consideration in camera, the president announced that the committee had decided to proceed with the case in the absence of the practitioner

The offences were admitted and proved. Mr Winterbotham presented the facts. Mr Skinner said that on the first occasion the drug from the effects of which Dr Groves was suffering was chlorodyne which could be purchased by the public. The magistrates found a special reason why the statutory disqualification, following conviction of driving a car under the influence of drugs should not be imposed. Dr Groves at the time of the offence had been suffering from headache and diarrhœa. Dr Groves ceased practice in April, 1949 and was not engaged in a professional capacity at the time of the second offence He had an unhappy life with his second wife and it was she who informed the police, who watched him go to his car and as soon as he got in, arrested him. The magistrates imposed a lesser fine on this occasion than they did for the first offence

The committee postponed judgment for six months, the president saying they would wish to see Dr Groves in November

James William Hay registered as of 51 Spencer Street Carlisle M.B Aberd. (1924) was charged with convictions of driving a car whilst under the influence of drink, of driving a car without due care, and of being found drunk the offences occurred in 1938 1946 1950 and 1951 The convictions were proved and admitted.

Mr P Strong of Messrs Wright Brown, and Strong, solicitors, said that Dr Hay had been having treatment with Antabuse at Crichton Royal Infirmary and had undertaken not to touch any alcohol in future

The committee postponed judgment for one year, until May, 1952.

investigations would commence shortly on standards and tests for substances described in pharmacopœial monographs

Educational Business

The annual returns for examinations, presented to the council, showed that seven universities—Birmingham, Cambridge, Dublin, Manchester, Oxford, St Andrews, and Sheffield—and the Scottish and Irish Conjoint Boards held no examinations for diplomas in public health during 1950 Commenting on this, Dr R M F Picken said "This 'creeping paralysis' has been going on for years, the public health service has become less and less attractive" This trend had become more marked as a result of the National Health Service Act It was extremely difficult to get candidates to come forward for the D P H, because they felt that it was not worth their while to become medical officers of health. The answer could not be found in the council The President remarked that the main source of candidates was London University, along with the English Conjoint Board and the National University of Ireland Dr Picken pointed out that a large number of the students at the London School of Hygiene and Tropical Medicine were not intending to enter the public health service in this country

The council adopted draft regulations under section 2 (i), (ii), and (iii) and Section 3 (iii) of the Medical Act, 1950, as to the experience to be required after qualification before full registration in the Medical Register These draft regulations, which are subject to approval by order of the Privy Council, provide that the applicant shall have been engaged in employment as a house officer for 12 months—6 months in medicine and 6 months in surgery Not more than 6 months in midwifery or more than 6 months in a health centre may be reckoned towards the completion of this 12 month period These regulations will not come into force until the "appointed day" under the Act, and the president reminded members of what he had said in his addresss about the council not being precipitate in the matter

The council considered replies from licensing bodies to a circular concerning the compilation by the council of a list of hospitals, &c, approved by these bodies for the purpose of section 2 of the Medical Act The President reported that all bodies seemed to agree on reciprocal approval, as far as hospitals were concerned All agreed to keep the list up to date if it was maintained by the council. Some universities proposed to approve hospitals in the Dominions and the U S A (the U S A had many vacant posts), and Colonial authorities might insist on the Colonial student returning to the Colony to work after qualification The president agreed that hospitals in the U S.A or the Dominions or Colonies so approved by licensing bodies should not be included in the list The list would follow, with modifications, the arrangement of the *Hospitals Directory*

The council discussed at length whether posts, as well as hospitals, should be included Professor Green opened by explaining why the University of Durham felt it was not possible to give complete reciprocity of posts, as opposed to approval of hospitals In the discussion it was suggested that the body which licensed the student should inform him of the type of appointments that it would approve, and, to meet the danger that two 6 month periods in two specialties might be taken, it was stated that specialist posts could be suitably marked, with an explanation that two such posts would not be acceptable, while one unmarked and one marked post would be Prof A P Thomson read the note which the University of Birmingham was proposing to issue on the pass list, for guidance He also said that the director of studies would write to the student's chief within six weeks of his appointment, and if he received an unsatisfactory report would visit both chief and student (for things could be unsatisfactory because of the chief as well as because of the student), in this way any difficulties could be overcome early, instead of the student completing his 6 months and then finding himself with an unsatisfactory report The discussion concluded with Professor Green saying he saw no objection to a comprehensive list, so long as there was no suggestion that any combination of posts in that list would be accepted by any particular licensing body

The council discussed further educational business in camera

The session was concluded on May 23

Medical Disciplinary Committee

The Medical Disciplinary Committee met on May 24 and 25

This committee now exercises the disciplinary functions of the council, and it accepted the recommendation of the Penal Cases Committee that as from May 22, 1951, the Warning Notice should be issued, with such variations as the circumstances might require, by the Medical Disciplinary Committee, in lieu of the council.

The question of the application of paragraph 6 of the Warning Notice, which deals with advertising and canvassing, to sound broadcasting and to television is to be discussed by representatives of the British Medical Association and members of the Medical Disciplinary Committee and the Penal Cases Committee, acting jointly, since in the normal course both committees would be concerned with any reconsideration of the Warning Notice.

The annual report of the council of the B M.A for 1950–51 "noted with concern the laudatory references sometimes made to medical practitioners in announcements regarding forthcoming television programmes and also in actual performances" The council considered that "the increasing departure from anonymity and the references to appointments, experience, and achievements in the medical field are a possible source of danger to the individual concerned and contrary to the best traditions of the profession"

Correspondence read at the meeting of the committee said that the B M.A would submit a memorandum on the subject

RESTORATIONS TO REGISTER

The committee directed the Registrar to restore to the Register the names of *John Matthew Campbell*, *Bernard Drummond Hendy*, and *Vincent Blumhardt Nesfield* Under the new procedure these cases were considered in camera, and the result announced to the applicant when strangers had been readmitted

MANSLAUGHTER CHARGE

James Joseph Murray, registered as of Clooneyquin, Castlerea, co Roscommon, L.M R C.P and R C S Irel (1941) was charged with having been convicted of manslaughter at Chester Assizes on Oct 30, 1950 when he was sentenced to 3 years' imprisonment and disqualified from holding a driving licence for 10 years The conviction was admitted and proved Dr Murray was represented by Mr Norman Richards.

Mr Winterbotham, presenting the facts, said that in the evening of Sept 12, 1950, Dr Murray's car ran head on into a motorcyclist, who was killed, the accident happened on Dr Murray's right side of the road That morning Dr Murray had got up early, complaining of a headache He had some whisky and went back to bed, another doctor looked after the practice Dr Murray got up in the afternoon to see some elderly ladies about whom he was worried, and afterwards went to some public houses Evidence was given by doctors who examined him after the accident that he was, in their opinion, under the influence of drink, although he performed many of the tests satisfactorily Dr Murray in evidence had stated that he could not say what had happened at the accident

Miss Bessy Barret, a certified midwife, said that Dr Murray had been working very hard for two weeks previous to the accident he had given up his half days to do maternity cases. On Sept 12 she saw him in the morning and at mid day, when in her opinion he was sober There was never any suggestion of drink taking while she had been working with him professionally He was a most conscientious doctor

In England Now

Running Commentary by Peripatetic Correspondents

HE action of the Marylebone authorities in refurnish- the Baker Street apartments of Mr Sherlock Holmes et another example of civic patronage Mr Holmes rted the borough many years ago and has since ained in retirement in Sussex His one incursion the realms of scientific detection during recent s was his elucidation of the problem of the Lion's e Yet he is honoured by the district which he ned, while another Baker Street inhabitant, Mr on Blake, is completely ignored Without those antages enjoyed by Holmes, Mr Blake exposes evil- s twice a month He has no Dr Watson to give him ap diagnosis but relies on his own prodigious memory rovide medical information Take for example his se of The Hollywood Contract" in which a young ian was recently persuaded to impersonate a leading star But for the acumen of Mr Blake, this remark- fraud might be continuing still Blake, believing actress to have been murdered, paid a visit to her age where he found a mat with an ominous stain on If the stain proved to be human blood the case would closed Without hesitation, he commanded his stant, Tinker, to take the mat back to his laboratories re, as he explained, a quick Wassermann test would blish its identity So far as is known, he was nously unacquainted with the actress, so we can marvel at his brilliance in realising that such a would be specific In comparison, Sherlock Holmes ears a mere charlatan. Why then should Holmes ive the honour due to Baker Street's greater son?

often have to refer to tables and charts relating ace area to body-weight Only nurses and others have to wash patients all over have any idea of the e variation there is in people's surface area For ance, a frail woman of 5 ft 2 in. may have a surface of 14 sq ft, whereas your well-upholstered 6 ft n's surface will cover 22 sq ft or more In the mary way, even in our student days, we doctors ely try our hand at giving human beings a rub down, grooming a horse brings home to one what surface a really means I don't know how many square feet re are on a 14-hand or 15-hand horse, but to the ateur groom its area seems about the same as a tennis rt's. What must it be like to rub down an elephant? m told on reliable authority that it about reaches the it of human endurance and that a machine has refore been devised for doing the job easily and editiously

ouldn't we have a smaller model to mechanise bed- hs? "Only over the ward-sister's dead body," you l say But I am not so sure, there has been a big nge in the sister's outlook on manual labour in the t twenty years. The scarcity of nurses certainly has nething to do with it Even sister-tutors no longer k on hard labour as an essential part of a probationer's ining So I fancy everybody in the ward would wel- ne my Robot Bed-bather especially the patients, en they found that it couldn't have cold hands because adn't any hands at all.

* * *

see that doctors visiting London during the Festival advised to use public transport rather than a car ause of the difficulties confronting motorists in the tropolis. What with traffic-blocks, local variations the enforcement of parking rules and pedestrian ssing places and the certainty that there won't a vacant place to park the car within a mile of one's tination it isn't worth while using a private car short journeys in London—unless of course one has hauffeur and or a shiny new Jaguar of vast publicity ue

One solution is to ride a bicycle As students we all l them and became expert at riding them through ffic in any weather I learnt a lot of tips from a ckney errand-boy in the next bed when I was warded h an appendix His main advice was 'Wherever *yer gets, Guv, stick onter yer bike like bleedin'* glue and yer won't get nipped—see?" "Nip" was a favourite word of his with a wide range of meanings It covered such eventualities as being fatally crushed between two buses or (and this seemed to him worse than death) being taken up by the police for the minor offences he committed from time to time

My early training came in useful last week when I had to get my son's bicycle from Liverpool Street Station to Charing Cross. With the foolish pride of middle age I was tempted to take a taxi, but it was a fine day so I decided to chance a ride Believe it *or not*—and it was in the evening rush-hour—I did the journey in 12 minutes dead, without chasing the amber or any other of the motorist's time-saving tricks And I did *not* get nipped

I shall not be surprised to see our doctor sons returning to the habits of our doctor fathers, unencumbered by their coat tails and the need for keeping up appearances And those who must have publicity will no doubt appear on the latest Rolls Corgi motor scooter

* * *

Whatever you do, don't follow my example and arrive in Canada on July 1 Having spent 2 days "doing New York," you will arrive, footsore but blithe, in the great university city at 9 A.M. So high are your spirits that you will merely laugh at battered suitcases, once proudly locked, now, after one short night on the C.N.R., battered string-bound wrecks. You will mother them towards a taxi and sink back, thinking smugly how impressed your chief will be at your prompt appearance on a Saturday

Settled in your room, two of your only three dollars gone to the taxi-driver, you will walk briskly to the hospital, looking we trust the epitome of that rather tiresome soul, the Competent Woman Doctor The long hot empty streets will puzzle you, the shuttered silent shops perplex you, and the ominous words on the bank 'Closed for Dominion Day, July 1" petrify you. Reaching the hospital you will hear, "Oh, no, I'm afraid he's not here—he's at his log cabin. No, I'm afraid he isn't either, he's on vacation. No, she's gone to Niagara for the weekend," and then, more coldly, 'I'm sorry, we can't cash any traveller's cheques till Monday, you see, it's Dominion Day" You will totter away, clutching your one remaining dollar, to spend a solitary and hungry week-end Your useless cheques make but eloquent testimony *to the joyful* news *Canada is a Dominion.*

No, not on July 1

* * *

Professors of medicine are fond of emphasising the importance of taking an accurate and complete history They tell us that it is of greater value than the physical examination. Indeed so impressed are they with its advantage that they sometimes prefer to interrogate the patient concealed behind a screen. To this admonition and exhortation we lesser mortals react—perhaps with respect and admiration perhaps with less respectful tolerance of senile idiosyncrasy, perhaps with impatience at pomposity and a longing to see the experts trying to practise their leisuredly methods in our crowded surgeries or outpatient departments. And yet

A well-covered matron appeared with an introduction from Dr X She had lost 2 stone in the past two months and he would be glad of investigations to ascertain the cause We undertook the weary time-consuming procedure of proving negatives, at the end of which we asked the patient if she could think of anything that might be responsible. 'Well," she replied "I went to Dr X two months ago because I was over-weight, and he put me on a diet

* * *

A few years ago I was out walking one evening when I lost the path in a wood After a few minutes' meandering, I saw two cigarettes burning through the trees, and after a moment's hesitation called out "Excuse me, but is there a path near here?" No answer A further call also produced no response, and beginning to feel annoyed I walked over—to find two glow-worms Next day I checked up with Ishihara, and that was how I found I had a beautiful red-green blindness believe to be of limited value Primarily the interest of the G P is the whole person integrated in the social background, and not in any part of that person In any case, no labour is saved by such a breakdown, and most of the routine work of the G P does not lend itself readily to a breakdown on the lines of the division of clinical material which is possible in a hospital

Two exceptions to this are found in the work of the general practitioner obstetrician and the general practitioner physician

That midwifery properly comes within the province of the family doctor we have no doubt, but we are certain, too, that it can remain there only if the other responsibilities of the G P are small enough to enable him to devote a large part of his time to maternal care We find that to deal with 120 cases per annum within the group, the G.P obstetrician's list of patients under the General Medical Service must not exceed 1200, and that he must give four afternoons per week to maternity clinics Ideally these would be carried out at a centre which had adequate accommodation for the teaching of exercises and relaxation, for films, talks, discussions, and a mother's club All normal deliveries are carried out by the midwives, and the G.P obstetrician, working in the closest cooperation with them, must be available for advice and for emergencies such as suturing the perineum, postpartum resuscitation, and difficulties in labour

It is our view that the only major operative procedure that should be carried out in domiciliary practice is the application of forceps when the head is on the perineum, with another doctor present as anæsthetist All other operative procedures belong to the hospital obstetrician

The G.P physician must be a family doctor who, by training and experience, is of consultant physician status His function is discussed below

Any member of the group who, because of special experience, wishes to run a particular clinic—e g, in dermatology—is of course encouraged But each member is primarily a general practitioner with his own list of patients for whom he takes full and continuous responsibility A patient normally has access to other group members only through his own doctor, except that a duty rota is in operation and he may have to call upon the doctor on duty when his own is off duty

THE DISPOSAL OF ORGANIC ILLNESS

The G P can dispose of major organic illness in three ways he can treat the patient in the home with the help of the district nurse, the home help service, and the domiciliary consultant service, he can refer the patient to a general hospital, or he can admit the patient to a G P hospital In a G.P hospital the practitioner can assume complete responsibility for the case, or, if he is working within a group, he can attend to the patient under the surveillance of the G P physician, or he can hand over to the G.P physician entire responsibility for the patient while he is in hospital

Cases admitted to a G P hospital should be freely accessible to all members of a group practice, and the problems they present should be fully discussed at the routine meetings of the group The main responsibility of the G.P physician is to familiarise himself with the work done by his colleagues to ensure that their standards of diagnosis and treatment do not fall below those of general hospitals To be able to do this, it is essential that the G P physician has access to a general hospital, and he should hold a post of clinical assistant there

This arrangement successfully ends the problem of the isolation of the G P from his colleagues in hospital, and eliminates what has been a regrettable feature of the work of cottage hospitals in the past—namely, that in some cases the standard of treatment has fallen below that of general hospitals This is particularly the case in major operative surgery We can see no place for the G P surgeon, and, apart from minor surgery, we refer all surgical cases to a general hospital

On the other hand, we have found that with a group practice including a G P physician and a cottage hospital, the G P is fully able to treat the majority of medical cases that he meets in his practice without having to request admission to a general hospital, or make use of the domiciliary consultant service This continuous care by the G P of patients who have serious organic illness, enormously increases the interest of his work and encourages him to maintain and improve his standards of practice

FUTURE DEVELOPMENT

Rationalising the work of the practitioner can enhance his ability to deal with many conditions which are customarily referred elsewhere, and it can also have the purpose of giving him time to conduct research into the problems that confront his practice He should not compete with his colleagues in hospital and laboratory in the investigation of the obscure and technical, but he is in a unique situation to study the relation between disease and social factors, and can make a contribution in the understanding of the problems of childhood and psychoneurosis Solutions evolved in general practice will always have a wider field of applicability than those dependent on some special institution or apparatus

A group of G P s such as we have described is better placed for undertaking such work than is the G P working in isolation

CONCLUSION

The maintenance of high standards in medicine, particularly in general practice, depends primarily on personnel and not on buildings and equipment The development of the health services during the past forty years has seen the springing up of many services ancillary to that of the family doctor and mostly intended to compensate for the deficiencies of general practice The result has been that the practitioner has lost a large part of his responsibilities and the family doctor is now far from being the pivot of the preventive and curative services An end will be put to the curtailment of the functions of the G P only when his standards can be raised We suggest that in present circumstances this can best be achieved by developing group practice and encouraging the hospital registrar to enter this field—a field which will give ample scope for the application of the skill which he has obtained in his long training and which will enable him to continue to do work which is professionally satisfying

The introduction of the National Health Service has seen great improvement in the hospital services but there has been no parallel improvement in the general practitioner service The most urgent need at the moment is for a body, equivalent to the regional hospital board which will take upon itself the responsibility for the planned development and improvement of general practice

---

‘ From its very nature virus research, like bacteriology in general, has tended in the past to concentrate on medical and veterinary problems It will probably always be carried on against a background of its significance for medicine But if one looks around the medical scene in North America or Australia, the most important current change he sees is the rapidly diminishing importance of infectious disease The fever hospitals are vanishing or being turned to other uses With full use of the knowledge we already possess, the effective control of every important infectious disease, with the one outstanding exception of poliomyelitis, is possible

“ Today the most intellectually exciting aspects of virology are not directly concerned with medicine As I see it, the main interest of the virus to biology now is the possibility of using it as a probe in the study of the structure and functioning of the cell it infects ’—*Prof* F M BURNET, F R.S, *Scientific American*, May 1951, p 51 pronouncements, whether of confirmation or refutation, after early and thorough investigation of a claim, would prevent much wasteful expenditure of time, money, and materials

DRUGS IN AMŒBIASIS

SIR,—In your leading article last week, I notice two separate quotations implying that "cyst passers" or "carriers" of *Entamœba histolytica* are now usually looked on as chronic cases of amœbiasis, and it is not quite clear whether or not you agree with this conclusion

Surveys of sections of the population of this country which have been made at different times show a carrier-rate ranging from 1 6 to 3 4%, and it is probable that these figures would be higher if repeated tests were done This means that at a conservative estimate between 1 million and 2 million of the inhabitants of Great Britain harbour *E histolytica* in their bowel. Is it seriously suggested that we have this enormous number of cases of chronic amœbic dysentery in our midst?

OFFICE MANNERS

SIR,—I should like to congratulate Brigadier Hardy Roberts on his article of May 19 It is full of that clear common sense which is the hallmark of the good administrator I hope that he will one day write a second article on the methods of dealing with the difficult case—for example, the member of the board or medical staff who cannot see any other point of view than his own

As a former "man at the Ministry" who has sampled Brigadier Hardy Roberts's persuasive hospitality, I can foresee that if this custom spreads some future Minister of Health may have to consider the reintroduction of the ancient Local Government Board rule for general inspectors It was to the effect that officers of the Ministry must never accept hospitality when visiting institutions in their official capacity!

LONDON SCHOOL OF HYGIENE ASSOCIATION

SIR,—A School Association has been formed, membership of which is open to all students who have followed a complete recognised course of instruction in the school There is a nominal entrance fee of 2*s* 6*d*, but no annual subscription Members are entitled to receive every year a copy of the annual report and any notices connected with the association It is hoped to arrange an annual "open day" and possibly an annual dinner A special association tie has been designed, which is obtainable at a cost of 17*s* 6*d*

I hope that all past students will join the association and maintain as close contact as they can with the school and staff Applications, together with the entrance fee of 2*s* 6*d*, should be sent to Miss K M Shaw, personal assistant to the dean

METHÆMOGLOBINÆMIA

SIR,—In your annotation of May 12, you say that "the newer sulphonamides do not cause methæmoglobinæmia" This prompts us to record some observations from the Premature Baby Unit at Hammersmith Hospital.

In the last few months we have seen five examples of methæmoglobinæmia in premature infants to whom sulphamezathine had been administered This type of cyanosis may sometimes be wrongly attributed to some other more serious complication, especially as it seems particularly prone to occur in the premature infant The blueness usually disappears within 48 hours or so of stopping [illegible] Two typical case histories are as follow

CASE 1—Birth weight 3 lb 10 oz Aged 16 days developed purulent blister on scalp Sulphamezathine 0 25 g first dose, and thereafter 0 125 g 6 hourly Diffuse cyanosis noted on 4th day of treatment, methæmoglobin 12% in venous blood sample, as determined by a Klett spectrocomparator Cyanosis disappeared within 48 hours of discontinuing the drug

CASE 2—Birth weight 3 lb 12½ oz Pustular eruption appeared on the neck on the 3rd day of life Sulphamezathine 0 125 g 6 hourly Generalised slaty cyanosis noted on 3rd day of treatment Venous blood sample showed 11% methæmoglobin Treatment continued for 7 days, 3 days later all cyanosis had disappeared

Medicine and the Law

Finding of Negligence against Doctor and Hospital

IN Wood *v* Thurston and the Governors of Charing Cross Hospital (reported in the *Times* of May 25) Mr Justice Pritchard awarded damages for negligence against Dr Thurston and against the hospital as his employers, assessing them at £350 under the Law Reform (Miscellaneous Provisions) Act, 1934, and £3200 under the Fatal Accidents Acts

The facts were unusual Mr John Wood, manager of the accounts department of a bank, visited two public houses with friends between 7 P M and 9 P M in August, 1948 Subsequently the party, walking westwards along the Strand, found a stationary lorry in their way as they came to cross Bedford Street Instead of walking round behind the lorry, Mr Wood elected to crawl on all fours under it As he did so, the lorry began to move, one of its rear wheels pinned him to the ground, but he was freed before the wheel went completely over him After lying down on the pavement for a while, Mr Wood went with his friends to the casualty department of Charing Cross Hospital He arrived, according to the learned judge's finding, intoxicated but not drunk, he insisted that there was nothing wrong with him and he explained what had happened with the lorry, Dr Thurston examined him, treated him, as the records showed, for nose bleeding, and found no evidence of bone injury (which the judge held meant no bone injury to the nose) The patient was then allowed to travel home, a distance of 11 miles, in a taxi cab Early next morning he was admitted to the West Middlesex Hospital, where he died at 7 A M Necropsy disclosed a fractured collar bone, fractured ribs (9 on each side), and severely congested lungs Death was attributed to shock consequent on these injuries. The widow's allegations of negligence consisted in the doctor's failure to diagnose the injuries and in the fact that the patient was allowed to make the taxi cab journey when not in a fit state to travel Dr Thurston, who denied liability, admitted the failure of diagnosis but pointed out that Mr Wood, being intoxicated, could give no accurate account of his accident and that the patient's reactions to pain were dulled by alcohol Mr Wood, he said, repeatedly stated that there was nothing the matter with him and that he wanted to go home In examining the patient he had (amongst other things) pressed his chest from side to side and from front to back and had examined the skull for signs of injury Mr Wood had shown no signs of shock or pain, there was no crepitus, sweating, pallor, or abnormality

Mr Justice Pritchard said he thought the examination had been less careful than the circumstances required It had been contended that the intoxication would deceive a doctor, he thought the story of the man having been under a moving lorry and having been touched by the wheel made greater care necessary in the examination The use of a stethoscope would almost certainly have revealed the patient's true condition As regards the taxi cab journey, whether the cause of death was shock

Ireland Mental Health Act of 1948 has already introduced radical reforms, and that in this country active preparation of a new Mental Deficiency Act has been in progress for some time.

In view of this, we feel that the pamphlet has served no useful purpose but has caused unnecessary distress to relatives of patients in mental deficiency hospitals.

DIURETIC EFFECT OF VITAMIN B_{12}

SIR,—Barnard and Weitzner[1] reported that single injections of 45–75 µg of vitamin B_{12} caused unequivocal increase in urinary output in 12 of 16 patients with normal blood pictures. They speculated on the mechanism of this action and suggested further clinical trials. Such a claim warrants further investigation, for œdema is too common, and too often unresponsive to treatment, for the present remedies to be viewed with complacency.

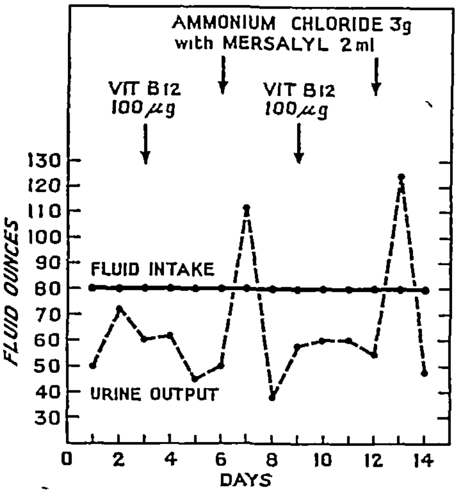

Fig 1

I have investigated this claim in 37 patients with normal blood pictures, comprising the following five groups:

1. 2 normal adults (1 woman, aged 32, and 1 man, aged 35).
2. 2 women, aged 54 and 58, with chronic nephritis. Both had generalised œdema with hypertension and nitrogen retention, the blood urea values being above 120 mg per 100 ml.
3. 1 man, aged 58, with the nephrotic syndrome due to Ellis's type II nephritis. His blood pressure and blood urea level were normal at the time of the test, but his plasma-protein level was very low at 4 g per 100 ml, and there was extreme generalised œdema.
4. 30 patients in congestive heart-failure with generalised œdema (14 men and 16 women, all over 48 years of age). In many cases the ætiology was mixed, but the main factor was considered to be arteriosclerotic coronary disease in 20 cases (3 with rheumatic mitral stenosis and 3 with calcareous aortic stenosis), essential hypertension in 5, cor pulmonale in 3, thyrotoxicosis in 1, and syphilitic aortic incompetence in 1.
5. 2 men, aged 52 and 60, with generalised œdema due to cirrhosis of the liver.

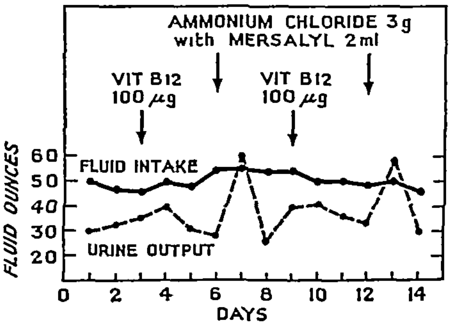

Fig 2

The simple low sodium diet described by Bedford[2] was carefully maintained for the 14 day trial period. This diet provides not more than 650 mg of sodium per day and allows a free intake of fluid. The fluid intake and the urinary output, from 6 A.M. one day to 6 A.M. the next, were measured and recorded daily. Fluid lost via the bowel, skin, and lungs was not taken into account, but no patient had vomiting or diarrhœa during the trials. Daily weighing was impracticable owing to shortage of staff.

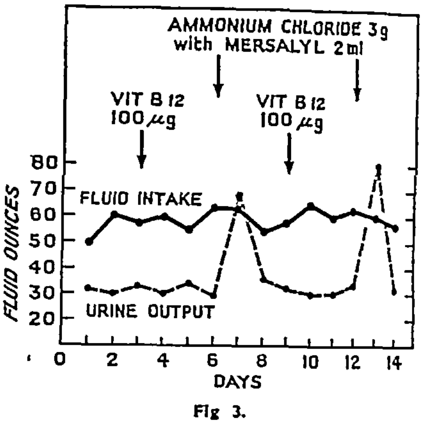

Fig 3.

The vitamin B_{12} was tested against a mercurial diuretic, as follows:

After 3 days on the low sodium diet, 5 ml of 'Cytamen' (Glaxo), equivalent to 100 µg of vitamin B_{12}, was injected intramuscularly at 6 A.M. 3 days later 3 g of ammonium chloride was given by mouth at night followed at 6 A.M. the next morning by 2 ml of mersalylum B.P. intramuscularly. After another 3 days the whole experiment was repeated.

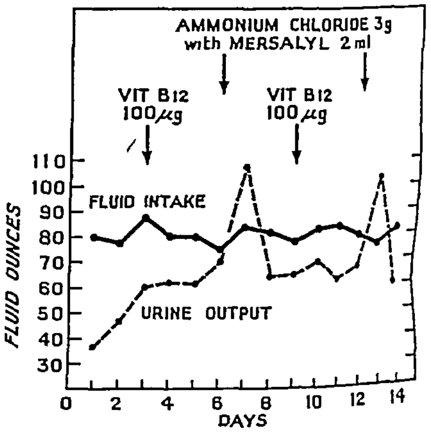

Fig 4

Figs 1–5 show the responses of the five groups of subjects. In no case was a significant increase (arbitrarily defined as output exceeding intake) observed following the administration of vitamin B_{12}, whereas in all cases the mercurial compound produced a diuresis, although this was occasionally within the normal range for the patient.

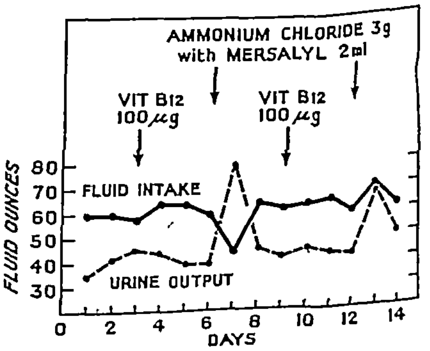

Fig 5

I conclude therefore that vitamin B_{12} has no significant diuretic effect on subjects with normal blood pictures, and thus has no place in the management of generalised œdema. (The diuretic effect of vitamin B_{12} on patients with blood disease is not considered here.)

The establishment of a Therapeutic Trials Committee in this country is long overdue, for authoritative

2. Bedford, P D *Ibid* 1950 ii, 823

play an important part in the affairs of the university and the British community in Cairo He devoted his leisure to acquiring an extensive knowledge of the antiquities of Egypt, a superb collection of photographs illustrative of this subject, and a number of private pieces of rarity and value In this strenuous and fruitful hobby he was assisted by his wife Viola, youngest daughter of Osbert Salvin, F.R.S, who was an artist of no small ability They had married in 1913 She predeceased him in 1947, leaving a son who is a doctor

Returning to Britain in 1933, after receiving the Order of the Nile and being admitted a member of the Royal College of Physicians in 1932, he was appointed as independent lecturer, and subsequently professor of *pharmacology at Cardiff There he expanded the depart*ment, playing an ever-increasing part in the affairs of the school of medicine, of the college in relation to the school of pharmacy, and of the university as a whole He continued the series of painstaking researches which led to a number of valuable contributions to his specialty, and wrote the articles on chemotherapy for the *Medical Annual* from 1937 to 1946 He was elected fellow of the Royal College of Physicians in 1937

In 1948 he married Amy, youngest daughter of the late R G Howson, of Stoke-on-Trent, who survives him.

J D P G writes "A man of taste, wit, and learning, widely read in classical and English literature, familiar with the byeways of France which he visited annually, discriminating in his praise or censure of a book, a wine, or a picture, skilled in working with metals or with woods, amiable, generous, and loyal, Heathcote was a lovable character His knowledge of his specialty was profound, and he laboured to achieve a synthesis between the pharmacist, the pharmacologist, and the clinician. As a teacher he was approachable, considerate, and helpful, never obscure or pedestrian He inspired a remarkable warmth of feeling in a whole generation of Welsh students and in his colleagues.'

JAMES ROBERTSON CAMPBELL GREENLEES

D.S O, M.A., M.B Camb

As we briefly announced last week, Dr J R C Greenlees, formerly headmaster of Loretto School, and latterly chairman of the South Eastern Regional Hospital Board for Scotland, died in Edinburgh on May 16, at the age of 72

Born at Glasgow on Dec 14, 1878, he was educated at Loretto, where he distinguished himself as a rugby player After qualifying he returned in 1908 to Glasgow, where he took appointments at the Western Infirmary and the Royal Hospital for Sick Children On the outbreak of war in 1914, he immediately volunteered, and for his services he was appointed D S O and created a chevalier of the Legion of Honour

He went to Loretto as headmaster in 1926 without previous experience of teaching, but under his leadership the school's reputation for scholarship and excellence in games was enhanced Because of the late war he deferred his retirement until 1945 He became chairman of the South Eastern Regional Hospital Board in 1947, and in 1948 he was appointed surgeon to the Royal Company of Archers

H A R writes "To make a name in the two professions of medicine and teaching, to have a distinguished record in the first world war, to have played rugby for Scotland seven times after a delicate childhood, is an unusual combination of achievements these are the highlights of Dr Greenlees s career It has been said that during his headmastership of Loretto emphasis was placed on the development of character, and it is in his qualities of sincerity, disinterestedness, and simple faith that the explanation may be found

"I cannot speak for his place in medicine as a general practitioner and children s physician in Glasgow Nothing much could be learned from Dr Greenlees himself, as most of his reminiscences consisted of humorous stories against himself Certainly, however, this period gave him a sympathy with the young general practitioner struggling to make a career in his chosen field. It may be said that Dr Greenlees was fortunate in his background and upbringing Be that as it may, he typified the outlook of 'noblesse oblige,' and regarded his advantages in life as a means which enabled him in fuller measure to serve the community He never ceased to be a physician even when a headmaster On his return more directly to the field of medicine as chairman of the Royal Hospital for Sick Children. Edinburgh his influence did much to weld this hospital—governing body, medical staff, and others—into one team His delight in this work was the close association it gave him with children—an association he regretted losing when he undertook work in a wider field as chairman of the South Eastern Regional Hospital Board, Scotland.

'Dr Greenlees threw himself, heart and soul, into the creation of the new hospital service—work he once described as 'more than an experience, an adventure.' He had definite views on most matters and was perhaps a little impatient with the intricacies of committee systems and the like His great strength was his obvious sincerity and disinterestedness and his great charm was that he granted such qualities to those who opposed him, and always insisted that they should be fairly heard

"He was keenly interested in the development of medicine He typified the high ideals of the true physician, and it is perhaps for his insistence that such ideals should be maintained in the turmoil of this revolutionary period in medicine that he will always be remembered In a new organisation, such as the hospital service it is easy for the machine to take hold of the individual The greatest contribution by men like Dr Greenlees to any organisation is that they give it a soul."

In 1922 Dr Greenlees married Allison Hope, daughter of Sir John Cargill, and they had a son and a daughter

or the leakage of air into the pleural cavity on account of the fracture of the ribs, the judge thought death would probably not have occurred if the patient had been kept immobile at once He added some consolatory remarks for the benefit of the defendant doctor There were very few professional men who had not made mistakes in the early stages of their careers

Public Health

Retrospect and Prospect in Poliomyelitis

THE World Health Organisation has made a brave attempt to survey the world trends of poliomyelitis in 1950 [1] This suffers considerably from lack of population figures to convert crude incidence to case-rates, and a little from differences in code of all countries only England and Wales group encephalitis and myelitis together That there should be no information at all from the U S S R or China is not surprising, but one wonders what prevents the inclusion of reports from Abyssinia, Bolivia, British Honduras, Egypt, Eritrea, India, Somaliland, or the Sudan

For most countries the case-incidence and deaths in 1949 and 1950 are compared with the medians for the period 1942–48 From these figures the countries can be divided into four groups

1 Incidence much higher than median in both 1949 and 1950, Australia, Belgian Congo, England and Wales, France, Mexico, U S.A.

2 Incidence much above median in 1949 and much below in 1950 Canada Iceland, Mauritius

3 Incidence much above median in 1950 only Denmark, Northern Ireland, Norway, Scotland, Spain.

4 Incidence about median in both 1949 and 1950 Belgium, Federal German Republic, Finland, Ireland, Italy, Sweden, Switzerland.

For some countries the yearly incidence since 1938 is also given, and a broader view of present trends is thus possible If the total incidence during the last six years is divided by the total for the six preceding years the following ratios are obtained Netherlands 0 36, Switzerland 0 66, Italy 0 89, Denmark 1 03, Norway 1 2, Sweden 1 3, Finland 1 41, Ireland 1 43, France 2 03, Canada 2 28, U S A 2 5, Austria 3 15, Scotland 5 2, England and Wales 5 7, Belgian Congo 6 1, Australia 10 3, Union of South Africa 13 5, Iceland 113, Mauritius 850 The remarkably wide range is probably a measure of the present lack of equilibrium between virus and man The virus almost certainly has no natural host other than man, climate is no bar to its activity, and thus wherever man lives the virus may live too As long, therefore, as poliomyelitis remains unpreventable it will continue to be a world problem, and statistical observations of this kind will continue to have great interest

Employment of Pneumoconiotic Miners

Men suspended under the Workmen's Compensation Acts because of pneumoconiosis or silicosis, unaccompanied by tuberculosis, may now take up employment in the coal-mining industry if they are passed by a pneumoconiosis medical board as fit to do so The scheme, which is voluntary, does not apply to men suspended for tuberculosis, pneumoconiosis accompanied by tuberculosis, or silicosis accompanied by tuberculosis

By Regulations [2] which come into operation on June 4, men passed as fit who take up work underground, or in a surface job involving the working or handling of any minerals taken out of the mine, will be able to claim a modified disablement pension under the Industrial Injuries Scheme if their condition gets worse They will be examined by a pneumoconiosis medical board before entering employment and will in any case be called up for further examination from time to time The amount of any disablement pension will be based on the difference between the assessment of disablement given at the first examination and any increased assessment given at a later examination after taking up work The men may also be able to qualify for special hardship allowance, unemployability supplement, constant attendance allowances, and hospital treatment allowance

Applications by suspended men to take up work in the coal-mining industry should be made on the form attached to leaflet N I 61, which gives further information and can be obtained at local National Insurance offices.

Public-health Salaries

Committee C of the Medical Whitley Council recommend to local authorities the following arrangements in applying the new (award) salary scales [1] to doctors who started duty in a first or new appointment on or after Oct 1, 1950

1 Doctors who started duty after Sept 30 1950, but before the date of the first award of the Industrial Court (Dec 8, 1950) should have the new salary scales applied to them in the same way as to doctors in post on Sept 30, 1950 —i e, as laid down in section III of appendix B to M.D C circular no 2

2 Doctors who started duty on or after Dec 8, 1950, but before April 1, 1951, should be dealt with as follows (*a*) for the period from the date of taking up duty to March 31, 1951, they should receive the salary at which they were appointed, (*b*) from April 1, 1951, onwards they should receive in full the new salary payable under the award, (*c*) increments should be paid as laid down in clause iii of section III of appendix B to M D C circular no 2

3 Doctors starting duty on or after April 1, 1951, should be paid the new (award) salary in full from the date of taking up duty

4 Where arrangements more favourable to the officer than (1) and (2) above have already been adopted by the authority those arrangements should remain in force

Statistics for Eire in 1950

In Eire the birth-rate during 1950, according to the registrar general,[2] was 21 0 per 1000 population—0 4 below the rate for 1949 The death-rate—12 0 per 1000 population—was 0 1 below the rate for 1949 The death-rate for all forms of tuberculosis was 0 8 per 1000 population (respiratory 0 6, other forms 0 2) compared with 0 9 (0 7, 0 2) in the previous year Deaths from puerperal causes amounted to 1 1 per 1000 births registered, compared with 1 6 for 1949 Infant mortality, which in 1949 was 51 per 1000 births registered, fell in 1950 to 45—the lowest ever recorded

Obituary

REGINALD ST ALBAN HEATHCOTE

M.A, D.M, B.Sc. Oxfd, F R.C.P

Prof R St A Heathcote, first incumbent of the chair of pharmacology in the Welsh National School of Medicine, Cardiff, died in London on May 19, in his 63rd year

Born in 1888, he was the youngest son of the Rev G Vyvyan Heathcote, of West Deeping, Lincolnshire He gave early evidence of his extraordinary powers of memory and academic brilliance and was admitted as a scholar of Winchester this early promise was not belied, he passed to New College, Oxford, again as a scholar, and in 1911 to University College Hospital as the first holder of the Theodore Williams scholarship He qualified in 1913, spent some years in the R.A M C during the war of 1914–18, and completed his service as a Surgeon Lieutenant-Commander R N V R After the war he returned to Oxford and was enabled to pursue those studies which had early appealed to him, joining the staff of the department of pharmacology and graduating D M in 1919 and B SC in 1922

It was in this year that Heathcote was appointed professor of pharmacology in the University of Cairo, proceeding to Egypt at the age of 34 to develop and expand his department, to train and encourage local students who might ultimately take his place, and to considered to have been substantially delayed by infection in 1 or 2% of cases There were no acute major post operative infections Investigation of the infected cases generally showed that every aspect of the treatment—toilet, excision, suture, and dressing—had been bad, and that the dresser was already known for indifferent work

---

[2] Quarterly Return of the Marriages Births, and Deaths registered during the December Quarter 1950 and Yearly Summary 1950 Government Publications Sale Office 3/4 College Street Dublin Pp 78 *6d*

For traumatic amputations the most commonly used method of closure was by a thin split skin graft, but composite ear grafts, palmar and thenar flaps, resuture of the amputated part, and proximal amputation were also done The 55 cases treated by simple split skin graft healed in an average of 24 1 days (range 10–40 days), in the more complicated types of repair (by flap or composite graft) the average time of healing for traumatic amputations was 30–40 days A personal follow up of 60 of these traumatic amputations showed that all were back at their old work except one, a boy aged 14, whose mother refused to let him run the risk of another similar accident Only 2 scars were tender to pressure, 5 showed some adherence of the stump to the underlying bed, and in more than 20 the stump was noticeable either because of loss of length and contour or because of the yellow colour of the graft

CONCLUSION

These results and healing rates (10–20 days for finger lacerations, and 10–40 days for traumatic amputations of the finger tip) can be improved, but they can be held to justify the continuance of this work by dressers under the conditions of accommodation, equipment, time, and teaching described

It would be impossible to assess accurately the value of work in this theatre in the training of dressers During their clinical period the dressers at Guy's Hospital have two appointments, each for three months, in which they do turns of duty in the surgery But the best work in the accident theatre is not always done by the senior dressers, what matters is the aptitude and keenness of each dresser In any group of dressers about a quarter have technical ability and are keen to increase their operative experience, they make the most of the opportunity the accident theatre provides About an equal number are the reverse, they have no liking for the operative side of surgery and will often persuade friends on duty with them at the time to undertake their operations The remaining 50%, however, seem to welcome the opportunity of sitting down quietly in a well serviced room and getting ahead with a detailed and comprehensible technical job Every doctor ought to be able to treat these common minor open injuries by modern techniques, it is in such an outpatient accident theatre that the dresser gets his best training in this work, but I feel that if he wishes he can obtain further important training there He can become familiar with the use of the light instruments which have been designed for handling and repair of delicate tissues, and which will be useful in many of his general surgical operations I like to think that in this theatre the dresser can also learn an attitude of mind to soft tissue injuries which may be called that of a “ biological dressmaker,” in that he can learn to regard every wound as an individual tailoring job needing a planned repair, and not the application of a standard treatment

There are other reasons to justify the reorganisation and the initial expense in providing such services. In every aspect of its work a teaching hospital should provide standards which the students take with them when they leave Casualty departments have for too long been the “ black holes ” of their respective hospitals They have been departments where, on the grounds of the numbers of patients to be treated and the apparent rarity of serious complications, work has been done which contradicts every maxim of good surgery both in practice and in principle, violating not only the rules for the control of infection but also every other concept on which good surgery depends These departments have also often been a prodigious source of unsupervised waste of material and of medical time to the hospital, and in man hours and disability to the State The general provision of facilities such as those described above, in addition to its beneficial effect on teaching, could also prove both a local and a national economy

We have a special debt to acknowledge to the department of medical art, Guy s Hospital, and the constant help that Mr E Engel has given us in the provision of photographs for teaching purposes

SIGNIFICANCE OF CONVULSIONS IN CHILDREN WITH PURULENT MENINGITIS

CHRISTOPHER OUNSTED
M A, B M Oxfd, D C H

PÆDIATRIC RESEARCH ASSISTANT, OXFORD REGIONAL HOSPITAL BOARD

EFFICIENT chemotherapy has dramatically reduced the mortality from purulent meningitis Swift and complete elimination of the infecting organism usually leads to permanent cure Nevertheless, purulent meningitis still carries a definite mortality, particularly in younger children The report to the Department of Health for Scotland (1944) on meningococcal meningitis showed that mortality in children aged less than one year was still 28 3%, whereas in young adults it was only 2 6% Pneumococcal meningitis still carries a grave prognosis, even when the most thorough treatment is given Jackson (1950) reported 24 fully treated cases with 7 deaths (mortality 29%) Jackson comments that the cause of death in these patients was not obvious

Severe epileptiform convulsions are a common complication of purulent meningitis in childhood and may be partly responsible for the maintenance of the mortality Their prophylaxis and treatment may play an important rôle in determining the outcome of the meningitis Hippocrates, born about 460 B C, commented on the grave significance of convulsions during brain fever, and Rilliet and Barthez (1884) said of these seizures “ Elles sont remarkables alors par leur intensité, elles se répètent coup sur coup jusqu' à la mort ” At the beginning of the penicillin era the Oxford workers emphasised the dangers of status epilepticus in infants with pneumococcal meningitis in these words “ Fits are as dangerous to the infant as the toxæmia of the infection, and their prevention or control is imperative ” (Smith et al 1946)

MATERIAL

This report concerns 90 consecutive cases of purulent meningitis admitted to the children's departments of the United Oxford Hospitals between November, 1946, and March, 1950, which received the chemotherapy appropriate for the infecting organism Children who did not receive the appropriate chemotherapy, and children with tuberculous and non bacterial meningitis were excluded

The causal organisms were meningococcus (56 cases), *Hæmophilus influenzæ* (17 cases), pneumococcus (11 cases), β hæmolytic streptococcus (2 cases), *Staphylococcus aureus* (1 case), *Staph albus* (1 case), *Bact coli* (1 case), and *Bact paracoli* (1 case)

The results were assessed in terms of the immediate outcome of the acute illness as “ cured ” or “ failed ” Failure was recorded only when the child died or was left with gross cerebral damage all other children were classified as “ cures ” This division takes no account, therefore, of residual lesions apart from cerebral damage or of cerebral lesions too small for immediate clinical detection Similarly, a child was recorded as having had a fit only when a clear record of convulsive seizure was made in the notes It follows that the

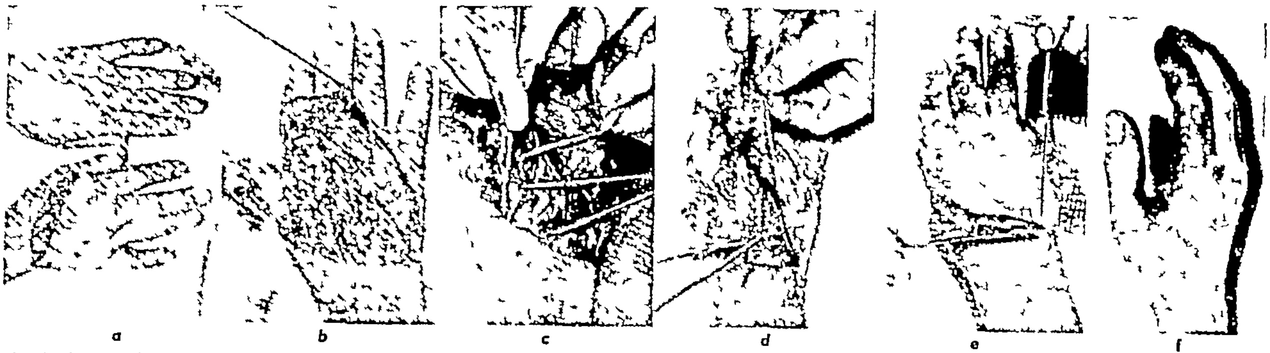

Fig 4—Some of the photographs displayed on the wall of the preparation room for the guidance of dressers *a*, avulsion of flap from dorsum of hand *b* exploration of wound after injection of local analgesic *c*, undermining with no 15 blade *d*, conversion of devitalised portion of flap into free skin graft by removal of deep surface fat , *e*, closure using Gillies s needle-holder, Gillies s hooks, and fine silk sutures , *f* results at first dressing at end of a week

A uniform system of documentation, including diagrams of the lesion, is used in all cases These records are periodically analysed, and the results made available to dressers Special care is taken to make certain that any adverse result seen in the postoperative stage is immediately brought to the attention of the dresser who did the job , such cases are made the subject of a thorough inquiry

OPERATIONS

The dressers are taught the policy of the surgery, which is that every open wound, however small, should be given a full dress surgical treatment, and that, if the full thickness of the skin has been divided, simple application of a dressing is inadequate care The chart on the wall of the theatre describes the steps taken in operating on all open wounds as follow

(1) *Toilet*, primary and secondary, with 1% cetrimide
(2) *Local analgesia* (*precautions to be taken in digital blocks*, use of ring tourniquet)
(3) *Exploration* and determination of anatomical extent of lesion
(4) *Excision* and/or debridement
(5) *Hæmostasis*
(6) *Closure* by approximation with or without undermining, by free graft, or by flaps, local or distant
(7) Aftercare

The *primary* toilet with 1% cetrimide is done, in hand and digital injuries, by the patient himself, wearing a mask and using a nail brush and nail file

We believe that a ring block analgesia with 2% procaine is safe, provided no adrenaline is added Over 3000 ring blocks have been given to date without complication

Our teaching is that all wounds, except those due to crush injuries, should have a minimal marginal excision to provide non bevelled non contaminated edges which can be accurately apposed After the wound has been excised these lacerations are accurately closed Crush injuries of the digits, on the other hand, are treated by debridement—i e , toilet and excision only of devitalised and grossly soiled tissues Suture in these cases is limited to that necessary for maintaining flaps in anatomical position The exploration and excision of digital wounds is done under a tourniquet, which is released when the latter is complete The finger is next elevated and compressed with dry gauze for 2–5 minutes Spurting vessels are clipped and twisted , if they still spurt they are ligatured Ligature material coarser than 3/0 catgut or 4/0 silk is never used in the hand If a general ooze still continues to obscure the field the tourniquet is reapplied, closure completed, the tourniquet released, and manual pressure applied over the dressing for 2–5 minutes In closure avoidance of tension and tentage is emphasised This generally means undermining with a no 15 blade while the edges are steadied with a Gillies tissue hook Tentage is avoided in the deeper wounds by a layered closure, using 3/0 catgut sutures with the knot tied on the deep surface of the flap 4/0 interrupted silks are used for skin suture , each edge is transfixed separately , the sutures are 3 or 4 mm apart, with bites of tissue 3 or 4 mm in width and depth Free grafts are generally of thin split skin, cut from the forearm with a Blair blade Full thickness grafts and local thenar and palmar flaps are cut to an accurate pattern of the defect , great attention is paid to the repair of the secondary defects in these operations

The dressing of a finger must be snug and secure with the finger semiflexed It is mainly of dry gauze kept in position with strips of zinc oxide strapping and minimal bandage We have found 'Nylon' derivative to be the best intimate dressing for lacerations This is a flexible transparent membrane that does not injure the tissues and is permeable to water vapour but impermeable to water If it cannot be obtained, tulle gras, with as little grease as possible is used

The patient is seen on the day after operation , if the dressing is in place and comfortable, he is not seen again for a week, and then most of the sutures are removed

The programme outlined above may be held to be too elaborate for some of the injuries to which it is applied, but its routine use has two advantages (1) a uniform standard of quick quiet healing can be obtained for all finger injuries treated , and (2) full advantage is taken of the training in technique that such repairs can provide

MATERIAL AND RESULTS

Nearly 3000 repairs a year are done in the outpatient accident theatre at Guy's Hospital A little under 50% of these are open digital injuries The range of work undertaken in the outpatient accident theatre covers all *open injuries of digits, with and without* tissue loss, including traumatic amputations, divisions of extensor tendon, and injuries of digital nerves, but excluding the repair of flexor tendons divided within the fibrous theca

Results in two series analysed are given here † The first series comprises 357 consecutive open digital injuries treated in three months in 1948 and including compound fractures, traumatic amputations, and injuries of extensor tendons During this period no case of isolated digital injury was admitted to the wards The second series is of 118 traumatic amputations of the finger tip treated in fifteen months The average healing time of the 357 open digital injuries was 10 2 days for lacerations without tissue loss , 18 6 days for crush injuries without tissue loss , and 15 3 days for the whole series of 357, including those with tissue loss fracture, and tendon and nerve injury The criterion of healing was that the wound was free from scab and dressing In this series healing was

† These form the subject of a separate detailed report written with Dr D O Douchar and to be published later

TABLE VI—RELATION BETWEEN FAILURES AND PHENOBARBITONE

—	Cures	Failures	Total
Phenobarbitone given	42	7 (*14%*)	49
Phenobarbitone not given	14	10 (*42%*)	24
Total	56	17	73

χ^2_1 (Yates's method) = 5.315) P is less than 0.05

and that there is in this group a parallel reduction in the incidence of convulsions (table VII). In the group treated with phenobarbitone the failure rate was 14%, and 10% had convulsions after admission to hospital; in the group not treated with phenobarbitone the failure rate was 42%, and 33% of the children had convulsions in hospital (tables VI and VII).

There seems, then, to have been a downward trend in the incidence both of seizures and of failures following the introduction of prophylaxis with phenobarbitone.

Status Epilepticus

Status epilepticus was diagnosed when a series of seizures occurred in which the coma of one seizure merged with the acute phase of the next. Status epilepticus developed in 8 patients, of whom 7 died. The causal organisms in these children were meningococcus (4 cases), pneumococcus (3 cases), and β hæmolytic streptococcus (1 case). Only 1 of these children had been given prophylactic phenobarbitone before the onset of the first seizure.

Phenobarbitone, paraldehyde, and chloral were used in various combinations to treat the established status epilepticus in the 7 fatal cases. The solitary survivor was treated with intramuscular sodium iso amyl ethyl barbiturate ('Sodium amytal'), but this child, alive twelve months later, is mentally deficient.

TABLE VII—RELATION BETWEEN FITS AND PHENOBARBITONE

—	No fits in phase II	Fits in phase II	Total
Phenobarbitone	44	5 (*10%*)	49
No phenobarbitone	16	8	24
Total	60	13	73

χ^2_1 (Yates's method) = 4.414 P is less than 0.05

The ages of these 8 children ranged from five weeks to two and a half years, average twelve months, and it was considered that all the 8 cases were failures. Nearly half the failures in the group aged less than four years were therefore associated with status epilepticus.

Delayed Sequelæ

Of the 72 children discharged as "cured," 65 were followed up as outpatients. The shortest period of study was six months. None of the children who escaped seizures have yet developed signs of permanent cerebral damage. Of the 12 "cures" who had had multiple seizures in the acute phase, 1 has since developed recurrent convulsions and 1 other has severe mental defect. If these children are classified as failures, the argument that multiple seizures are dangerous is correspondingly strengthened. Thus 17 of the 20 failures had multiple fits and 17 of the 27 children with multiple fits did not recover completely.

DISCUSSION

Prognosis

The findings of this survey show that, in cases of purulent meningitis in childhood receiving adequate chemotherapy, there is a close association between the occurrence of fits and the outcome of the disease. Bloor (1950) made a follow-up study of a series of children treated for *H. influenzæ* meningitis, and found that convulsions were the only prognostic signs of value. He found that the generally accepted criteria of severity in the acute phase bore little relation to the ultimate results; but, of those cases classified as failures, convulsions had occurred in 71%, whereas among the cured children the incidence of convulsions in the acute phase was 18%. In Jackson's (1950) series of cases of pneumococcal meningitis convulsions occurred in the great majority of the fatal cases. There is, to my mind, little doubt that seizures are prognostic signs of great importance in this group of diseases.

It may be noticed, in passing, that the prognostic significance of convulsions is not peculiar to meningitis in childhood. A similar relationship was found in infants with pneumonia (Dr. V. Smallpeice, personal communication).

Diagnosis

Attention has been drawn to the difficulties that attend the diagnosis of meningitis in early childhood (Jackson 1950, Smith 1951). Physical signs are often unreliable, and this is particularly true when the child has just had a fit. Seizures occurred in nearly half the younger children in this series and are therefore themselves diagnostic signs of some importance. Early, and hence successful, treatment of purulent meningitis depends on the prompt identification of the causal organism in a specimen of cerebrospinal fluid. It follows that any small child who has had an *unexplained* febrile seizure should be admitted to hospital, and that, unless some definite contra-indication exists, a lumbar puncture should be done without delay. By following this rule 4 hitherto unsuspected cases of purulent meningitis have been diagnosed in our department in the last three months.

Prophylaxis

Phenobarbitone as prophylaxis is given on a weight/age dosage (Ounsted 1949). A flexible schedule of dosage is used because children who have already had a fit are likely to require, weight for weight, a greater quantity of drug. For a child aged one year, weighing 24 lb., who is gravely ill, an initial dose of gr. $^1/_2$ of soluble phenobarbitone may be given by intramuscular injection. Gr. $^1/_4$ six-hourly may be given thereafter for the next thirty six hours, by mouth or by injection, and then gr. $^1/_4$ thrice daily for the remainder of the acute phase of the illness.

It is an advantage if the initial injection can be given by the family doctor, before the child is subjected to the strain of a long ambulance journey; 4 children in this series had convulsions during their journey from home to hospital.

Toxic effects from phenobarbitone in this dosage are, in my experience, almost unknown, nor have I seen any evidence of masking of the physical signs.

Treatment

The treatment of convulsions and status epilepticus is unsatisfactory in small children with purulent meningitis. The usual sedative drugs, such as chloral, phenobarbitone, and inhalant anæsthetics, are in our experience valueless. Whitty and Taylor (1949) have shown that paraldehyde by the intramuscular and intravenous routes is highly effective in controlling status epilepticus. It has, however, certain disadvantages when used for the treatment of gravely ill infants. Intravenous infusions in these children are often difficult and may be dangerous. Intramuscular injections may take half an hour to have effect—a time lag of greater danger in convulsing infants than in the older person. The children in this series in whom status epilepticus was treated with paraldehyde did not survive. Search for a possible alternative for use in this particular group seemed reasonable.

TABLE I—RELATIONSHIP BETWEEN FITS AND FAILURE OF TREATMENT

—	Cures	Failures	Total
No fits	51 (*96·2%*)	2 (*3·8%*)	53
Fits	21 (*56·8%*)	16 (*43·2%*)	37
Total	72	18	90

χ^2_1 (Yates's method) = 18·81 P is less than 0·001

incidence of fits given in this survey is the lowest true convulsion rate, whereas the incidence of cures is the highest probable cure rate.

RESULTS

In the series as a whole, 18 children died or were left with gross cerebral damage, an immediate failure rate of 20%.

Table I shows the over all incidence of convulsions in failed and cured groups. It will be seen that 37 children (41%) had fits in the course of their illnesses. In this group of children with fits the failure rate was 43%, whereas in the group free from fits the failure rate was 4%. The value for χ^2 on the absolute figures is 16·56, and the difference is therefore of high statistical significance.

Single and Multiple Fits

Table II sets out the series divided into those with no fits, those with a solitary fit, and those with multiple fits. It will be seen that the treatment failed in 3·8% of children who had no fits, 10·0% of children with only one fit, and 55·5% of children with multiple fits. The prognostic march is clear.

TABLE II—RELATION BETWEEN INCIDENCE OF FITS AND FAILURES

—	Cures	Failures	Total
No fits	51	2 (*3·8%*)	53
1 fit only	9	1 (*10·0%*)	10
Multiple fits	12	15 (*55·5%*)	27
Total	72	18	90

Age

The tendency to seizures in febrile diseases of all types is much greater in children aged less than four years than in older patients (Lennox 1949, Bridge 1949). Table III shows the series divided into those older and those younger than four years. There were 17 children aged more than four years, and of these 2 (12%) had fits; of the 73 children aged less than four years 35 (48%) had fits. Age is clearly a factor in the convulsions provoked by meningitis as in the other febrile convulsions of childhood.

In table IV only the children aged less than four years are considered. The average age of this group of children was thirteen months. The relationship between failure and the occurrence of seizures is essentially that found in the group as a whole. The following points emerge from the table:

(i) Half the children aged less than 4 years had fits.
(ii) Only 1 of the 17 failures escaped convulsions.
(iii) 37 of the 56 cured cases escaped convulsions.
(iv) Of the total of 38 who escaped convulsions 37 (97%) were cured.

TABLE III—RELATION BETWEEN FITS AND AGE

Age	Fits	No fits	Total
More than 4 yr	2 (*11·8%*)	15 (*88·2%*)	17
Less than 4 yr	35 (*47·9%*)	38 (*52·1%*)	73
Total	37	53	90

χ^2_1 (Yates's method) = 6·037 P is less than 0·05

The value of χ^2 on table IV is 18·93; the differences are therefore of high significance.

Early and Late Fits

Convulsions may occur at any time during meningitis in childhood. Inspection of the records of the present cases suggested that seizures occurring after the institution of hospital treatment were more ominous than those limited to the early days of the disease.* To examine this point more closely the illnesses of the 37 children with fits were divided into two phases. Phase I was the time from the onset of symptoms to the time when the child's admission to hospital and initial examination were complete; phase II covered the remainder of the illness.

TABLE IV—RELATION BETWEEN FITS AND FAILURES IN CHILDREN AGED LESS THAN FOUR YEARS

—	Cures	Failures	Total
No fits	37	1	38
Fits	19	16	35
Total	56	17	73

χ^2_1 (Yates's method) = 16·73 P is less than 0·001

Table V sets out the figures. 24 children had fits only in phase I and had no further attacks while in hospital; in this group 18 out of 24 (75%) were cured. 13 children had convulsions during phase II; in this group, in contrast, only 3 out of 13 (23%) were cured. Thus it seems that the fits of the second phase carry the graver prognosis. However, the possibilities of prophylaxis and treatment are greater in the second phase, since the child is under controlled conditions in hospital.

Phenobarbitone Prophylaxis

During the years covered by this survey the practice of giving phenobarbitone as a routine prophylaxis against convulsions was gradually introduced into our department.

Among the 73 children in the series aged less than four years, 49 were given phenobarbitone as a routine throughout the acute phase of their disease and 24 had no such prophylaxis. It must be emphasised that these two groups were not planned as deliberate controls and that, therefore, any conclusions drawn from tables VI and VII must be tentative. In the most recent cases a larger proportion of patients were given phenobarbitone, compared with the earlier part of the series. On the other hand, inspection of the records showed that children who had had convulsions before admission were more often given phenobarbitone than those who had not, and more likely to have further fits than those who had not had fits before admission. These facts may weight the figures slightly against the group treated with phenobarbitone.

TABLE V—RELATION OF FAILURES TO TIME OF ONSET OF FITS

—	Cures	Failures	Total
Fits before admission only	18	6	24
Fits after admission	3	10	13
Total	21	16	37

χ^2_1 (Yates's method) = 7·268 P is less than 0·01

It will be seen that the cure-rate is decidedly higher in the group treated with phenobarbitone (table VI).

UNIVERSITY OF MANCHESTER

the two years since Gaisford and Evans (1949) orted on the use of hyaluronidase as an aid to parenl administration of fluid to infants and children, s enzyme has been widely used, but its efficacy has ied. We discuss here some of the possible reasons for variation and suggest methods for improving the ults.

The first and most important cause of these differences the uncertain potency of the preparation used, which y vary within wide limits. The second is the technique administration. A third is failure to recognise the itations of hyaluronidase.

METHOD OF ASSAY

One of the clinical difficulties in judging the potency any particular specimen of hyaluronidase is that ccess or failure of absorption is evident only after jection. *A reliable method of assay in terms of a suitable* andard is essential to ensure that the preparation used active and the dosage adequate. Standardisation of yaluronidase by its method of preparation—e.g., from estis or semen—is unwise and becomes unnecessary if a eliable assay is available.

The potency of hyaluronidase preparations may be etermined by examining their diffusing activity in the kin, their action on hyaluronic acid, or their ability to ecapsulate streptococci (McClean 1942, 1943, Kass and eastone 1944, Fulton et al. 1948). A new method has been devised (Burnet 1948) which depends on the diminution in the viscosity of synovial fluid which hyaluronidase effects. This has been called the ACRA test (acid, Congo red, and alcohol are used in the indicator system). A modification of the test has been described by Oakley and Warrack (1951).

We have investigated the ACRA test, using horse synovial fluid, for its value in assaying the potency of bull testicular hyaluronidase preparations. Two methods of assay have been studied. In the first, preparations of hyaluronidase were titrated to determine the minimal reacting dose and, in the second, preparations were titrated to determine the dose which was just *neutralised* by a standard amount of antihyaluronidase.

Determination of Minimal Reacting Dose

Each sample of horse synovial fluid was first titrated to determine the most suitable dilution to use. Serial dilutions in borate buffer (Glenny et al. 1928) were incubated at 37°C for half an hour and then cooled at 4°C for ten minutes, when 0.2 ml. of 2% aqueous solution of Congo red was mixed with 0.75 ml. of each dilution. With each mixture a drop from a Pasteur pipette was allowed to fall gently into a petri dish filled to a depth of 5 mm. with acidified aqueous alcohol (1 ml. conc. HCl + 100 ml. 70% alcohol), and the minimal concentration of synovial fluid which gave a coherent blue globule was determined. Six times the minimal concentration was chosen as the indicating dose in the hyaluronidase activity tests, so that excess of substrate was ensured.

In testing the potency of hyaluronidase *preparations* a series of dilutions of hyaluronidase in borate buffer was made, and to 0.5 ml. of each dilution six indicating doses of synovial fluid in 0.25 ml. were added. The mixtures were incubated at 37°C in a water bath for half an hour and *cooled at 4°C for ten minutes*. To each *mixture* 0.2 ml. of 2% aqueous solution of Congo red was added, and with a Pasteur pipette drops of each mixture were allowed to fall gently into acidified alcohol.

With those mixtures containing an insufficient concentration of hyaluronidase to affect the viscosity of the synovial fluid the drop remained as a coherent blue globule, but with those containing hyaluronidase in sufficient concentration to reduce the viscosity the drop diffused into the acid alcohol and stained blue. The minimal dilution of hyaluronidase which gave a definite diffuse spread was taken as the end-point and referred to as the minimal spreading dose (M.S.D.).

Various preparations of hyaluronidase were titrated by this method at 25% differences between the dilutions, different samples of synovial fluid being used. A typical set of results is given in table I. As was expected, different end points were obtained with the different samples of synovial fluid for any one preparation of hyaluronidase, but the order of increasing activity of the preparations was the same with each sample of synovial fluid—i.e., H2, H1, H3, H4. The ratios of the activities, however, were not always the same, and because of this the potency of any one preparation, if assayed in terms of a standard hyaluronidase, would vary in different tests. The difficulties involved in determining with a high degree of accuracy the minimal reacting dose of enzymes or toxins are well known, because end points in such tests are not sharply defined. It was because of these considerations that the neutralisation method was investigated.

TABLE I—POTENCY OF HYALURONIDASE PREPARATIONS, WITH DIFFERENT SAMPLES OF SYNOVIAL FLUID ASSAYED BY DETERMINING MINIMAL REACTING DOSE (M.S.D.)

Preparation of hyaluronidase	Titres (M.S.D.) with four samples of synovial fluid			
	SF1	SF2	SF3	SF4
H1	1/100	1/80	1/400	1/400
H2	1/25	1/16	1/100	1/100
H3	1/2000	1/1000	1/4000	1/4000
H4	1/6500	1/6500	1/7000	1/7500

Determination of Neutralised Dose

Antisera to bull testicular hyaluronidase were prepared in rabbits by giving weekly injections of hyaluronidase for six months. The earlier injections were given subcutaneously and the later ones intravenously, and each dose contained about 5000–6000 M.S.D. The antisera were tested for neutralising potency by determining the lowest dilutions which neutralised the activity of 20 M.S.D. of hyaluronidase. The most potent antiserum prepared was such that 1 ml. neutralised almost 32,000 M.S.D. of enzyme.

In testing the potency of hyaluronidase preparations a high titred antiserum was chosen and given the arbitrary value of 800 units per ml. Determinations were made of the dilution of hyaluronidase neutralised by 1 unit of antihyaluronidase, and the potency was expressed in terms of the number of units required to neutralise 1 ml. of undiluted preparation. A series of dilutions of hyaluronidase was made, and to 0.25 ml. of each dilution 0.25 ml. of 1/200 dilution of antiserum (1 unit) was added, and the mixtures were left at room temperature for an hour to allow neutralisation to occur. The appropriate dilution of synovial fluid (six indicating doses in 0.25 ml.) was then added, and the mixtures were incubated at 37°C for half an hour, followed by cooling at 4°C, when 0.2 ml. of Congo red solution was added, and drops of each mixture were tested in acidified alcohol. The end-

There was thus little evidence of cross infection in this virtually closed community, though the investigation was necessarily limited

Sensitivity tests were done on the 21 potentially pathogenic organisms isolated during these studies, the findings are shown in table IV Tube tests were made, doubling dilutions of each antibiotic in broth being infected with standard inocula from 7 hour broth cultures of the organisms The results were read by visual estimation of turbidity after overnight (sixteen hours) incubation Controls consisted of an Oxford staphylococcus and a local strain of β hæmolytic streptococcus

" Penicillin sensitive " strains all showed sensitivity equal to or greater than that of the Oxford staphylococcus, " penicillin resistant " strains were more than sixteen times as resistant as the Oxford staphylococcus (all of the 6 resistant staphylococci tested were penicillinase producers) " Streptomycin sensitive " strains were sensitive to 16 µg per ml or less, 2 strains, shown in parentheses in the " resistant " column of the table, resisted 16 µg but were inhibited by 32 µg per ml, and the remaining " resistant " organism resisted 32 µg but was sensitive to 64 µg per ml " Chloramphenicol sensitive ' strains were all inhibited by 13 µg per ml or less, " resistant " strains both resisted 25 µg but were sensitive to 50 µg per ml " Aureomycin sensitive " strains were all sensitive to 2 µg per ml or less, the 3 gram negative strains graded as "? resistant" resisted 6 25 µg but were inhibited by 12 5 µg per ml of aureomycin under the conditions of the test

These tests with aureomycin are of uncertain significance, but the sensitivity tests do suggest that most of the potentially pathogenic organisms isolated from the patients and their environment were sensitive to the antibiotics used

DISCUSSION

The outstanding value to the smallpox patient of previous successful vaccination is again illustrated in this small outbreak Variations in response to infection, as shown by the length of the incubation period, the severity of prodromal illness, and the extent of the rash, are presumably individual manifestations depending on the rapidity and adequacy of the immune response in both vaccinated and unvaccinated persons In this epidemic, though such factors as the degree of exposure, age, and state of nutrition were similar in all the fatal cases in adults, no two of these patients presented identical pictures Individual variations in antibody levels have been found by Collier and Schonfeld (1950) to be correlated with severity and mortality in smallpox The equivalent severity of the prodromal stages in both vaccinated and unvaccinated groups suggests that, until the stage of secondary viræmia is initiated, there is little individual difference in response to infection by variola virus, if clinical smallpox is to be the outcome The subsequent course probably depends on the degree to which circulating antibodies neutralise virus liberated into the blood stream from internal sites of multiplication When neutralising antibodies are present in high titre, viræmic spread cannot occur, and no rash will appear, when they are moderate in amount, antibody neutralisation reduces the amount of active virus disseminated, and further modification of the disease results from additional antibody production by a host already trained to produce it Collier and Schonfeld (1950) found a more rapid rise in antibody level in vaccinated than in most unvaccinated persons In a non immune host with no basal antibody the course of smallpox will depend on the balance between the speed of multiplication and spread of the virus and the inherent ability of the host to produce antibody Delayed or inadequate immune response allows virus to invade and damage such a high proportion of the host's cells as to impair vital functions and cause death

The effects of the antibiotics used in treatment were disappointing inasmuch as they exerted no effect on the expected mortality Nevertheless clinical and bacteriological observations showed that secondary bacterial invasion of the skin lesions was minimised, so that no " pustular " stage and no classical " secondary fever " was seen Abacterial necrosis was followed by liquefaction of the cells involved in the lesions, the formation of bullæ, and desquamation of large areas of skin The distressing respiratory symptoms suggested that similar changes might be occurring in the trachea and smaller air-passages The continuance of pyrexia in at least two typically confluent cases might well be explained by loss of active skin surface How much the toxæmia resulting from extensive skin damage contributed to death is uncertain, for myocarditis had already developed in the earlier stages The nature of the cardiac damage is not known, but it may well have been due to virus invasion The inability of antibiotic therapy to influence the virus pathology of the disease might be related to failure to administer these preparations before viræmic spread and widespread cellular invasion had occurred, but there is no evidence at present to suggest that variola virus is susceptible to any antibiotic yet known (Eaton 1950)

In view of the obvious cardiac damage, it was our impression that the utmost attention should be paid to the problem of how best to nurse smallpox patients in future epidemics, so that such complications may be minimised Supportive measures—e g, early blood transfusions and, in some cases, administration of 'Eucortone' and vitamin K—may be advantageous, especially in females, because hæmorrhage and toxæmia rapidly cause weakness which may be fatal, as in the present series Dixon (1948) remarked that the " blunderbuss " therapy advocated by Boeck (1946) did not seem to be beneficial, yet the severe case is in such a serious state that all possibly effective measures are called for

The value of laboratory examinations in diagnosis was again demonstrated The primary case in this epidemic was considered to be chickenpox on what still seem, in retrospect, the most convincing clinical grounds, and yet the application of appropriate diagnostic techniques, as discussed by MacCallum et al (1950), would have revealed the true nature of this illness in time for protective vaccination a week or so earlier than was the case It seems reasonable to suggest that facilities for prompt laboratory investigation of cases in which there is the faintest possibility of smallpox—e g, in recent arrivals in this country from any infected region—should be available in all areas

SUMMARY

Some of the important clinical aspects of smallpox (variola major) are described, from a study of 17 patients

Attention is directed to the importance of cardiac damage in severe cases

Antibiotics had no effect on the virus, but greatly modified secondary bacterial infection of the skin lesions

We wish to thank Prof A W Downie for his assistance in the virus studies, and Dr R E O Williams for phage typing the staphylococci

SUMMARY

A method is described by which the potency of testicular or seminal hyaluronidase, prepared for therapeutic purposes, may be assayed by determining the quantity neutralised by a standard amount of specific antihyaluronidase

The clinical indications and methods of using the enzyme are outlined

We wish to thank Dr C L Oakley and Miss G H Warrack, of the Wellcome Research Laboratories, for helpful advice and for many samples of synovial fluid, and Dr D Riding, of the Evans Biological Institute, Dr F Fletcher, of Bengers Ltd, and Dr F A. Robinson, of Allen & Hanburys Ltd, for the hyaluronidase preparations

CONCENTRATION OF PENICILLIN IN THE LUNGS

EFFECTS OF TWO PENICILLIN ESTERS IN CHRONIC PULMONARY INFECTIONS

A G S HEATHCOTE
M.R C S
SENIOR REGISTRAR IN PATHOLOGY

E NASSAU
M.D Vienna
PATHOLOGIST

HAREFIELD HOSPITAL MIDDLESEX

As a rule penicillin administered systemically does not reach the sputum in effective concentrations, and for this reason the scope of penicillin therapy in chronic pulmonary infections has been limited We have, however, been investigating two new penicillin derivatives which Prof. K A Jensen and other workers (1950) in Copenhagen had found to be excreted to an unusual extent through the lungs

This valuable property was discovered by Jensen and his colleagues in the course of their search for new insoluble penicillin compounds having a "depot" action like that of procaine penicillin, a dose of which injected intramuscularly gradually releases penicillin into the blood stream They found that an ester of penicillin —benzylpenicillin diethylaminoethylester hydriodide (L G 1)—gave a satisfactory depot effect, though equal doses of procaine penicillin usually produced higher blood penicillin levels for longer periods When they came to investigate the fate of L G 1 in the tissues of laboratory animals, however, they observed that the penicillin level produced in the lungs by equal intra muscular doses was several times higher with L G 1 than with either sodium penicillin or procaine penicillin Preliminary observations in man confirmed this peculiarity of L G 1 and seemed to justify the hope that it would prove more effective than other penicillin preparations in the treatment of pulmonary infections

MATERIALS AND METHODS

L G 1 is a white crystalline powder, said to be soluble in water at room temperature only to the extent of 1 part in 96, so that a saturated solution would be equivalent to about 10,000 units per ml. It was supplied in the form of a dry powder, to be prepared for injection by adding sterile water and shaking, so producing a suspension which could easily be injected intramuscularly

We have also studied the hydrochloride of benzylpenicillin diethylaminoethylester (L G 2), which is much more soluble in water than L G 1

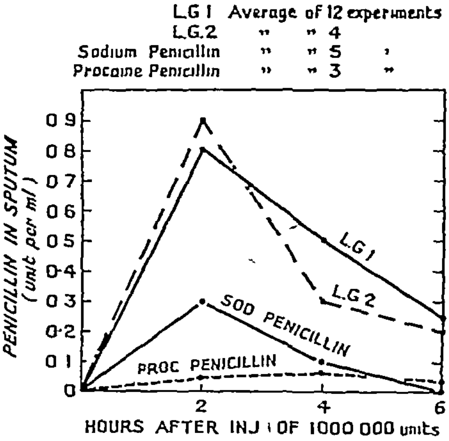

Fig 1—Penicillin levels in sputum after intramuscular *doses of 1,000 000 units of penicillin in form of L.G 1* **L.G.2 sodium penicillin or procaine penicillin in same patient.**

Patients with chronic non tuberculous pulmonary conditions were selected for treatment To avoid difficulties arising from the admixture of saliva with the sputum, only patients producing copious sputum—i e, cases of bronchiectasis, lung abscess, and suppurative pneumonitis—were chosen for the trial. Patients who had not received chemotherapy for a long time, if at all, were preferred

Since the standard dosage of crystalline sodium penicillin at Harefield Hospital is 1,000,000 units every 12 hours, L G 1 and L G.2 were given in the same dosage Other patients received procaine penicillin in aqueous suspension, or sodium penicillin in aqueous solution

In some experiments specimens of sputum were obtained at 2, 4, and 6 hours after the injection and assayed for penicillin In other experiments the sputum was collected over the 24 hours, measured, homogenised, and assayed. Before treatment a 24 hour specimen was measured and examined bacteriologically Bacteriological examinations were also made during and after treatment The penicillin compounds were always given intramuscularly The course of treatment with L G 1 and L.G 2 lasted 1 week in each case

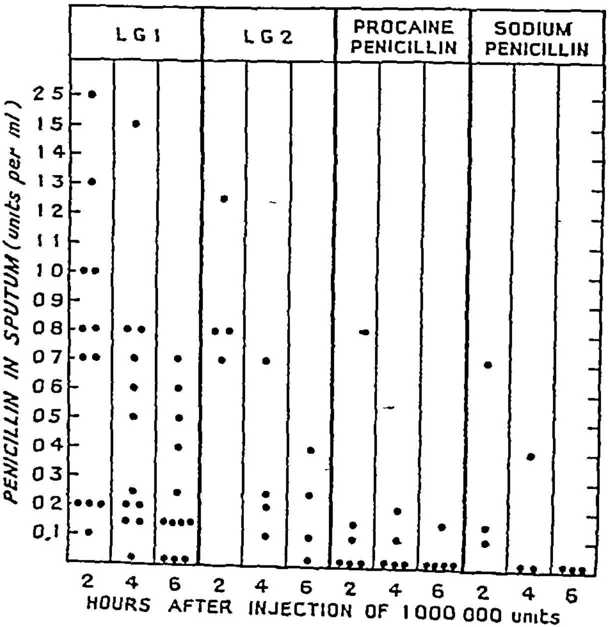

Fig 2—Penicillin levels in sputum after intramuscular doses of 1 000 000 units of penicillin in form of L.G 1 L.G.2 sodium penicillin or procaine penicillin in different patients.

TABLE II—POTENCY OF HYALURONIDASE PREPARATIONS, WITH DIFFERENT SAMPLES OF SYNOVIAL FLUID, ASSAYED BY NEUTRALISATION WITH ANTISERA

Preparation of hyaluronidase	Potency with three samples of synovial fluid		
	SF8	SF9	SF10
H1	16 (1/4)	18 (1/4.5)	16 (1/4)
H4	500 (1/125)	500 (1/125)	600 (1/150)
H5	56 (1/14)	48 (1/12)	48 (1/12)
H6	44 (1/11)	40 (1/10)	40 (1/10)
H7	56 (1/14)	48 (1/12)	48 (1/12)

The potency of a preparation is expressed in terms of the number of arbitrary units of antihyaluronidase required to neutralise 1 ml of the undiluted preparation. The dilutions of hyaluronidase (0.25 ml volume) at which the end point occurred with 1 unit of antihyaluronidase are given in parentheses.

point in this titration was read as the most concentrated dilution of hyaluronidase that was completely neutralised by antiserum and thus gave a coherent globule.

Results are given (table II) showing the potency of five different preparations of hyaluronidase when tested by this method with three samples of synovial fluid. Titrations were made with hyaluronidase dilutions which differed by 10–20%. It was evident that this test could, with different samples of synovial fluid, not only arrange the enzyme preparations in the same order of activity but also give potency values which agreed very closely. The end points were well defined and easier to read than those obtained in determining the minimal reacting dose.

Diffusing Activity in Skin

The examination of the diffusing activity in the skin is not a satisfactory method of determining quantitatively the potency of hyaluronidase preparations (McClean and Hale 1941). Since, however, the material was to be used for increasing the permeability of tissues to injected fluids, it was considered desirable to ascertain whether there was a correlation between diffusion in the skin and the ACRA test.

Diffusing activity of hyaluronidase preparations was tested by injecting intradermally 0.2 ml of each of a series of tenfold dilutions into depilated guineapigs. The end point was taken as that dilution giving a bleb which had entirely disappeared in ten minutes.

The activity of five hyaluronidase preparations was examined by the skin test in parallel with the ACRA test.

TABLE III—RELATION BETWEEN SKIN TEST AND ACRA TEST

Preparation of hyaluronidase	Skin test highest dilution producing diffusion	ACRA test M.S.D. with synovial fluid S14
H1	10^{-2}	1/120
H2	10^{-1}	1/50
H4	10^{-4}	1/6500
H5	10^{-3}	1/600
H6	10^{-3}	1/500

The results (table III) showed that the preparations fell into the same order of activity by both tests.

METHOD OF ADMINISTRATION

As regards the method of administration, the only modification suggested is a simplification of that described originally. All that is needed is a standard blood transfusion bottle and "giving" set.

With the intravenous needle attached to the set, the rate of flow is such that a two way set, as originally used, is unnecessary. The needle may be inserted in the midline above the umbilicus and directed downwards, or it may be inserted laterally just above or below the umbilicus and directed medially. The anterior abdominal wall has proved the most effective site for subcutaneous injection: the absorptive area is greater, there is less risk of sepsis, and there is less discomfort. The rate of flow after the injection of the hyaluronidase should be a continuous stream through the regulator, and it should be possible to give 100–300 ml of fluid within five minutes. The quicker the fluid is given, the more efficacious has hyaluronidase proved. It is of much less value in drip infusions.

Various techniques have been recommended. The hyaluronidase may be injected into the skin first, either intradermally or subcutaneously, and the fluid given through that site, or it may be dissolved in the infusing solution, or the solution may be injected first and the hyaluronidase added, in concentrated solution, after 2 or 3 ml have been injected. This last method has given the best results. The hyaluronidase powder is dissolved in sterile water and drawn up into a 1 ml syringe. When the flow of fluid to be injected (saline solution, saline glucose solution, or plasma) has started, the hyaluronidase is injected rapidly into the rubber tubing just above the needle inserted into the skin. The fluid injected should be cool; heat diminishes the activity of hyaluronidase. Hyaluronidase does not retain its potency long in solution; it is therefore necessary for it to be freshly dissolved to obtain the best results. The amount of diluent is of secondary importance; 0.5–1.0 ml of sterile water is usually adequate.

The conditions in which hyaluronidase has proved of particular value are severe dehydration fever in the newborn, pyloric stenosis (preoperatively when dehydration is only moderate and the general condition is good), and gastro-enteritis. For any infant who is vomiting and unable to retain sufficient fluid, and when intravenous injection is technically difficult, this method of subcutaneous absorption affords a simple alternative route for fluid administration. *However, it must be emphasised that any seriously ill, toxic, and dehydrated infant who needs parenteral fluid will need it intravenously.* The value of hyaluronidase in such cases is that it minimises the number of intravenous infusions necessary. Often only one is required; thereafter subcutaneous injection will suffice till oral feeding can be resumed.

Hyaluronidase has also proved of value in pyelography in newborn and young infants in whom intravenous injection may offer considerable difficulties. Intramuscular injection of dye does not produce very satisfactory results. Any means of successful subcutaneous injection is therefore of value. The time taken for absorption of sufficient dye to give a reasonable picture is longer than in the case of intravenous injection, but this is compensated for by the fact that the injection can be given in the ward or nursery and the infant taken down to the X-ray department twenty minutes later. This minimises the time spent in the X-ray department. For a newborn infant 5 ml of diodone, mixed with 10 ml of sterile water in a 20 ml syringe, are usually adequate. It is important that the solution should be heated as little as possible. One end of a piece of rubber tubing (part of a catheter is suitable) 2 or 3 inches long is attached to the nozzle of the syringe, and an intravenous needle is attached to the other end of the rubber. The needle is inserted into the subcutaneous tissue of the anterior abdominal wall in the region of McBurney's point and directed outwards. About 1 ml of the dye solution is injected, and then the hyaluronidase, freshly dissolved in 0.5 ml of water, is injected into the rubber tubing. The rest of the dye is then injected fairly rapidly and the needle withdrawn from the skin. Exposures are made thirty minutes after the injection and thereafter as indicated. The injection is best timed to be given shortly before a feed is due—i.e., usually four hours after any fluid has been given. The feed may then be offered in the radiological department while the exposures are being made. This may make the procedure much easier and quieter and lead to the production of better films.

symptoms suggestive of water retention after continuous infusion for five days; in addition, after the treatment he had an attack of asthma, the intensity of which gradually decreased after forty-eight hours. The majority of the infusions were followed by local thrombosis of the vein segment utilised, but many of these veins recanalised rapidly. This is a serious drawback to the method. In view of this thrombotic tendency, it was thought inadvisable to use a glucose solution as the carrying medium. In two patients extravenous leakage resulted in a red painful swelling lasting 1–4 days.

CASE-SUMMARIES

Case 1.—A man, aged 72, with psoriatic arthropathy for the past five years, preceded by localised psoriasis for thirteen years.

Severe generalised rheumatoid arthritis involving all joints except the hip and spine. Psoriatic plaques covering the feet, legs, groins, abdominal wall, back, hands, forearms, and scalp. Nails showed typical thickening. Splenomegaly and generalised adenopathy were noted.

Treatment.—A.C.T.H. intravenously in a total dosage of 225 mg. as follows:

1. A.C.T.H. 25 mg. in 1 pint 0·18% NaCl over eight hours on alternate days; 5 infusions.
2. A.C.T.H. 50 mg. in 1 pint 0·18% NaCl over eight hours; 3 infusions.

Result.—Marked improvement. All joints became non-tender and painless on movement, and the stiffness greatly decreased. Raising the hands behind the head became possible. The psoriasis largely faded, residual areas showing only skin staining without thickening or scaling; and the splenomegaly and adenopathy disappeared. After the second infusion the patient could write letters, though he had been unable to do so for over a year. The erythrocyte sedimentation rate fell from 38 mm. in the first hour (Westergren) to 5 mm. by the third infusion. The right-hand grip improved from 88 mm. Hg to 170 mm. Hg during the course. One week after treatment was stopped the psoriasis was relapsing, but the arthropathy remained improved.

Case 2.—A man, aged 27, with Boeck's sarcoidosis following erythema nodosum in May, 1950.

Lacrymal and parotid glands enlarged. No significant lymphatic adenopathy, but liver and spleen easily felt. Radiograph of chest showed typical reticulation with moderate hilar adenopathy. Diagnosis confirmed by liver biopsy.

Treatment.—A.C.T.H. in total dosage of 700 mg.—250 mg. intravenously and 450 mg. intramuscularly—as follows:

1. A.C.T.H. 25 mg. intravenously in 1 pint 0·18% NaCl over eight hours; 1 infusion.
2. A.C.T.H. 25 mg. by intramuscular injection six-hourly for three days.
3. A.C.T.H. 25 mg. intravenously in 1 pint 0·18% NaCl over eight hours on alternate days; 9 infusions.
4. A.C.T.H. 25 mg. by intramuscular injection twice daily for three days.

Result.—After the first infusion, within twenty-four hours the spleen became impalpable and the lacrymal and parotid glands greatly diminished. Forty-eight hours later the spleen was again palpable. Two weeks later A.C.T.H. 25 mg. six-hourly by intramuscular injection was started. After three days there was no noticeable clinical change. Resumption of intravenous administration was quickly followed by the spleen becoming impalpable, diminution in the size of the liver, and flattening of the facial swellings.

Case 3.—A man, aged 53, with rheumatoid arthritis for the past ten years and severe crippling since November, 1950.

Generalised arthropathy involving particularly the right knee-joint, with extreme joint tenderness, painful movement, and limitation of extension by 30°. Radiographs confirmed the diagnosis by showing generalised osteoporosis and typical joint changes.

Treatment.—A.C.T.H. in a total dosage of 1200 mg.—200 mg. intravenously and 1 g. intramuscularly—as follows:

1. A.C.T.H. 25 mg. by intramuscular injection six-hourly for ten days.
2. A.C.T.H. 50 mg. intravenously in 1 pint 0·18% NaCl over eight hours on alternate days; 4 infusions.

Result.—After four weeks' bed rest, physiotherapy, and repeated blood-transfusion, the patient's condition was improving slightly and gradually. It was decided to use A.C.T.H. in an attempt to straighten the right knee-joint. The gradual improvement previously noticed continued with intramuscular injection of A.C.T.H., and extension of the knee became possible to within 10° of the normal. There was, however, no appreciable alteration of the pain and tenderness in the joints, and he was still unable to walk. After an interval of two weeks intravenous administration was begun. Walking became relatively painless after the second infusion and continued to improve. The other affected joints became almost entirely pain-free. There was no further improvement in the range of movement of the knee-joint, probably because of adhesions.

Case 4.—A man, aged 26, with bilateral iridocyclitis which had progressed since November, 1949. In January, 1951, found to have generalised adenopathy, enlarged liver, and radiographic changes suggesting pulmonary sarcoidosis. Mild asthmatic attacks since childhood, ceasing at onset of iridocyclitis in 1949.

Previous treatment had included 'Cortisone' 25 mg. by intramuscular injection daily for ten days, and streptomycin 50 g. concurrently with subconjunctival cortisone. Both had led to slight improvement.

Treatment.—A.C.T.H. in total dosage of 950 mg.—700 mg. intravenously and 250 mg. intramuscularly—as follows:

1. A.C.T.H. 25 mg. intravenously in 1 pint 0·18% NaCl over eight hours on alternate days; 8 infusions.
2. A.C.T.H. 12·5 mg. by intramuscular injection six-hourly for three days, followed by 25 mg. twice daily for two days.
3. A.C.T.H. 500 mg. intravenously in 0·18% NaCl over five days.

Results.—Ophthalmologist's report (Mr. Goldsmith) as follows:

Before treatment: old punctate keratitis in both eyes, moderate number of inflammatory cells in the aqueous. Many vitreous opacities in both eyes. Fundi not visible in any part. Vision: rt. 3/60, lt. counting fingers at 1 metre.

After first course of A.C.T.H.: anterior segment as before. Vitreous very much clearer. Small spots of healed choroiditis visible in both eyes at the periphery. Discs not seen. Vision: rt. 4/60, lt. no change.

After third course of A.C.T.H.: still old punctate keratitis. Cells in anterior chamber present but much fewer. Many small spots probably of choroidoretinitis scattered over whole fundus of both eyes. Both discs now quite clearly seen with no abnormality. Vision: rt. 6/60, lt. 1/36.

These were the first views obtainable of the fundi for over a year.

CONCLUSION

A.C.T.H. intravenously produces a more pronounced effect than a similar dose intramuscularly. Patients having A.C.T.H. by both routes volunteered the information that there was a remarkable difference in their symptoms while on the intravenous therapy. The average dosage intravenously was 50 mg. on alternate days, compared with 25 mg. every six hours intramuscularly, thus reducing the cost to a quarter. All patients demonstrated the usual effects of A.C.T.H., including a fall in eosinophils and an immediate increase in appetite, weight, and sense of well-being.

A.C.T.H. intravenously has no apparent harmful effect apart from the local venous thrombosis already mentioned. If this treatment is continued for a long time the normal complications of A.C.T.H. therapy are presumably possible. Four more patients are at the moment under treatment by this method without any further complications.

Our thanks are due to Dr. H. L. Marriott and Mr. A. J. B. Goldsmith for permission to publish details of cases under their care, to Dr. A. R. H. Hicks of Crookes Laboratories for his encouragement and assistance, and to Crookes Laboratories, Ltd., for their generous supplies of A.C.T.H.

to determine, if possible, whether growth response was inhibited only while the organism was exposed to hyper thermia Tubes with pH 6 52 needed 168 hours' hyperthermia for complete inhibition of growth response, tubes with pH 6 98 showed complete inhibition of growth response at 120 hours, and tubes with pH 7 32 or more showed no appreciable growth response at any time (figs 3 and 4)

To differentiate inhibition of growth response from destruction of the organism to the extent that it could no longer be subcultured inoculation on Sabouraud's agar was made from each tube in this group at the end of the experiment The results of such cultures suggested that the length of the period of hyperthermia necessary to destroy *C neoformans* varied with the pH of the medium

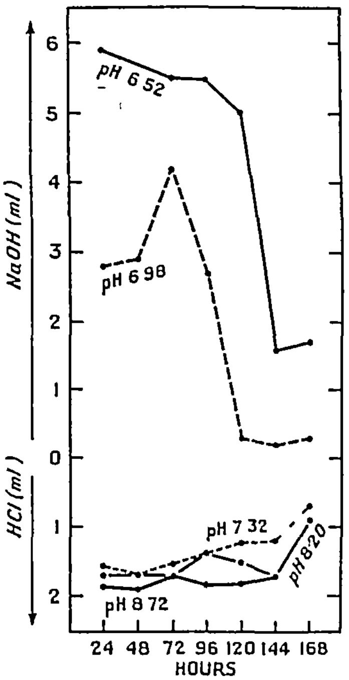

Fig 3—Effect of pH plus hyperthermia on acidometric growth response of *C neoformans* as determined 17 days after hyperthermia had ended

pH of medium	*Earliest hour at which culture showed no growth*
6 52	144
6 98	144
7 32	120
8 20	72
8 72	48

DISCUSSION

The most commonly used medium for culturing fungi is Sabouraud's agar Sabouraud's agar, which has a pH of 5 5–6 (Zinsser and Bayne Jones 1939), is preferable to other more commonly used laboratory media (pH 7 2–7 8) for the purpose of culturing fungi, because the acid reaction tends to inhibit the growth of associated bacteria (Whitby 1944), and because fungi seem to grow better on such an acid medium If an acid medium enhanced the growth of fungi, an alkaline medium might proportionately inhibit their growth This rationale led, five years ago at this clinic to the conception of alkalinisation as a means of treating patients with torula meningitis Three clinical cases of torulosis of the central nervous system were treated at the University Hospital with large quantities of alkalinising substances, and the results were published by Mosberg and Arnold (1950)

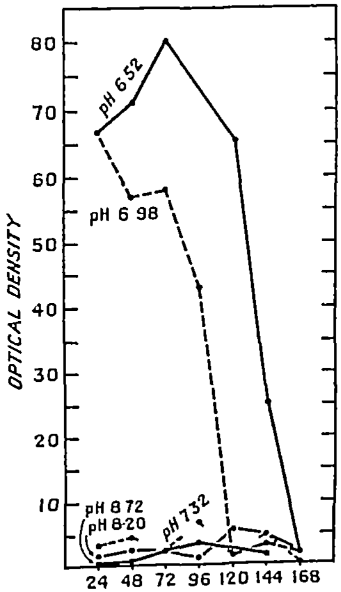

Fig 4—Effect of pH plus hyperthermia on colorimetric growth response of *C. neoformans* as determined 17 days after hyperthermia had ended

Crone et al (1937), using a 48 hour dextrose agar culture of torula suspended in 10 ml of peptone broth, pH 7 2, found that *C neoformans* was killed by heating in a water bath for 42 minutes at 50°C At 60°C it was killed in less than 5 minutes Since these temperatures were too high to be of value clinically, fever was not used therapeutically for torulosis in man Later, however, it was found that the growth of *C neoformans* could be inhibited at temperatures low enough to warrant clinical consideration if these temperatures were maintained long enough (Cox and Tolhurst 1944) A. M Kligman (unpublished experiments) has demonstrated that, with cultures of *C neoformans*, macroscopic growth is no longer visible and subculturing is impossible after five days' exposure to 40°C, three days' to 41°C, and two days' to 42°C

These facts suggest that human torulosis of the central nervous system should be treated by a combination of hyperthermia and alkalinisation

SUMMARY

pH seems to be an important factor in the growth of *Cryptococcus neoformans*

Long periods of hyperthermia seem to inhibit the growth of *C neoformans*

The length of the period of hyperthermia required to inhibit the growth of, or to kill, *C neoformans* varies with the pH of the culture medium

This work was done with the help of a grant from the Hoffberger Neurosurgical Fund

Preliminary Communication

A C T H BY INTRAVENOUS INFUSION

In order to enhance the effectiveness of A C T H therapy, a trial is being made of intravenous infusion of the hormone over periods varying from six hours to several days Hitherto the results have been remarkably gratifying Advantages that may be expected from the adoption of this route of administration are twofold (1) reasonably continuous stimulation of the adrenal glands, and (2) a considerable economy in cost

Theoretical objections to this technique are that it may cause hypertensive effects owing to contamination of the A C T H with posterior pituitary extracts, and that it may produce protein shock In no patient so far treated have these effects been observed, and it is likely that any anaphylactic effect would be counteracted by the presence of the A C T H No case in this series has been treated for longer than one month by the intravenous route, and eventual sensitisation is a possibility

MODE OF ADMINISTRATION

Infusions of 25 or 50 mg of A C T H in $^1/_2$ or 1 pint of 0 18% sodium chloride solution were given over six to twelve hours (usually eight hours) on alternate days One patient received a continuous infusion of 500 mg of A C T H in 0 18% NaCl over five days

COMPLICATIONS

No significant rise in blood pressure or pulse rate was noticed during the infusions Case 4 developed mild

THE LANCET

LONDON SATURDAY, JUNE 9, 1951

Teaching the Teacher

THE art and practice of medical teaching is a perennial subject for discussion Professional educationists are rather fond of pointing out that university teachers rarely receive any systematic instruction in exposition and rhetoric, instead they are chosen on the basis of scholarship, ability in original research, technical competence—that is, almost every quality other than those explicit in the titles professor and lecturer While this is in the main true it does not necessarily follow that they are, as a group, bad teachers Every medical school has all sorts ranging from the almost incoherent, who fail dismally to hold the attention of a class, to the gifted few whose formal lectures and clinical classes are effortless masterpieces of dramatic art

It is doubtful if there is any close correlation between teaching ability, high critical faculty, and intellectual brilliance One of the most dangerous faults in medical teaching is that the forceful and persuasive teacher may impart to his material an entirely spurious veneer of precision and finality He may take a mass of unverified observations and a series of ingenious but fanciful hypotheses, add a " hunch " or two, and present the mixture with such emphasis and apparent logic as to make it sound like a divine revelation. This is the cardinal sin of certitude which held the minds of men in bondage in the Mediæval Age of scholasticism—a heresy which still persists and which should be fought with the vigilance and vigour of the Inquisiton. In the past clinical teachers particularly offended in this respect, because many of them had insufficient or no experience of the discipline of scientific research and because the conditions of successful consultant practice so often require a pretence of omniscience that at last even the pretender is deceived At the other extreme is the teacher so oppressed by the doubts and uncertainties which beset most aspects of the theory and practice of medicine that his discourses, instead of stimulating and challenging his pupils, plunge them into a mist of confusion To steer a successful course between the Scylla of certainty and the Charybdis of confusion is the highest art of university teaching Most would agree that the aim of medical teaching is not only to instruct but to educate, in the sense that Lord MORLEY meant when he defined an educated man as one who knew when a proposition had been proved and when it had not If medical schools fail to provide such education, then doctors will be at a grave disadvantage in the community of professional men, indeed such schools will forfeit their claim to be parts of universities and will become merely technical colleges

Apart from these lofty considerations there is much that demands discussion and improvement the place of the theoretical lecture, the value of the tutorial system, the place of the young teacher, the use of visual aids, the clinico pathological conference —these and many other broad topics are important On the practical side a more systematic effort should be made to improve the standard of delivery There are still too many medical teachers who are inaudible, who bury their noses in their notes, who address their boots, the blackboard, the ceiling—anything but their audience—whose discourse is a sea of " ehs " and " ahs " with islands of words, who, while they may rise to the special occasion of a communication before a society, are casual, slovenly, and even unpunctual in their routine delivery We welcome therefore the announcement that the Postgraduate Medical School of London is holding a two day conference on medical teaching later this month Teachers from many medical schools are being invited, and there is a full programme ranging over many aspects The discussion of each subject will be introduced by a half-hour talk from one of a group of experienced teachers This enterprise cannot fail to do much good, the only drawback will be that, as with all reform movements, the preaching will in the main be to the converted

A Useful Vasodilator

ONE of the first drugs found to produce vasodilatation by autonomic blockade was 2 benzyl-4,5 imidazoline hydrochloride (' Priscol,' ' Priscoline ') Chemically, this resembles both the sympatheticomimetic amines and histamine, and it has an extremely complicated pharmacological action. In 1939, HARTMANN and ISLER[1] established experimentally that priscol lowered blood pressure and caused dilatation of the conjunctival capillaries Two years later AHLQUIST and his colleagues[2] found that it acted chiefly as a sympatheticomimetic agent, producing vasodilatation of the peripheral and coronary vessels and increasing cardiac output, and evoking histamine-like and parasympatheticomimetic effects Finally, they showed that it had an adrenolytic and a selective sympatheticomimetic antipressor action, potentiating sympatheticomimetic vasodilatator impulses

In man the effects of priscol on the circulation were studied by GRIMSON and his associates,[3] who found that the drug produced vasodilatation in the limbs when injected intravenously and to a lesser extent when administered orally In two of three patients investigated the cardiac output was unaltered, while in the third an initial high output was reduced to normal. In hypertensives large doses (100–200 mg) intravenously lowered the blood-pressure, but the results of sustained treatment were disappointing That the drug had a direct peripheral action was suggested by an increase in skin temperature in sympathectomised limbs, one side-effect was " goose flesh," which appeared even after sympathetic denervation In peripheral vascular disease the results were encouraging, but did not equal those of sympathectomy LYNN,[4] investigating the action of priscol on occlusive vascular disease and vasospastic

Reviews of Books

A Manual of Artificial Radioisotope Therapy

Editor P F Hahn, Cancer Research Laboratories,
Meharry Medical College, Nashville, Tennessee New
York Academic Press 1951 Pp 310 $6 80

In planning this survey by a group of authors, Dr Hahn has emphasised the developing scope of radio-isotope therapy by including more chapters on general principles than on particular forms of treatment The book includes some admirable sections—for example, on dosimetry by Edith H Quimby, on equipment by R L Weiland, on health physics by K Z Morgan, and on the value of autoradiography by C P Leblond and J Gross, and Hahn's examination of the general factors governing the present and future employment of isotopes in therapy is particularly helpful The established forms of therapy are discussed separately, with sections on radiophosphorus, on radio-iodine for thyroid carcinoma and hyperthyroidism, and on colloidal radio-isotopes given by infiltration and intravenously No detailed consideration is given to the external use of phosphorus, intraperitoneal colloidal isotopes, intravesical cavity radiation, or the possibilities of intravenous colloids for lung embolisation and therapy One difficulty facing the compiler of any textbook on this subject at the present stage is that it tends to be either very general or very particular, without enough attention to the tentative and developing fields of work which cannot be clearly defined or assessed In some ways Dr Hahn has escaped this difficulty, although possibly his analysis of the general scope of radio-isotope treatment might have been more usefully based on body areas and on functions than on a list of the chemical elements Some chapters, notably that on the treatment of hyperthyroidism, also give a good account of the uncertain state of present practice and of future possibilities The discussion, in several sections, of purely diagnostic applications may seem inappropriate, but this is justified where treatment depends largely on such applications It is perhaps early to look for a comprehensive account of radioisotope therapy with broad perspectives, and Dr Hahn's book gives an excellent, if slightly disjointed, picture of the present state

Incontinence in Old People

John C Brocklehurst, M D, *major*, R A M C, *formerly*
Christine Hansen Research Fellow in the University of
Glasgow Edinburgh E & S Livingstone 1951
Pp 187 30*s*

The value of this monograph lies both in the light it throws on one of the more distressing disabilities of old age and also in its emphasis on a physiological approach and the need for research into predisposing and precipitating factors The subject is dealt with clearly and comprehensively in three separate sections, which are amply illustrated with diagrams and photographs

Part I consists in a critical review of previous reports The anatomy and physiology of the bladder and rectum, the mechanism of normal and abnormal micturition, and the causes of senile urinary incontinence are described in detail, and the effect of drugs on the bladder and rectum is discussed

Part II, dealing with the ætiology of incontinence in old people, describes a study of the bladder, rectum, and anal sphincter in senile incontinent patients By cystometry on a series of incontinent patients the author has confirmed the previous finding that the cause of urinary incontinence in old people is over activity of the bladder mechanism due to interplay of various factors He emphasises that of these factors impairment of the cortical inhibitory function is the most important Not everyone, however, would agree that a chronic urinary infection has little bearing on the disability, and most clinicians might maintain that the elimination of such an infection, if present, would contribute to the relief of the incontinence From a similar investigation of rectal function, by means of a rectometer, the author concludes that the rectum in senile incontinent patients is more than usually excitable

Part III concerns the management of incontinence in old people From the point of view of treatment these patients are divided into two groups—those who can coöperate, and those who cannot For the former group, the author rightly suggests that re education in inhibitory control and symptomatic treatment of local conditions is the proper mode of attack As to the latter group, he holds that the problem becomes one largely of efficient drainage, and he describes the use of a moulded bed in the management of incontinence Others might not agree that in the uncoöperative patient incontinence is entirely irremediable, and it might be argued that the stimulus to regain bladder control is removed by an appliance which not only tacitly encourages the patient in her incontinence but also largely immobilises her Only practical experience will show how far such an appliance should supersede careful nursing and mobilisation, which may still be preferable even for the mentally confused and uncoöperative

Recent Progress in Psychiatry

Editor C W J H Fleming, M R C S London J & A
Churchill 1950 Pp 711 Price 50*s*

Seven years have elapsed since this volume's forerunner was published It contains a wealth of material including eighty pages of references, variously grouped But though psychiatrists will value this book for reference, he would be a remarkable man who could sit down and read any of the articles offhand As a display of knowledge and energy the book is magnificent, but there is little evidence of selection in the feast of material so lavishly supplied The shorter articles, rather than the more erudite, will carry most conviction to the average psychiatrist

Lecture Notes on Emergency Diagnosis

Hanns L Baur, professor of internal medicine, University
of Munich Oxford Blackwell Scientific Publications
1951 Pp 68 6*s*

This little book is designed for the medical student and contains much valuable information presented from the physiological standpoint Diagnosis is approached by careful reasoning and not by a series of lists of causes and a feat of memory There is much that may appear almost unnecessarily simple but which will give the student a sound basis on which to build his clinical judgment There are in all seven chapters, dealing with such subjects as the facies, the skin, disorders of breathing, coma, fits, and the like There is no index as such, and the book is intended to be read through rather than used as a book of reference A few minor difficulties in translation do not prevent it being pleasantly readable

A Medical History of Persia and the Eastern Caliphate

From the earliest times until the year A.D 1932 Cyril
Elgood, M D, F R C P, late physician to H.B.M. Legation,
Teherân, Persia London Cambridge University Press.
1951 Pp 614 50*s*

To read Dr Elgood's preface is to form some idea of the difficulty of the task he has undertaken In the earliest period up to the Islamic conquest, the material is scanty and written in the ancient Persian tongue, which few can read The author, if he is here often compelled to substitute a sketch of the history of the Persian State for a history of its medicine, at least makes it interesting, as when he writes of the treatment of the captured Roman emperor, the aged Valerian, by the reigning monarch who, whenever he rode abroad, mounted by means of a foot placed on the neck of a Roman emperor But with the coming of the Arabs Dr Elgood is able to hold our attention by his intimate knowledge of Arabic medicine The final period, after the arrival of the East India Company in the reign of James I, makes easier reading for most of us It demonstrates again, and in another field, how great is the contribution of medicine in the spreading of Western civilisation

Dr Elgood writes well of his difficult subject, but since it is admittedly difficult one could wish that he had adopted the example of the history textbook, prefacing his chapters by something of a synopsis and introducing those tables of dates, of dynasties, and of the succession of eminent physicians, which might make it all a little easier to comprehend Dates repeatedly placed in an outstanding position, like maps (of which there are none), are a great help in following an intricate presentation of events.

internecine dispute on the function of a particular hospital without asking our people to return to an outmoded method of finance?

Though this brave, if misguided, enterprise at Kingston may well succeed, we should not overestimate its significance for though private money may be forthcoming for isolated endeavours of this sort, it will never again be found for a comprehensive hospital service. Beyond the neighbourhood of Kingston the effect can only be to make people glance uncertainly back at the years up to 1948. Yet this country is deeply—and, we believe, wisely—committed to the National Health Service. Those who recognise this should seek to remedy defects through the boards and committees within the service—and none can assert that here medical opinion has no outlet—or through the strong professional bodies outside the service. Any who encourage their neighbours to step back to 1948 are themselves out of step with the times.

Annotations

COTTON-WOOL

THE latest edition of the *Drug Tariff* (for April) includes for the first time a detailed specification for "hospital quality" cotton-wool. Hitherto the National Health Service has recognised only the *B.P.C.* standard, which is perhaps unnecessarily high for some surgical purposes, such as colostomy dressings, where no harm is done by airborne flecks of wool. The pharmacist must still supply a *B.P.C.* wool unless "hospital quality" is specifically ordered on the prescription, but doctors are asked by the Ministry to order this as often as they can partly to save the Service's money but also because of the scarcity of raw cotton suitable for making *B.P.C.* wool. The difference in price is appreciable—*B.P.C.* 8s. 5d., "hospital" 7s. 5d.—and the absorptive powers of the two are about the same. The main differences in the specifications are that the "hospital" wool need be only reasonably free from pieces of thread, whereas the *B.P.C.* insists on unqualified freedom; a little more fibre-dust and other foreign matter is allowed in the "hospital" specification; and the average staple fibre can be $^1/_4$ inch shorter in the "hospital" wool. The *B.P.C.* demands "appreciable resistance when pulled," whereas the specification for "hospital" quality does not mention resistance; this probably explains why patients who do their own dressings usually say the *B.P.C.* wool goes further and is less trouble to use. They also say that the wool interleaved with paper seems more economical than the more usual form in which the roll is apt to become an amorphous lump. It might be worth while to interleave both "hospital" and *B.P.C.* qualities, perhaps reducing their thickness at the same time. Otherwise a general change to a short fibre wool may add to the cost instead of saving money.

The reasons[1] for the rise in price are multiple and complex. When the pound was devalued in September, 1949, the price of raw cotton in England was bound to rise. But before devaluation had exerted its full effect, many countries began to lay in stocks of cotton for rearmament, because war had broken out in Korea. Then the Indian government banned the export of raw cotton, and Pakistan reduced its supplies to Britain. The British maker of *B.P.C.* cotton-wool, which is a mixture of the high and medium grades of Indian cotton, now found the higher grade unobtainable, the only alternative being Turkish cotton about equivalent to the Indian medium grade. Inferior cotton wool is made from low-grade cotton mixed with "linters" (cotton-waste), and the prices of raw cotton are controlled but that of cotton-waste is not—hence we are faced with the anomalous position that the price of inferior cotton-wools is rapidly approaching that of the better qualities. Similar difficulties are facing the manufacturers of lint, gauze, and bandages, who before the war used only American cotton, but now, owing to the shortage of dollars, must buy Egyptian yarns of unnecessarily high grade and corresponding high cost. There seems little hope of improvement in the cotton position for some time, but it is possible that rayon dressings[2] will help to ease the shortage.

This would have been a good time to erase for ever the unfortunate term "hospital quality," meaning "inferior quality." There was a time when hospitals were expected to make do with the cheapest sorts of dressings, whether wool, lint, gauze, or bandages. Obviously there is a place in hospital practice for two qualities of such materials, but that is no reason for calling only the worse of the two by their name. A more colourless terminology, such as "standard quality" for what is now hospital, and "super quality" for the present *B.P.C.*, would surely be preferable.

ALCOHOL AND THE MOTORIST

THE attitude of the peoples of different countries to drunken motorists seems to correspond roughly with their philosophy of life. In Scandinavia the attitude is keenly efficient, while in the sun-touched south it is one of live and let live. An international conference held last year[3] made it clear that laws against intoxication while driving vary from extreme severity to a laxity almost approaching indifference.

In Scandinavia the problem of alcohol and traffic is widely depicted on posters as a "dangerous crossing" between the car and the bottle, and legislation to discourage this transition is severe, well defined, and ruthlessly applied. On the other hand, in such countries as Italy, Spain, Portugal and the Argentine penalties are not heavy; in Spain there was until last year no legislation against this offence, and driving licences were withdrawn only in extreme cases. The various statutory measures are precautionary, punitive (deterrent or corrective) and educational. Precautionary measures consist mainly in care in the issue of driving licences. Of punitive measures the most usual is withdrawal of the driving licence: this step is taken even in Spain if the motorist drives "in an acute alcoholic state." In Belgium there is legal provision for withdrawing the right to drive (no system of driving licences has ever been in force) and impounding the vehicle; these punishments are said to be of greater deterrent value than fines or imprisonment. Most authorities impose fines for the first offence and imprisonment for the second or subsequent offences; but in Denmark, Norway, Finland, and Iceland imprisonment is the rule even for a first offence except under extenuating circumstances. In Finland a drunken driver can be imprisoned for 8 years if found guilty of homicide, and for 6 years if the accident results in bodily injury. The Italian law betrays a certain sympathy for the drunken driver, for "no person is liable who has committed a crime deprived of the power of comprehension and will due to intoxication derived from fortuity or inevitable accident." (Punishment is, however, augmented when intoxication is premeditated in order to commit a crime or create an *alibi, or if the* crime is committed in a state of "habitual drunkenness.") The value of educational and propagandist measures was generally acknowledged at the conference. In Sweden the Union of Temperance Drivers carried out a vigorous conditions, by means of venous occlusion plethysmography, found that intravenous injection caused pronounced vasodilatation in the skin of the extremities, and that intra arterial injection doubled the calf blood flow and increased the flow through the foot to a still greater extent Intra arterial injection after acute arterial embolism produced pronounced, vasodilatation, and increased the foot flow threefold in the sympathectomised limb , but intermittent claudication was not relieved in any of eight cases of occlusive arteritis DOUTHWAITE and FINNEGAN[5] found that priscol acted powerfully upon the smaller arteries and arterioles of the fingers and toes, and had a more lasting action than other vasodilators when given by mouth Unlike LYNN, they found that intermittent claudication was relieved , and in twelve out of twenty-four cases of occlusive disease night pain was abolished They suggested that the value of priscol was likely to be greatest in Raynaud's disease, but that it should also be tried in peripheral arteriosclerotic disorders They advised against its use in hypertension, since doses large enough to lower the blood-pressure produced alarming side effects , these occurred even with smaller doses which did not affect the pressure at all IGLAUER and his co-workers[6] reported that priscol did not affect cardiac output Lately GOODWIN and KAPLAN[7] have shown that in occlusive peripheral vascular disease oral administration of priscol reduced the calf toe temperature difference and shortened the circulation-rate in the lower limbs Numbness, coldness, and rest pain were much reduced or abolished , and of ten patients with claudication nine claimed that its severity lessened After the drug was withdrawn, however, the findings were little different from those before administration was started Side-effects were slight, and the drug was administered to patients with anginal pain and ischæmic heart disease without untoward incident ZURROW and his associates[8] noted that priscol increased gastric acidity

[2] Fairburn, J W, Whittet T D *Ibid* p. 161

[3] Proceedings of the First International Conference on Alcohol and Traffic 1950 Stockholm Kugelbergs Boktryckeri. 1951 Pp 336 15 Sw Kr

The evidence thus suggests that priscol is an effective peripheral vasodilator, acting mainly on the skin vessels There can be no doubt that it is a powerful sympatholytic agent, capable of acting directly on the denervated vessel wall It is unlikely to prove of any value in the treatment of hypertension , but, especially owing to the absence of serious side effects, it should find a place in the treatment of peripheral vascular disorders It should, however, not be given intravenously to patients with recent coronary occlusion or myocardial infarction In acute arterial occlusion the intra arterial injection of priscol is probably not only as effective as paravertebral procaine block, but also safer and more certain in its action Intravenous injection of the drug, by indicating the capacity of vessels to dilate, may be useful when sympathectomy is being considered Of perhaps greater importance is the ability of priscol given by mouth to produce peripheral vasodilatation without serious side effects Probably all patients with vasospastic disorders should have such treatment before sympathectomy is decided on , and the drug may also be given after operation to supplement the effects of surgery In occlusive peripheral arteritis the value of priscol is less well established , but despite the discouraging results quoted by LYNN it seems to be of definite, if limited, value when given by mouth It offers ambulant patients a reasonable chance of some improvement in peripheral circulation, without sympathectomy Long term studies may show that its action is more ephemeral than is at present hoped , but certainly this drug presents new possibilities in a group of disorders whose treatment is commonly almost as disheartening to the physician as to the patient

The Wrong Way

THE controversy that has raged for months over the proposed conversion of Kingston Victoria Hospital from a general-practitioner hospital to a gynæcological unit has reached an abrupt climax with the closure of the hospital and the announcement by the displaced doctors and others of a scheme to open a voluntary hospital in the neighbourhood Alternative accommodation is being provided by the regional hospital board, and some thirty practitioners have already signified their willingness to work there , but others, holding that the accommodation is inadequate, will have nothing to do with this arrangement Instead they plan, as we note in our news columns this week, to collect a fund of some £50,000 to purchase, adapt, and equip a house as a hospital with 15–20 beds, and to cover the costs for the first two years

The sponsors of this enterprise must have weighed the difficulties Structurally the proposed hospital can offer little more than countless other large houses already adapted as nursing-homes , and, like most small nursing-homes, it is likely to prove too small to run efficiently and yet with proper economy in nursing and other staff Furthermore, for such a small unit to have its own radiological and pathological departments would be an extravagance , yet without these departments it might have to depend on the good will of institutions in the National Health Service Unlike most of us the sponsors may count money the least of their worries for the appeal will draw together those of us—and they are many—who always want to back the little man against the big, as well as some of those who hold that the general practitioner has been roughly handled by the regional hospital boards , those who resent the breach of a long tradition at the hospital , and, of course, those who would not be disappointed to see the National Health Service fail General practitioners throughout the country have ground for resenting their gradual displacement from hospitals which they once staffed , but is this reason enough for asking the public to return to the discarded method of charitable support ? Does not the Kingston appeal indeed show up some of the weaknesses of the old method ? This appeal is being placed before the public in an area where the need is less than in other parts of the country A new hospital of this type might better be started in an area where the general practitioner has no contact with hospitals, no hospital beds of his own, no access to diagnostic departments, and little say on advisory committees But in Kingston the practitioner can have all of these, if he wishes And in any event should not the profession be able to settle this for tasks of this kind, under magnifications up to ×200, that Barer and Saunders Singer[2] have devised their new low-power microdissector. This works on pantograph principles, but the family failing, an incurable backlash, has been overcome by spring loading, and accurate counter-weighting ensures that the instrument will "stay put" when the operator takes his hands from the controls. In the present model the dissecting instrument will follow every movement of the operating handle, but at a reduction of 4 : 1, so the average shaky hand will not wobble the tip of the tool more than about 25 μ.

THE ADOLESCENT DELINQUENT BOY

THE juvenile delinquent is much in the news, partly because of the disquieting rise during the past ten years in the number of young persons found guilty of indictable offences, and partly because new methods of handling those offenders arouse heated controversy. The publication by the British Medical Association of a booklet[3] on the subject is therefore timely; it embodies the report of a joint committee of the B.M.A. and the Magistrates' Association with three coöpted members, under the chairmanship of Dr Doris Odlum, and is intended to complement a report on the unstable delinquent girl[4] published in 1946.

The new publication deals with boys between the ages of 13 and 17 who are delinquents, truants, or beyond control. It outlines various factors affecting adolescent delinquents: their home circumstances and the character of their parents, including the problems of broken homes, illegitimacy and adoption; intelligence and education (the latter may suffer severely in the truant); employment difficulties; use of friends and leisure; deficient money sense; lack of religious values; level of physical health; and the effects of the cinema. The powers of courts in dealing with the juvenile offender are summarised, and the last section contains the committee's recommendations for dealing with the problems discussed. Of these recommendations perhaps the most noteworthy are: early detection of ill treatment or neglect of the child, and his removal from harm as soon as possible under the provisions of the Children's Act, 1948; greater provision of educational facilities for the educationally subnormal child (last March the Minister of Education stated that in England and Wales there are known to be 28,000 requiring such provision, but only 15,000 can be dealt with); greater coöperation between the leaders of youth organisations and parents, and the encouragement of boys to join clubs while still at school; special placement in industry of more backward boys; measures to educate future parents both by pre marital advice and by social and psychiatric services to deal with marital disharmony; increasing the police force in order to deter the potential delinquent; special methods for dealing with the persistent absconder; and early recognition of the delinquent who is unlikely to respond to any form of treatment.

While undeniably the causes of delinquency are many and various, it is regrettable that the report, though usefully summarising a wide range of opinions, gives an over-all impression of superficiality. It never really faces up to the enigma it propounds in its opening paragraph: "a very great number of boys who have the same characteristics or the same environment as those described here . . . do not become delinquents." This problem of "differential response" as Reckless[5] terms it, or "susceptibility" to use the phrase of Carr Saunders et al.,[6] was comprehensively discussed by Bowlby,[7] who quotes the findings of Burt, Aichorn, Healy and Bronner, and Stott. Bowlby's own work[8,9] led him to conclude that two factors are especially significant in the history of the persistent delinquent: (1) prolonged separation of the child from its mother or mother substitute during the first five years of life; and (2) the child being more or less unwanted by parents whose main attitude towards it is hostile, critical, and punitive.

That the attitude of society towards the delinquent and his often irresponsible parents is also mainly hostile, critical, and punitive remains a large ingredient in this chronic social problem. Dissemination of information, as in the present report, is likely to help by arousing public interest and sympathy for the delinquent; but, apart from deeper understanding of the underlying reasons for his having "fallen among thieves," we are apt, like the Priest and the Levite, to view his predicament impersonally from the other side of the road.

A DANISH ANATOMIST

THE eponyms which haunted our anatomy years linger on when nothing remains of that prodigious feat of memory but astonishment that we ever achieved it. Yet though the mature practitioner may brighten momentarily at the words "Stensen's duct" he is apt to look blank again if asked who Stensen was. In the introduction to a new Danish edition of *A Dissertation on the Anatomy of the Brain*,[10] Prof Edv Gotfredsen describes Nicolaus Steno, or Niels Steensen, as one of the outstanding scholars of the 17th century, equally well known as anatomist, geologist, and Catholic theologian. He was born at Copenhagen in 1638; and Thomas Bartholin, another famous Danish anatomist, discoverer of the lymphatic vessels, was among his teachers. Steensen's contemporaries held a number of beliefs based on opinion rather than investigation. Thus Thomas Wharton, who, in 1656, gave his name to another salivary duct, held that tears originated in the brain, and that milk came from the chyle, not the blood. Steensen was the first to assert that all glandular secretions, including milk, are derived from the blood. He discovered not only the parotid duct which bears his name, but the minute ducts of the lacrimal gland; moreover he described the lacrimal apparatus fully, and recognised that tears are simply a liquid for the irrigation of the eye. He also demonstrated the existence of the buccal glands and of the cerumen secreting glands of the ear. His work on the structure of muscle ran directly counter to opinion at the time. Galen's view that the tendons were principally responsible for movement held the field, and the fleshy part of the muscle was conceived as mere packing material through which ran contractile fibrils from the tendons. Steensen demonstrated that muscle tissue was made up of contractile fibrils, and that the tendons were merely anchoring cords; and he also showed—nearly a hundred years before von Haller—that muscle contracts as a result of a direct stimulus. He described the muscles of the tongue and the œsophagus, and the levatores costarum; but most remarkable of all, at a time when even Harvey regarded the heart as the altar of the body where the blood was made liquid anew and impregnated with vital spirits, Steensen was able to state, as a result of his careful examination, that the heart was made of nothing else but muscle. He observed the ovarian follicles before de Graaf published his account of them, and the lymphatic plaques in the small intestine in the same year as Peyer; and he published the first account of campaign in 1949, with mass meetings, lectures, films, and other methods, which resulted in a reduction in injuries and deaths and in the number of intoxicated drivers. A mutual insurance company for non-drinkers, established in 1933, now has a claim rate 37.08% lower than the average of other companies.

A British representative held that, since alcohol is a narcotic interfering with judgment and self-criticism, even when taken as "half a glass of pale ale," there is only one safe rule: not to drink for a given number of hours before driving. Swedish representatives contended that only with an alcohol blood level above 0.02–0.04% will driving efficiency be impaired. In Scandinavia, Czechoslovakia, and South Africa blood tests are compulsory for determining intoxication. Swedish pharmacologists have found that ordinary clinical examination gives uniformly positive findings only with a high blood-alcohol level; below 0.15–0.2% some people "pass" a clinical examination even though far from sober. Road tests showed that the threshold for impairment of performance was at a blood alcohol level of 0.035–0.04%. In most countries guilt depends, not on intoxication alone, but on the influence of this condition on ability to drive safely. Norwegian law, however, does not consider this ability at all. A blood level of 0.05% is regarded as proof that the driver is under the influence of liquor, and imprisonment is then almost automatic. In Sweden there is usually no punishment unless the concentration exceeds 0.08%; with a concentration of 0.08–0.15% the culprit is usually fined, but a concentration of over 0.15% almost always involves imprisonment.

SAFER CHILDBIRTH IN NEWCASTLE

"How to make the best of an old building" would make a good subject for an Ideal Hospital Exhibition in these lean years. The Princess Mary Maternity Hospital at Newcastle upon Tyne is the teaching centre for obstetrics of the University of Durham. At the outbreak of war it was transferred from the original building beside the Tyne to an orphanage on the outskirts of the city, an ugly, ill-planned, two-storeyed Victorian building, with winding stone corridors, awkward stairs, and very few small rooms. The wards are large, and the sluices and kitchens inconveniently placed at varying distances along the corridors. There are no staff rooms on the wards, and nowhere to receive relatives or friends. This awkward place had to serve a parish of 3000 square miles in Northumberland and Durham, with a population of over 2 million. Well over 2000 children are born there yearly. Yet, despite the drawbacks of the building, the medical and nursing team have been able to establish and maintain a high and rising standard of pædiatric practice, accounts of which are now being presented in a series of pædiatric reports introduced by Prof. E. Farquhar Murray as chairman of the medical staff and Sir James Spence as pædiatric physician. Those for 1946 and 1947 have so far appeared; they have been compiled by Dr. Donald Court from the observations recorded by the pædiatric registrar, who had the day-to-day care of all the infants born, and they supplement, by lucid narrative and attractive diagrams, the detailed figures given in the annual medical reports. Indeed, both in scope and in production, they are a model for those who seek to interest other people in their work.

In 1946, besides the registrar, the medical staff included 2 house-surgeons, a resident obstetric officer, a non-resident first assistant, 3 visiting obstetricians, and the professor of obstetrics of Durham University; on the nursing side, besides the matron, assistant matron, and sister tutor, there were 15 midwives, 20 State-registered nurses working for the C.M.B., and 21 untrained girls taking the eighteen months' midwifery course. Medical students conducted 1080 of the 2352 births, pupil midwives 734, and the medical staff 538. Of the 2189 children born living, 2088 went home alive and well, and 85% of them were breast-fed when they left hospital. Breast-feeding is taught assiduously, and even those babies who had to be fed artificially usually received the feed as a complement after the breast. Only 1.4% of mature and 24% of premature infants were entirely artificially fed, and in 1947 (when confinements numbered 2369) the figure for premature infants had fallen to 21%. Infections were taken very seriously, for in the first six months of 1944 infections had caused the death of 47 infants. All unnecessary routine nursing procedures—such as test-weighing—were therefore restricted; the babies were placed in cots beside their mothers' beds and not transferred to the nursery unless they were exceptionally noisy; they were even changed in their cots. The pædiatrician watched the children and started chemotherapy as soon as any infection developed. The result was that in the 30 months from July, 1944, to December, 1946, only 67 babies were seriously infected, 20 died—a fall in mortality from 50 to 4 per 1000 live births. In 1946 itself only 6 children died of infection, and in 1947 only 3—a further reduction in the mortality from this cause to 1.4 per 1000 live births.

The main causes of stillbirth were maternal disease (including toxæmia of pregnancy), birth injury, and fœtal malformations; in 1946 the rate was 69 per 1000 births. The neonatal death-rate was 46 per 1000 live births, and prematurity was the greatest predisposing cause. In 1947 the stillbirth rate was 63 and the neonatal death-rate 26. The annual medical reports for 1946 and 1947—prepared by Mr. Hugh Arthur and Mr. E. L. Nicholson, who joined the hospital staff at the end of 1946—show that part of this improvement was due to a falling mortality from breech delivery and forceps delivery, and in persistent occipitoposterior positions. These figures, however, relate to a hospital in which the "emergencies" are high, accounting in recent years for a quarter of the total admissions. Only 281, or 12%, of the 1947 births were premature, but this small group included over a third of the fœtal and nearly half the early neonatal deaths. Only half the infants weighing less than 3½ lb. survived, and the report comments that had some incubators and more nurses been available probably three-quarters of them could have been saved. Prevention of premature labour would be even more desirable; and this is a subject, as Dr. Court points out, for much closer study.

A LOW-POWER MICROMANIPULATOR

In the past, laboratory operations under the low-power microscope, such as the dissection of small embryos or the selection of minute crystals, have been done freehand, on the principle of What the Eye Can See the Hand Can Follow. With one of the high-power micromanipulators previously discussed in these columns,[1] or the Singer model which is British made, it is possible to pick out a single bacterium or remove the nucleus from a tissue cell; these instruments are intended for manipulating objects between (say) 0.5 μ and 50 μ in diameter, the main emphasis of their design being on precision rather than mobility or speed. The freehand technique is probably as convenient as any for dealing with objects down to diameters of about 0.5 mm.; the difficulties arise between this size and 50 μ, where a high-power manipulator is essential. Anyone who attempts the more tedious manœuvres of this order of magnitude, like sorting diatoms, pollen grains, or mould spores, without some mechanical aid, soon begins to develop an intention tremor, usually of about 0.1 mm. in amplitude; and this tends to be at its worst at critical moments—nothing tires the hand more quickly than movements of a few microns on which the whole experiment hangs. It is

HOSPITAL SCHOOLS

J HYWEL WILLIAMS

HEADMASTER, WELBURN HALL SPECIAL SCHOOL, KIRBYMOORSIDE, YORKS; FORMERLY OF CANADIAN RED CROSS MEMORIAL HOSPITAL SPECIAL SCHOOL,[*] TAPLOW, BUCKS

PROVISIONS for the education of chronically sick children were conceived in the minds of the liberal reformers of the latter part of the 19th century. The establishment of day and residential schools for cripples who were no longer receiving active medical treatment was followed by the introduction of schooling in a number of special hospitals treating chronic conditions in children of school age. Since that time, about a hundred hospital special schools have been established.

There are now several types of schools for physically handicapped children. The hospital school differs from most of the others in that it offers a supplementary rather than a primary service, and school work is necessarily subordinated to the need of the children for active medical treatment. These differences decide in some measure the function of the school, and certainly have considerable influence on the teaching techniques which can be used effectively in it.

The policy followed in any particular school must be directed partly by the function of the hospital it serves. Where treatment may last some years, the teacher faces problems quite different from those met by a teacher whose pupils will be returning to their ordinary schools in a few months. The first may well be influenced by the fact that the patient will finally need sheltered employment, while her colleague knows that her patient must be able to take his place with his contemporaries when he goes back to his ordinary school. Any analysis of the function of hospital schools must therefore be limited to a few general principles, and these will be modified by local conditions affecting individual schools.

RESTORING CONFIDENCE

The child admitted to school in a hospital is generally educationally backward, his standard of performance is not compatible with his intelligence quotient. He often has a history of irregular attendance or even long absences from school. Even where attendance has been regular until his current illness there will be a break between his last attendance at school and his admission to hospital. It must be remembered, too, that the child admitted to hospital is not immediately admitted to the hospital school. The time lag here depends, of course, on his medical condition and the amount of active treatment he receives. The break may often extend over several terms. The child will then have lost much of what he had previously learned, and with it his confidence in his ability to learn. Because he is ill, he will be emotionally disturbed to an extent depending partly on his medical condition and partly on his own natural emotional make up.

The teacher has the immediate task of restoring his confidence, by helping him to recover his original standards of performance. Some subjects of the curriculum, such as arithmetic, lend themselves to measurable standards more easily than others, and it is usually through these basic subjects that the teacher makes her first approach. Confidence is restored by achievement, and the teacher should be able to grade the work so that the child experiences this sense of achievement to the full.

It often happens that the child has been educationally retarded for a long period before his admission to hospital, and has lost hope of ever keeping up in formal subjects. But he clutches firmly to his one achievement, whether it be his ability with a paint brush, with craft tools, or with a musical instrument. Usually his strength lies in subjects that do not impose the arbitrary standards of number and reading—subjects where a result need be neither "right nor wrong," but just "a good attempt", and where there is scope for interpretation rather than accuracy. Such a child can be led along the line of his interests, and through them can make his contribution to his contemporary group, besides gaining the satisfaction that comes from achievement.

Brian was such a case. He was admitted to the hospital school at the age of 12, having attended school for just a year since arriving at school age. He had spent much of his time in hospital, and more of it at home, being nursed by his grandmother. When he was admitted to hospital school he was illiterate and could not do simple sums. His physical condition (he was a case of Still's disease) restricted movement. But despite all his handicaps, he had one skill to his credit: he wrote with a neat hand. From this he gained considerable pleasure, and he spent much of his time copying out what were to him, at first, meaningless words.

He was then asked to write a story. At first reluctant, he ultimately agreed to make the attempt, on condition that the teacher corrected the spelling errors in the original and allowed him to copy out the story in his book. He will never reach any high standard of authorship but he is beginning to write coherently and now, after 12 months' interrupted hospital education, he is writing and illustrating his own book. He can also read and is engrossed in his current interest—what he calls symbolic art. "You don't paint a thing how it looks sir you paint it as you think it ought to look," was the comment he offered when I asked him what he was trying to do.

The children admitted to a hospital ward come from all types of school: there are pupils from grammar schools, and those who are educationally subnormal, children from Home Office establishments, and children from preparatory schools, pupils working for School Certificate, and those who are struggling with the beginnings of number and reading. The work is further complicated in nearly half our hospital schools by the fact that the children are not distributed according to age. The approach of the teacher must, therefore, be to the individual, wide age ranges and differing standards demand individual teaching, particularly in the basic subjects.

But the child is also a member of the ward community and should be encouraged to make his contribution to its life. The teacher must be able to design group activities which will give scope to the interests and abilities of her pupils, and lead to pride in personal achievement and in the satisfaction of making a useful contribution to the group. Nearly three quarters of the children attending hospital schools return to their homes, and to ordinary schools. There they are expected to take their place in a competitive community, and the hospital teacher must see that educationally, at least, they will be able to do so.

THE WORKING BACKGROUND

The pioneers in the education of the sick child were moved by pity, they were disturbed by the conditions under which crippled children were allowed to exist. Today we are asked to regard such children as perfectly normal and to treat them as such. There is something of truth in both these attitudes, but they both carry attendant risks. Sentimentality towards the sick child can create an emotional disturbance which might not otherwise have developed, yet if we treat the patient as a perfectly normal child suffering from a local condition we may well fail to recognise a disturbance which already exists.

The doctor can achieve some of his results without the willing cooperation of his patient, but the teacher can achieve nothing unless the child is fully cooperative. She cannot impose the sanctions of the normal school: there can be no detention after school hours, no corporal

"Fallot's tetrad" nearly two hundred years before Fallot was born.

The new Danish edition of his dissertation on the brain contains not only a facsimile of the original treatise, as it was delivered to the French Assembly in M. Thevenot's house in 1665, but also the English translation, made by Dr. G. Douglas in 1733, which was incorporated in James Winslow's "Anatomical Exposition of the Structure of the Human Body." It is a beautifully scientific work, confessing ignorance, refuting unfounded assertions, proposing investigations, suggesting experiments. Especially he pressed the need for careful dissection:

> "As the Brain is a Machine, we must not flatter our selves that we can discover the contrivance of it by any other means than are made use of for knowing other Machines and we have no way left but to take it to pieces, and to consider what every part is capable of in a separated and an united state."
>
> And again: "This method of Dissection makes indeed but a very small Shaw, and a Man cannot well display his Learning at the same time that he acknowledges his Ignorance: but as for my own part I much rather choose to own what I do not know, than to impose upon my Hearers, ancient Opinions, which will some time or other be demonstrated to be false."

Steensen's achievements in geology were hardly less remarkable than his contributions to anatomy; and indeed geologists regard him as the founder of their science. His remarkable mind, however, had still another field to explore. In 1667 he was converted from the Lutheran faith, in which he had grown up, to Roman Catholicism; and in 1675 he gave up all his scientific studies and entered the priesthood. He quickly rose to a bishopric, and became apostolic legate for Northern Germany and Scandinavia; but his natural austerity led him to forsake these honours, and he died a plain priest, in great poverty. He is buried at Florence in San Lorenzo, the church of the Medici.

CONTROL OF TINEA CAPITIS

THE rational treatment of ringworm of the scalp depends on identifying the responsible fungus; its dissemination can be prevented only if the local human and animal nidi of infection are found and eliminated. *Microsporon audouini* is the commonest infecting organism, accounting for most school and institutional epidemics. *M. canis*, in which the kitten and not the puppy is usually the host, is a less common cause; it gives rise to sporadic cases in which infection becomes attenuated by child-to-child transmission and eventually dies out, unless enhanced by infection of an animal host, after 4–6 human transfers in series. In some country communities trichophyton infections, usually acquired from calves and occasionally from horses, are a further cause of tinea capitis. Of 1004 cases examined in Northern Ireland by Beare and Cheeseman[1] 957 were small-spore infections; in 806 the organism was *M. audouini*, and in 85 *M. canis*, while in 66 the organism was undetermined. There were 43 trichophyton infections, 1 of favus, and 3 kerions. *M. audouini* is essentially the fungus of epidemic ringworm, so these figures from a limited district may be misleading. Walker,[2] in a three-year survey of the dermatophytes in Great Britain, examined material from 2015 cases of tinea capitis and isolated *M. audouini* in 1427, *M. canis* in 505, *M. gypseum* in 2, and various trichophyta in 81.

In identifying infections with small spores Wood's light is indispensable; in some cases of tinea capitis, particularly of long standing, naked-eye examination may show little or no abnormality, whereas examination with Wood's light reveals extensive areas of infection. When spontaneous cure is taking place the fluorescence becomes less brilliant. The nature of a miscrosporon infection is not readily determined without culture, but Beare and Cheeseman describe six points of differentiation which have enabled them to make a correct forecast of the culture findings in 97% of cases. These six points are: (1) the tendency of *M. audouini* to affect specific areas of a city, and of *M. canis* infection to arise sporadically; (2) the tendency of *M. canis* to cause more severe reactions than *M. audouini* (though sometimes there may be little or no reaction); (3) *M. canis* infections when examined under Wood's light lose their brilliance and after a few weeks appear dull green, whereas *M. audouini* fluorescence remains brilliant for some months; (4) visible changes in the lesions are more rapid with *M. canis* than with *M. audouini*; (5) a history of skin disease in a kitten in the house is far more common with *M. canis* than with *M. audouini* infections; and (6) associated tinea corporis is much more common with *M. canis* scalp infections than with *M. audouini* infections. Early identification of the fungus is important because *M. audouini* infections usually call for X-ray epilation, whereas *M. canis* can often be dealt with successfully by local applications.

X-ray expilation by the Kienbock-Adamson technique is still the best method of dealing with *M. audouini*, persisting *M. canis*, and *Trichyphyton sulphureum* infections; for children between 1 and 3 years of age this may have to be carried out under general anæsthesia. In infants under 1 year of age spontaneous cure is common, no matter what the organism, so that local application of fungicides may suffice. Local epilation is inadvisable because of the risk of subsequent infection of non-epilated areas, and because the resulting appearance is no better than when total epilation is carried out. Beare and Cheeseman found that salicylanilide in carbowax was ineffective, failure resulting in 7 out of 13 patients treated, and contact dermatitis in 3; in 1 patient severe folliculitis developed and led to gross scarring. Among 23 patients treated with salicylanilide in pentaglycol there were 14 failures. Manual epilation is a necessary accompaniment of local fungicidal applications, and the whole process is not only tedious but depends for success largely on the intelligent cooperation of parents. Nevertheless, Barlow and his associates[3] reported eventual cure in 64.8% of 261 cases of *M. audouini* infection treated with local applications, in an average time of 10 weeks. In their hands cuprammonium hydroxide in carbowax gave the best results (39 cures and 3 failures).

When local fungicidal applications fail it is because of their inability to penetrate into the hair shafts, their influence being confined to the epidermis and the follicles. In these circumstances their only virtue is in lessening the spread of infection on the scalp and to other children, until folliculitis and scarring, or natural spontaneous shedding of affected hairs, takes place: meanwhile absence from school is prolonged and the sense of uncertainty maintained. Fungicides are much more likely to succeed in *M. canis* than in *M. audouini* infections, probably because in the former they set up a folliculitis more easily and it is this inflammatory reaction and subsequent shedding of the affected hairs that leads to disinfection. For trichophyton infections other than *T. sulphureum* Beare and Cheeseman recommend boric starch poultices, manual epilation, and Whitfield's ointment; and they emphasise the importance of strenuous efforts to eliminate or at least reduce the cattle ringworm at present prevalent in some parts of the country, in an attempt to prevent these human infections.

SIR THOMAS WATTS, M.D., a former M.P. for the Withington division of Manchester, died at Southport on June 3, at the age of 82. For many years he was in practice at Hyde, Cheshire.

xcept those which do not come under the definition of rugs for National Health Service purposes The committee also listed the proprietary preparations which ught be prescribed under the health service

HEALTH CENTRES

A committee of the council has set out a plan for the ong term development of health centres, and has uggested ways of obtaining immediately some of the dvantages that health centres are intended to provide he committee proposes that all centres should provide eneral medical and some local health authority services, nd that some centres should provide dental services or more than one area, pharmaceutical services would lso be provided where necessary The centres should erve 15,000–20,000 people living within half a mile of the entre Because of the common fear of infection, tuberculosis clinics should not be held at health centres nless there are separate entrances and waiting rooms t is suggested that accommodation should be provided for 4–8 doctors, who should be encouraged to work in financial partnership Doctors would pay for the use of the premises, but dentists who receive a fixed salary from the executive council should not be required to do so Centres are regarded as suitable for the instruction of trainee assistants and medical students, but the committee is not in favour of encouraging permanent assistantships

ADVISORY COMMITTEES

Medical —This committee has been particularly concerned with economy in prescribing In conjunction with the standing nursing advisory committee it reviewed methods of controlling infection in hospitals and ways of improving children's hospitals Following a report by the World Health Organisation, the committee advised the Minister that prohibiting the use of heroin in the United Kingdom would be justified if international agreement were reached to prohibit the sale and manufacture of heroin throughout the world, but that heroin addiction was not a serious problem in this country The committee also considered the use of 'Cortisone the treatment of cosmetic disabilities in the National Health Service and certain detailed points in the economical use of drugs and dressings in hospitals

Dental —This committee has been concerned with problems of coöperation between authorities providing dental services, the employment of dental hygienists and the use of certain dental materials and drugs in the general dental service

Pharmaceutical —The committee has reviewed the questions of pharmaceutical man power pharmaceutical manufacture and research in hospitals, standardisation of accommodation and equipment, and the provision of a central syringe sterilisation service

Nursing —This committee has reported on methods of obtaining and collating information regarding approved nursing techniques methods of disseminating this information to hospitals and nurses and the techniques to be recommended In conjunction with the medical advisory committee the committee advised the Minister on cross infection in hospitals and, in conjunction with the tuberculosis advisory committee considered the precautions necessary to safeguard nurses from tuberculosis

Maternity —This committee continued to study the place of the maternity unit in the hospital service and decided that special attention should be given to the care of premature infants and to sick and injured babies throughout the country

Mental health —The standing committee on mental health recommended to the Minister methods of reducing the shortage of nurses in mental hospitals and mental deficiency institutions

Cancer and radiotherapy —The committee again considered the question of cancer publicity and revised a previous recommendation to remove the implication that local health authorities should omit any reference to cancer in their general health propaganda The revised recommendation reads It is undesirable at the present time for any cancer publicity to be carried out by the Minister directly to the general public " The council later expressed the view that no publicity should be carried out by any central Government organisation directly to the general public

CHARLES HASTINGS MEMORIAL FESTIVAL

MEMBERS of the medical profession assembled in Worcester on Wednesday, May 30 in brilliant sunshine, to commemorate the founder of the British Medical Association, Sir Charles Hastings Doctors in academic robes, entering the Cathedral by the west door from the terrace overlooking the river Severn, took part in the special service, conducted by the Dean, the Very Reverend W E Beck, during which Sir Henry Cohen, president of the association, laid a wreath by the Hastings memorial window

In his address the Bishop of Worcester, the Right Reverend W Wilson Cash spoke of the part that religion had played in the life of Hastings He grew up in an age of great reformers and so was never satisfied with things as he found them He had to improve and perfect All his actions were governed by his faith in God, while in his many activities he proved himself a man of courage, devoted to duty The Bishop referred to the importance of voluntary service in our national life, and said that long before the phrase " Welfare State " was coined, the medical profession, under the leadership of men such as Hastings, was introducing it on this voluntary basis

At a luncheon, under the chairmanship of Dr. W D Steel, in the beautiful banqueting-room of the Guildhall, Admiral Sir William Tennant, Lord-Lieutenant of the county and city of Worcester, proposed the toast of the British Medical Association, and Dr J A Brown, chairman of the Representative Body, replied Dr E A Gregg, chairman of council, proposed the health of the guests, and the mayor of Worcester, Alderman W H Norton, replied to the toast

The Charles Hastings memorial lecture was delivered by Dr W H McMenemey, who said that a keen sense of responsibility may have developed in Hastings from the time when his father met with an accident and was rendered incapable of managing his affairs, Hastings was then only twelve years old In his career as house surgeon at the Worcester Royal Infirmary he showed his organising ability, while at Edinburgh his powers of leadership became evident early on when he became president of the Royal Medical Society On his return to Worcester as physician to the infirmary, in 1818, he was elected president of the Worcestershire Medical Society—a body which may have been instituted by Hastings during his temporary sojourn in Worcestershire for reasons of health in 1816 A medical society had, however, existed in Worcester since 1799, the year when Dr A P Wilson Philip left Winchester to settle in Worcester Wilson Philip made a considerable impression on young Hastings and influenced him both in his experimental work, for which he seems to have had a real flair, and in his relationships with the governors of the infirmary The Worcestershire Medical Society continued in existence until Hastings became preoccupied with the more important Provincial Association Nevertheless, the local society was important in its day and petitioned both Houses of Parliament prior to Henry Warburton's second and successful attempt to regulate the practice of anatomy

If the stage was set for the establishment of a medical association in 1832 the success of the Worcester enterprise is attributable, said Dr McMenemey, to the personality, the enthusiasm, and the industry of Hastings, to his ability to persuade men to work together, and to his far sightedness in deciding to publish annual transactions and later a journal, both of which helped to weld the members together Moreover, his ideals were cast high and made a universal appeal " We take our Pole Star to be the alleviation of human suffering," Hastings once said The success of the association was remarkable Its annual meeting was christened the Parliament of the profession by the *Morning Herald* in 1838, and in 1851 punishment, no cancelled half day holidays, even the traditional "impot" is banned by the conditions of ward routine. Moreover, there is no single authority on the ward. The doctor, the sister and the teacher are all authorities, while even ward maids not uncommonly weigh in with their own interpretation of discipline.

The teacher needs, therefore, to tap all sources of information that will help her to obtain a comprehensive picture of the child. She should be told about the limitations imposed by the child's physical condition, she should consult the almoner on his social background, and the sister on his out of school activities and interests. The child's ordinary school should be asked about previous standards of work. Above all, the teacher must appreciate that on first admission to hospital, the child is emotionally disturbed. He has left his home and his normal associations and has entered a world which, in the first instance at least, can hold nothing but fear for him.

It might be true to say that the teacher is the first ordinary contact that the child makes in hospital. Certainly, he has met an occasional nurse at a school medical inspection, and he will have had some experience of doctors. But the teacher is an essential and accepted part of his normal everyday life, she brings into the ward something of the world outside the hospital, something of his old school, his friends, and a routine he can understand. She thus begins with advantages which can be used to help him to make happy relationships with his new friends in the ward.

Because the teacher is interested primarily in children, rather than in medicine or nursing, she should be able to detect causes of disruption or unhappiness in the ward. She should be able to suggest out of school activities, and suitable literature for the ward library. She has a contribution to make to the child's happiness while he is a patient, by introducing a diversity of interests she can lead him away from thoughts of illness and thus prevent those unhappy states of mind which are common to chronic patients of all ages.

The story has been told of the sick child who said he was glad they had introduced a school in his hospital, because "we now have something we can have a holiday from." This might be read as an indictment of the school, but I prefer to see it as the child's desire for the normal life of school and holidays, work and play and all the factors which contributed to the life which he has, temporarily at least, left behind him. The ward routine of washings and bedpans and treatment must in time pall on the dullest mind and the least inspired personality. Often the child may be ill yet not feel ill, and anything which destroys the frustration created by months in bed must have some value. At least the child can have a holiday from school: there is no holiday from the ward until he goes home.

The growing cooperation of doctors and nurses has done much to ease the work of the hospital schoolteacher during recent years. This surely, is a recognition of the fact that the child's social life in hospital is not without importance.[1] It is an attitude which acknowledges too, that a temporary physical illness should not result in a permanent educational deficiency.

---

[1] Maclennan, B. W. *Lancet*, 1949, ii, 209.

"… it was not possible under the terms of the Act to institute any system whereby a patient pays according to his means and thus to have a stake in treatment commensurate with his income. … The impetus to recovery, which in neurosis is difficult to maintain with some patients even under ideal medical conditions, was under these circumstances sometimes hopelessly damaged. In my view the offer of free treatment to neurotic patients by the National Health Service needs review, it is of doubtful benefit to all and a tragic disservice to some."—Dr. T. F. Main, medical director of the Cassel Hospital for Functional Nervous Disorders, in his report for 1948–50.

CENTRAL HEALTH SERVICES COUNCIL

During 1950 the National Health Service was settling down, and the report for that year by the Central Health Services Council[1] reflects the decrease in the number of major problems since its first report[2] was written.

TUBERCULOSIS

The standing tuberculosis advisory committee suggested schemes to provide more beds for tuberculous patients, and for recruiting more nurses, and action has already been taken on many of these recommendations. The committee also advised the Minister that hostels, under medical supervision, should be provided for chronic infectious patients who are able to get about, and that night sanatoria should be established for patients who are likely to recover and who are able to work. Sheltered employment for disabled tuberculous persons, on the lines of the 'Remploy' scheme of the Ministry of Labour and National Service, is advocated, in addition to the village settlements which already serve this purpose. Other recommendations include the establishment of clinics for treating rarer types of tuberculosis, and special centres for children suffering from, or susceptible to, tuberculosis. In accepting the committee's report the council drew attention to the importance of the general practitioner in any comprehensive plan for the diagnosis, treatment, and reablement of the tuberculous, and also emphasised that all nurses, whether or not engaged in tuberculosis work, should be tuberculin tested and that negative reactors should be offered B.C.G. vaccination.

HOSPITAL ADMINISTRATION

The present structure of external hospital administration was examined by a special committee, which concluded that it was unnecessary at this time to make radical alterations. Nevertheless, the present groupings and areas are not to be regarded as sacrosanct, and after further administrative experience the present groupings and areas should be reviewed. The Minister was finally advised that area committees of regional boards should be abolished in due course, or regional areas redrawn to avoid the need for these committees. In special circumstances a regional board should be allowed to administer a convalescent home or other ancillary unit in an area controlled by another board. It was suggested that capital allocations to boards should be spread over more than one year, and that hospital management committees should be given money for small capital works. The Minister was reminded that it was desirable to appoint at least one general practitioner and one medical officer of health to each regional board.

A committee has now been appointed to report on internal administration in individual hospitals, with particular reference to: (1) finance, staff, and supplies, (2) administration in relation to the different types of hospitals, and (3) the extent to which administrative duties should be undertaken by medical and nursing staff.

PRESCRIBING

A joint committee was set up with the Scottish Health Services Council to consider whether general practitioners should prescribe drugs of doubtful value or of unethical character, or unnecessarily expensive brands of standard drugs. The committee recommended that there should be no absolute restriction on the prescribing by a general practitioner of any drug which, in his opinion, is necessary for the treatment of his patient, and that he could freely prescribe all drugs and preparations described in the *British Pharmacopœia*, the *British Pharmaceutical Codex*, and the *National Formulary*,

compared with married women under the age of 45 At 20–24 the rate for single is 25% above that for married women, and at 25–34 it is 42% higher Probably the group of single women aged 16–44 is biased by containing a number who have remained single because they are tuberculous Moreover, the chance of dying in childbirth, which formerly constituted a grave threat to married women under the age of 45, has been greatly reduced, chiefly owing to the control of sepsis with sulphanilamides The mortality-rate of women in or associated with pregnancy and childbearing fell from 3 80 per 1000 live and still births in 1934 to 1 02 in 1947 in cases without abortion while the rate for cases with abortion declined from 0 82 to 0 16 Suicide and accidental deaths are two other causes in which the death-rates for single women under 45 are higher than those for the married As regards suicide, perhaps the neurotic disposition which finds an outlet in suicide may also have prevented marriage As regards accidents, a number of deaths would be due to accidents either at work or on the journey to and from the place of employment At 45–64 single women had higher rates than did married women for respiratory tuberculosis pneumonia, peptic ulcer, suicide and accidental deaths, but married women's rates showed a substantial excess over those of single women for diabetes, cerebrovascular lesions, arteriosclerosis, and nephritis

TABLE V—ACTUAL AND EXPECTED AGE DISTRIBUTIONS OF MARRIED AND SINGLE WOMEN RECORDING A MONTH'S SICKNESS EXPERIENCE

Age group (yr)	Married			Single		
	Actual	Expected	Difference	Actual	Expected	Difference
16–24	2016	1760	+256	3138	3473	−335
25–34	6427	5905	+522	1455	1225	−230
35–44	6522	8354	−183	893	981	− 88
45–54	4949	5136	−187	931	882	− 49
55–64	3196	3577	−381	767	680	− 87
65–74	1501	1764	−263	565	502	+ 63
75 or more	361	416	− 55	261	267	− 6
Total	24 972	24 972		8010	8010	

In table III the adjusted mortality among married women is based on the number of deaths which would have occurred among married women had their age distribution been the same as that of the single Owing to the difference in death rates, 10 3% of the deaths of single women occur at ages under 30 compared with an adjusted rate of 8 4% among married-women A quarter of the single women's deaths take place before the age of 55, whereas 21 6% of married women's deaths would occur before that time if their age-distribution was the same as that of the single women

The Social Survey interviewed in each month of 1948 a sample of about 3000 people aged 16 or more, to obtain their sickness experience during the two months preceding the interview Hence in the course of a year about 70,000 persons recorded a month's sickness experience During 1948, 24,972 of these were married and 8010 single women (table IV) Their age distribution is shown in table V, and is compared with an expected distribution based on the age distribution of the two classes in the general population

For married women $\chi^2 = 186\ 53$ when $n = 5$, hence P is less than 0 001 For single women $\chi^2 = 103\ 43$ when $n = 5$, hence P is less than 0 001 The age-distribution of both the married and the single women whose sickness experience was recorded therefore differs significantly from that among the general population In the discussion which follows three principal age-groups are considered 16–44, 45–64, and 65 or more, but, since the age distributions of the two classes differ, two rates have been calculated for single women—the actual rate, and that which would obtain if the age-distributions were comparable

TABLE VI—NUMBER REPORTING NO ILLNESS OR INJURY DURING JANUARY–DECEMBER 1948 PER 100 MARRIED AND SINGLE WOMEN INTERVIEWED

Dr John Ayrton Paris, president of the Royal College of Physicians, told them that it was for them and for them alone to determine what should be the future state of the profession The lifelong interest of Hastings, however, was the welfare of the provincial practitioner, and it was not until the Provincial Medical Association had been in existence for twenty four years that he agreed to the wish of the majority to change in the title the word "Provincial" to "British"—an amendment first proposed in these columns some years earlier[1] Dr McMenemey's lecture was illustrated by lantern slides, which included a number of portraits of those early pioneers of the association who assisted Hastings i project

In the famous boardroom of the Worcester Infir wherein the inaugural meeting was held, visitors sa exhibition of records illustrating the work of Has including several of his publications

The British Medical Association, and particularl Worcester and Bromsgrove division, is to be congratu on this first Charles Hastings Festival, so happily ciding with the Festival of Britain Their decisi commemorate the founder every few years in a Se of rededication to the objects of the association is n a happy one

Public Health

DEATH-RATES AND SICKNESS-RATES OF MARRIED AND SINGLE WOMEN IN 1948

EILEEN M BROOKE
M Sc Lond
STATISTICIAN, GENERAL REGISTER OFFICE, LONDON

A COMPARISON has been made of the death rates and sickness rates of married and single women, based on the Registrar General's returns of death and the Survey of Sickness figures derived from monthly interviews held by the Central Office of Information on behalf of the General Register Office Widows and divorcees have been excluded from the analysis for two main reasons First, the group of single women may contain a number whose celibacy is due to bad health and poor physique, and whose sickness rate would therefore be above the average It would not be practicable to include the widowed and divorced with this group, since no such sanction has applied in their case Alternatively, since some single or divorced women, especially in the lower age groups, might be in a worse position economically than married women, with consequent repercussions on their health, it would be inadvisable to include them with the married group That age specific death rates are not greatly influenced by the inclusion of the widowed and divorced with either the single or married groups except at the higher ages is illustrated by table I

The lower age limit in the table has been set at 16 years because for National Insurance purposes this is the age at which working life is presumed to begin, the same lower limit has been taken in the Survey of Sickness The death rates of single women are higher than those of the married in all quinquennial age-gr under 60 At ages under 45 the ratio (1 34) of the for single to that for married women is lowest at 20–24, whereas at ages 25–34 single women have a slightly more than 50% higher than that of the ma At ages from 45–64 the rate for single exceeds tha married women, but less markedly, the ratio va between 1 00 and 1 19 Unfortunately there i information more recent than that obtained at 1931 census to show which individual causes of d are mainly responsible for the excess

TABLE I—DEATH RATES PER 10,000 WOMEN BY MARITAL S IN 1948

Age group (yr)	Single	Married	Ratio of single to married	Single widowed and divorced	Marr widow an divor
16–19	11 9	8 5	1 40	11 9	8

	S	10	11	9	10	18	33	59	219

* Blanks in this table denote that for the cause age-status group concerned less than 20 deaths were recorded

lays a doctor's certificate is not required, there may be tendency on the part of single women to forget to eport minor illnesses, where they would remember an occasion on which they had consulted a doctor They nay also show a greater tendency to disregard minor nd symptomatic illnesses, and to continue at work n spite of feeling ill, so as to avoid the financial loss onsequent on obtaining a doctor's certificate and being way from work for a week In this connection it is well nown that, among piece workers who combine to orm a team, each member will make great efforts to void being away because of the monetary loss to the thers Further, in 1948 married women may have had a preponderance of minor complaints connected with child bearing and fatigue due to queueing, carrying heavy shopping baskets, and inability to obtain domestic help The inception rates of minor and ill defined illnesses show a fairly definite seasonal trend (see figure)

If all illnesses be considered, instead of only those starting or recurring during a certain period, it is found that in each quarter of 1948 the rates for married women in the age group 16–44 were from $1^{1}/_{4}$ to $1^{1}/_{3}$ times greater than those for single women, and, even when the variation in age structure between the two groups is allowed for, the married still show much higher rates than do the single women (table VIII) In the age group 45–64 single women had a higher rate in the first quarter and married women in the remaining nine months, while for ages over 65 married women had higher rates than single during the six months April September Taken over the whole year, there is very little difference between the rates for single and married women at ages 65 or more

TABLE IX—DAYS OF INCAPACITY AND NUMBERS OF MEDICAL CONSULTATIONS PER 100 MARRIED AND SINGLE WOMEN INTERVIEWED

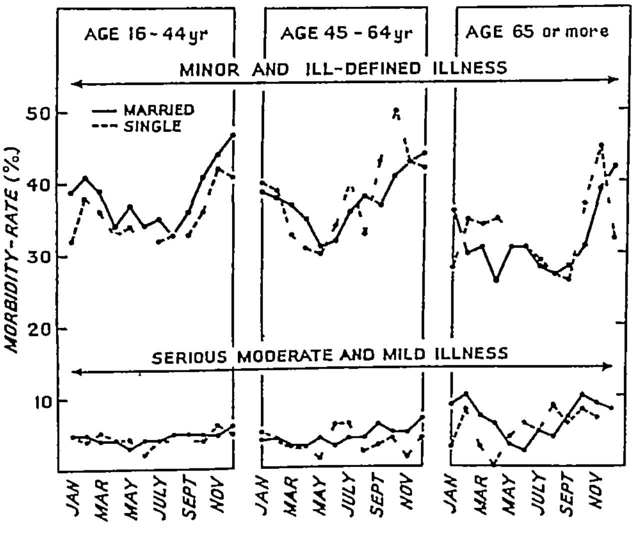
Table VI shows that for each month of the year, in the age group 16–44, proportionately more single than married women reported freedom from any illness or injury The excess in the percentage number of single over married women who were sickness free varied between 13 in January and 6 in May If the adjusted numbers for single women be considered, they still exceed the numbers of married women who reported no illness or injury In the age group 45–64 a higher proportion of single than married women reported freedom from sickness except in January and February At ages over 65 there was no significant difference between the two groups, but the seasonal range was greater in the case of single women, the successive quarterly proportions being 16, 17, 21, and 9%, compared with 18, 19, 16, and 15% among the married On the whole there was more freedom from sickness during April to September than during the remaining six months, at all ages and in both classes

Table VII shows the inception rates for new and recurrent illnesses reported for each month, a recurrent illness in this context being an attack which occurs not less than a week after the subsidence of a previous attack of the same malady Distinction is made in this table between (1) serious, moderate, and mild illnesses, all of which generally produce three or more days' incapacity, and (2) minor and ill defined illnesses, of which the former are diagnostic entities generally causing incapacity lasting less than three days and the latter are complaints listed in numbers 773 and 780–795 of the International Classification of Diseases, 1948 Where serious, moderate, and mild illnesses are concerned, there is little difference between the inception rates for married and single women, and if the figures be aggregated over the year, the percentage rates in the age groups 16–44 and 45–64 show no difference between the two classes There is a slight variation between them from month to month, but in none of the three age groups is there a very striking seasonal pattern of variation



Monthly inception-rates of new and recurrent illnesses per 100 married and single women

TABLE VIII—PREVALENCE RATES (TOTAL ILLNESSES PER 100 MARRIED OR SINGLE WOMEN)

When minor and ill defined illnesses are considered, married women in the age group 16–44 show a consistently higher inception rate month by month than do single women If the figures for the year be aggregated, married women in this age group have an inception rate of 39%, compared with an adjusted rate of 37% among single women, the difference between the two percentages is significant, but not highly so (Difference = 1 98, 2S E = 1 66) The inception rates for minor illnesses in this group are 30 5% for married and 29 5% for single women, those for ill defined and symptomatic diagnoses are 8 2% and 5 7% respectively At 45–64 and over the age of 65 there are no consistent differences between the combined rates for minor and ill defined illness in the single and married

One explanation of the difference between the two classes at 16–44 may be that a greater proportion of single than married women in this age group is working, and, since for an absence from work of less than three days a doctor's certificate is not required, there may be a tendency on the part of single women to forget to report minor illnesses, where they would remember an occasion on which they had consulted a doctor They may also show a greater tendency to disregard minor and symptomatic illnesses, and to continue at work in spite of feeling ill, so as to avoid the financial loss consequent on obtaining a doctor's certificate and being away from work for a week In this connection it is well known that, among piece-workers who combine to form a team, each member will make great efforts to avoid being away because of the monetary loss to the others Further, in 1948 married women may have had a preponderance of minor complaints connected with child bearing and fatigue due to queueing, carrying heavy shopping baskets, and inability to obtain domestic help The inception rates of minor and ill defined illnesses show a fairly definite seasonal trend (see figure)

If all illnesses be considered, instead of only those starting or recurring during a certain period, it is found that in each quarter of 1948 the rates for married women in the age group 16–44 were from $1^1/_4$ to $1^1/_3$ times greater than those for single women, and, even when the variation in age structure between the two groups is allowed for, the married still show much higher rates than do the single women (table VIII) In the age group 45–64 single women had a higher rate in the first quarter and married women in the remaining nine months, while for ages over 65 married women had higher rates than single during the six months April September Taken over the whole year, there is very little difference between the rates for single and married women at ages 65 or more

Table IX shows the days of incapacity and numbers of medical consultations for each hundred married and single women Although at 16–44 married women had higher prevalence rates than did single women, the

When minor and ill defined illnesses are considered, married women in the age group 16–44 show a consistently higher inception rate month by month than do single women If the figures for the year be aggregated, married women in this age group have an inception rate of 39%, compared with an adjusted rate of 37% among single women, the difference between the two percentages is significant, but not highly so (Difference = 1 98, 2S E = 1 66) The inception rates for minor illnesses in this group are 30 5% for married and 29 5% for single women, those for ill defined and symptomatic diagnoses are 8 2% and 5 7% respectively At 45–64 and over the age of 65 there are no consistent differences between the combined rates for minor and ill defined illness in the single and married

One explanation of the difference between the two classes at 16–44 may be that a greater proportion of single than married women in this age group is working, and, since for an absence from work of less than three veins, with the Bateman needle, is the best all round route for really severe cases. An additional reason is that these cases may need chemotherapy,[1] in addition to plasma[2] and amino-acids, by the intravenous route, often maintained for a week or longer; scalp veins are unsuitable for this purpose.

Sound technique should ensure an almost invisible scar as was found to be the rule in our patients, whose subsequent physical and mental development, to our surprise, was higher than the average. By fixing a sterile cotton-wool filter to the air inlet, sepsis is effectively eliminated; alternatively, merthiolate (1 : 20,000) can be added to the drip fluid. It is a salutary lesson to examine bacteriologically the last few ml. of each infusion solution, especially when plasma is added. When chemotherapy is given during the period of intravenous administration these measures may be dispensed with, but they represent the better practice, as the commonly found organisms—coliforms, staphylococci, &c.—may be drug resistant.

London N.W.3 WILLIAM GUNN

THE MEDRESCO HEARING-AID

SIR,—Several conclusions not mentioned by Mr. Gray and Miss Cartwright can be reached from their article of May 26. One is that the number of hours' use per day of the 'Medresco' aid is well below the original estimate. Another is that the first aim of design—namely, to make speech understood—has only been partially achieved. Doubtless there is a direct connection between these two facts.

According to table II of the report 55·3% of the patients interviewed used their aids for less than four hours per day during the previous week. Only about 60% of the patients who went shopping or out of doors used the aid on these occasions. The actual position is probably even worse, for most patients would be on the defensive when being questioned and would be likely to exaggerate the daily use. Making allowances for these factors the figures compare reasonably well with the estimates from other sources that two thirds of the medresco aids issued receive little use after the first few weeks.

The article mentions that patients complain greatly of the size and weight of the batteries and that only 65% are able to repeat all the words from a list reproduced at 3 ft. from the instrument. Surely this is a simple test, and the poor results achieved must mean that little benefit is derived from the aid in group conversation, in meetings, and at the theatre.

Gray and Cartwright state that half the patients are from households where the weekly income of the head is £5 per week or less. It is these patients who, in general, need the greatest help; they are usually on the receiving end of speech, nor are they able to ask their superiors to repeat what has been said. Their instruments must be convenient and inconspicuous if they are not to be handicapped by their deafness. They cannot possibly derive sufficient benefit from an aid that weighs nearly 2 lb. in its lighter form, has a low degree of speech intelligibility, and is handed out at the rate of 2000 per week. Would it not be better to confine the scheme to patients in real need and to give them the best available hearing aid and careful guidance in rehabilitation?

Good commercial hearing aids can offer many advantages that are not available in the medresco. Most hearing aid manufacturers make a range of instruments and earphones giving several variations of tone. Maximum power output can be varied with the type of instrument and through provision of automatic volume compression. These aids weigh about 5 oz. and are robust and convenient in use. Great attention is paid to individual fitting. Patients are seen after one week and frequently during the first few months to check the fitting and to receive further guidance. Service is usually on a while-you-wait basis and postal service, and batteries are supplied in 24 hours.

The cost of use of a good commercial hearing aid is easily calculated. The figures below are based on a daily average use of 4·9 hours, as for the medresco. They ignore part exchange allowance on the old aid and interest on capital employed.

	Per week s	*Per week* d
Battery use at ¾d. per hour	2	2
Service on a subscription basis at £2 10s. per annum	1	0
Two earphone cord replacements at 6s. 6d. each	0	3
Cost of aid at £25 every five years	2	0
Total cost of aid and maintenance	5	5

These figures suggest that there is little justification for continuing so extravagant a scheme as the wholesale manufacture and distribution of the medresco aid, bearing in mind how little it contributes to complete hearing rehabilitation. The aid is so bulky and heavy that it is inconvenient in use and is left at home, while the degree of speech intelligibility is comparatively low and does not justify the bother of carrying it about. There is little attempt at education in the use of the aid; indeed this would be impossible with a distribution of 2000 per week.

Would it not be better at this juncture to devise a Government scheme to give the greatest benefit where it is most needed, and to withdraw it entirely from those who make so little use of it or who can afford to pay for a commercial aid? Surely 5s. 5d. per week is within the reach of most people, many of whom could increase their earnings through the use of a good instrument. How much better it would be for the deaf if the hearing aid industry and the Ministry of Health could coöperate in fitting and service, leaving the Medical Research Council and the Post Office to provide a background of fundamental research.

SICKLE-CELL ANÆMIA IN GREECE

SIR,—Professor Choremis and his colleagues, in their article of May 26, bring evidence for the existence of the sickle cell trait amongst the inhabitants of Petromagoula. The fact that the individuals showing sicklæmia were also anæmic does not, however, justify a diagnosis of sickle cell anæmia—i. e., of an anæmia caused by sickle cell hæmolysis. Anæmia, a high serum bilirubin, and an enlarged spleen are findings not unexpected near "a swamp which was dried out by an English company a few years ago," a location which "comprised one of the most malaria stricken areas of Greece." Jaundice, abdominal pain ("crises"), joint pain, pyrexia, and an enlarged spleen—all are common to both malarial and sickle cell anæmia. If the parasites are not discovered the only means of differentiation is the response to antimalarial treatment.

Ultimate positive proof for the existence of a sickle cell anæmia involves an exchange transfusion demonstrating the abnormally short lifespan of the patient's red cells. This is, of course, impracticable in the field. In the few cases of sickle cell anæmia which I was able to find in Uganda—where the rarity of the disease contrasts strangely with the high incidence of the trait—it was noteworthy that the red cells showed an increased resistance to hypotonic salt solutions (only partial hæmolysis in 0·28% sodium chloride[1]). This lowered red cell fragility differentiated sickle cell anæmia from malarial and other hæmolytic anæmias where the fragility is usually raised.

Letters to the Editor

PNEUMOCONIOSIS IN COALMINERS

SIR,—We welcome your leading article last week, which gives a timely reminder to the world of medicine of the importance of this disease and of some of the proposals that are being made for its control

You appear, however, to contrast those who wish to prevent pneumoconiosis by dust suppression with those who wish to see periodic examinations used for its control, and you imply that we fall only into the latter group This implication is mistaken, there is no antithesis between the two methods of approach The final proof of the adequacy of dust suppression must be biological, and, we think, a system of periodic examinations is the best way of achieving it Without such examinations the excellent work now being done to suppress dust must lack the test of its efficiency which the engineers seek [1] Without medical evidence it will be impossible to establish safe levels of dustiness in the pits

Your article suggests to us that there are still some misunderstandings about the nature of coalworkers' pneumoconiosis We maintain that radiological signs of coalworkers' pneumoconiosis appear before the condition can in any way be described as a disease, and that even advanced *simple* pneumoconiosis is seldom a cause of serious disability Therefore, if men were advised to work in less dusty conditions before they have developed sufficient simple pneumoconiosis to become liable to massive fibrosis (not *after* they have developed this degree of simple pneumoconiosis, as you state), then they should be saved from the most serious disabling effects of the disease Massive fibrosis may advance independently of further dust exposure and does cause severe disability These facts enable radiological examination to be used for evaluating the adequacy of dust suppression, and at the same time to control a scheme of prophylactic medicine by warning miners of the necessity to reduce their dust exposure when they have reached a certain stage of simple pneumoconiosis It should be stressed that these facts contrast with the evidence available about silicosis A workman may leave a silicotic risk with a normal radiograph and develop severe silicosis later,[2] thus rendering prophylactic medicine by the use of radiology far less effective

In spite of what Meiklejohn says, we believe that our scheme is perfectly practicable It is confined to radiological examination because we know of no evidence to suggest that clinical examinations can assist in determining the prognosis in simple pneumoconiosis, whereas we have good evidence about the prognostic value of radiology We have considerable experience suggesting that the statement about "mass psychosomatic disorder" is a gross exaggeration All medical examinations run a small risk of producing some neuroses, but if periodic radiological examinations are well administered the risks will be negligible Indeed, there is evidence from other industries that they improve morale and aid recruitment A pilot scheme of examining miners at 20 representative pits which we have proposed would show how the men would react to examinations and whether an extension to the whole industry would really be as difficult as Meiklejohn's timid estimates suggest

You ask what test could be applied to doctors to prove their ability to diagnose early simple pneumoconiosis in radiographs in the absence of pathological confirmation A simple and valid test would be to see whether the doctors could distinguish the radiographs of men who had had dust exposure from those of men who had not A doctor who diagnoses pneumoconiosis from the film of a man without any history of exposure to dust and fails to diagnose it where his more experienced colleagues can do so confidently and correctly, should surely be regarded as insufficiently expert to undertake this work This type of study should gradually convince the doubting "chest physicians," whom you quote, that there are radiographic signs truly characteristic of dust exposure

While we agree with you that the Pneumoconiosis Medical Panels have the confidence of the men, the evidence which you quote for this confidence, given by Mr Harold Neal in the House of Commons, might equally be taken as evidence of economic pressure in South Wales [3] We agree that a widening of the work of the Pneumoconiosis Panels would be a possible way of providing periodic examinations, but we would rather see preventive medicine separated from compensation

You quote Meiklejohn's suggestion that the employers should provide certificates of fitness for the working places You do not say on what basis this certificate is to be granted On the basis of an arbitrary level of dustiness without any medical justification? Surely it should be based on the demonstration by periodic examinations that the men working in these places are not developing any evidence of pulmonary abnormality

Space does not allow for detailed comment on some other points for instance, the accuracy of early radiological diagnosis of silicosis has never been determined and there is reason to believe that it would be similar to that of pneumoconiosis, again, the value of pre employment radiographs is very limited unless followed by periodic examinations later

At present, the National Coal Board are spending large sums of money on dust suppression Your fear that emphasis on periodic medical examination will lead to such effort being "ignored" is surely rather absurd, and we claim that such examinations would lead to a more efficient direction of the engineering work

Your article suggests that to prevent pneumoconiosis the engineers should get on with the job of dust suppression unassisted by medical study We consider it unfortunate that you should advocate a policy contrary to the established practice—the full cooperation of doctor and engineer We want to see them working hand in hand to ensure the eradication of this serious disease from British coalmines

INTRAVENOUS FLUID THERAPY IN *CHILDREN*

SIR,—It would be unfortunate if Dr Mann's statement last week that cutting down is a "bad procedure" were accepted at its face value Experience has shown that in really malignant infantile gastro enteritis cases it is the best life saving measure, these are not comparable to the prevalent mild types responding to a single drip, many of which would recover equally well without parenteral fluid

The use of warmth, oxygen (in a tent), and oral Hartmann's solution (without glucose) can convert an ill, even a dehydrated and shocked, patient into a recovering one in a matter of hours continuance of vomiting and profuse diarrhœa after admission, however, are indications for intravenous fluid therapy I have used the subcutaneous and intramuscular routes (with and without hyaluronidase), the peritoneal cavity, the longitudinal sinus, and scalp veins in turn and at the same periods, and have come to the conclusion that the limb veins, with the Bateman needle, is the best all round route for really severe cases An additional reason is that these cases may need chemotherapy,[1] in addition to plasma [2] and amino acids, by the intravenous route, often maintained for a week or longer, scalp veins are unsuitable for this purpose

Sound technique should ensure an almost invisible scar as was found to be the rule in our patients, whose subsequent physical and mental development, to our surprise, was higher than the average By fixing a sterile cotton wool filter to the air inlet, sepsis is effectively eliminated, alternatively, merthiolate (1 20,000) can be added to the drip fluid It is a salutary lesson to examine bacteriologically the last few ml of each infusion solution, especially when plasma is added When chemotherapy is given during the period of intravenous administration these measures may be dispensed with, but they represent the better practice, as the commonly found organisms—coliforms, staphylococci, &c—may be drug resistant

London N W 3 WILLIAM GUNN

THE MEDRESCO HEARING-AID

SIR,—Several conclusions not mentioned by Mr Gray and Miss Cartwright can be reached from their article of May 26 One is that the number of hours' use per day of the 'Medresco' aid is well below the original estimate Another is that the first aim of design—namely, to make speech understood—has only been partially achieved Doubtless there is a direct connection between these two facts

According to table II of the report 55 3% of the patients interviewed used their aids for less than four hours per day during the previous week Only about 60% of the patients who went shopping or out of doors used the aid on these occasions The actual position is probably even worse, for most patients would be on the defensive when being questioned and would be likely to exaggerate the daily use. Making allowances for these factors the figures compare reasonably well with the estimates from other sources that two thirds of the medresco aids issued receive little use after the first few weeks

The article mentions that patients complain greatly of the size and weight of the batteries and that only 65% are able to repeat all the words from a list reproduced at 3 ft from the instrument Surely this is a simple test, and the poor results achieved must mean that little benefit is derived from the aid in group conversation, in meetings, and at the theatre

Gray and Cartwright state that half the patients are from households where the weekly income of the head is £5 per week or less It is these patients who, in general, need the greatest help, they are usually on the receiving end of speech, nor are they able to ask their superiors to repeat what has been said Their instruments must be convenient and inconspicuous if they are not to be handicapped by their deafness They cannot possibly derive sufficient benefit from an aid that weighs nearly 2 lb in its lighter form, has a low degree of speech intelligibility, and is handed out at the rate of 2000 per week Would it not be better to confine the scheme to patients in real need and to give them the best available hearing aid and careful guidance in rehabilitation ?

Good commercial hearing aids can offer many advantages that are not available in the medresco Most hearing aid manufacturers make a range of instruments and earphones giving several variations of tone. Maximum power output can be varied with the type of instrument and through provision of automatic volume compression These aids weigh about 5 oz and are robust and convenient in use Great attention is paid to individual fitting Patients are seen after one week and frequently during the first few months to check the fitting and to receive further guidance Service is usually on a while you wait basis and postal service, and batteries are supplied in 24 hours

The cost of use of a good commercial hearing aid is easily calculated The figures below are based on a daily average use of 4 9 hours, as for the medresco They ignore part exchange allowance on the old aid and interest on capital employed

	Per week s	 d
Battery use at ¼d per hour	2	2
Service on a subscription basis at £2 10s per annum	1	0
Two earphone cord replacements at 6s 6d each	0	3
Cost of aid at £25 every five years	2	0
Total cost of aid and maintenance	5	5

These figures suggest that there is little justification for continuing so extravagant a scheme as the wholesale manufacture and distribution of the medresco aid, bearing in mind how little it contributes to complete hearing rehabilitation The aid is so bulky and heavy that it is inconvenient in use and is left at home, while the degree of speech intelligibility is comparatively low and does not justify the bother of carrying it about There is little attempt at education in the use of the aid, indeed this would be impossible with a distribution of 2000 per week

Would it not be better at this juncture to devise a Government scheme to give the greatest benefit where it is most needed, and to withdraw it entirely from those who make so little use of it or who can afford to pay for a commercial aid ? Surely 5s 5d per week is within the reach of most people, many of whom could increase their earnings through the use of a good instrument How much better it would be for the deaf if the hearing aid industry and the Ministry of Health could coöperate in fitting and service, leaving the Medical Research Council and the Post Office to provide a background of fundamental research

around the stellate ganglion (this naturally was associated with a Horner's syndrome), and I stated that equally gross dilatation of the same vessels occurred after injection around the 2nd and 3rd dorsal ganglia by the posterior route which did not result in a Horner's syndrome, therefore D1 must have been unaffected by the anæsthetic This proved conclusively that the nerve roots to D1 do not carry the majority—if indeed any at all—of the preganglionic vasomotor fibres for the vessels of the head and neck, for there was dilatation of the vessels of the conjunctiva, but there was no constriction of the pupil nor any narrowing of the palpebral fissure

You further state that I did not give my criteria for diagnosis or assessment of results I had dealt with the criteria for diagnosis in earlier papers,[1] and time did not permit of their repetition I did, however, give a method of exact selection by previous procaine block, and a detailed assessment of the results in 110 cases of Meniere's disease, tinnitus, and nerve deafness All my cases had been subjected to medical treatment without any material benefit, therefore I feel that sympathectomy (which by the way is neither ‘complicated’’ nor “hazardous”) is fully justified by the results

London W 1 E R GARNETT PASSE

Parliament

Hospital Finances

IN the House of Lords on May 30 the Marquess of READING asked the Government whether they would appoint such a committee as they might think appropriate to inquire into, and report on, the operation of the system under which the finances of hospitals coming within the scope of the National Health Service Act, 1946, were at present administered, and moved for papers

He said it was not part of his argument to suggest that there should be any reduction of the services rendered by hospitals to the public, nor to suggest that the public making use of the services should be invited or compelled to make any greater financial contribution than at present He was asking for no more than that the Government should institute an inquiry into the operation of the present system, with the inference that if, as a result of that inquiry, it was found to be unsuitable, and a more suitable system could be found, the recommendation would be in favour of such a system as the committee proposed It was at least possible that, by revision of the financial system, very substantial retrenchment could be effected One of the difficulties was that there were no uniform costing standards, but, said Lord Reading, he understood that an investigation on this was now being carried out Some interchange between the Ministry and those responsible for the day-today administration of hospitals might adequately inform one group of the difficulties confronting the others. The system by which the savings of a careful hospital in a group might be filched and handed to a careless hospital was objectionable in practice and principle It discouraged and frustrated those who were making a determined effort to save public money to use it in a proper priority of needs Lord Reading thought that the weakness of the present system was that it was centralised, rigid, and wasteful He hoped that the Government would not procrastinate, but that they would make sure that the committee of inquiry was composed of people well qualified to carry out an onerous but essentially worth while task, thereby opening up the possibility of effecting a real saving of what was at present a most costly branch of the public service

Lord AMULREE said he felt that it was very proper and sensible to impose some kind of ceiling to expenditure on the National Health Service Care must, however, be taken to see that the economies were real and genuine, it would be quite easy to make a number of false economies Money could be saved by shutting down hospital wards or by cutting staffs, but that would produce only a secondary service instead of a first-rate one The country as a whole would not be party to such a policy It would be much better that this matter should be inquired into by an independent committee rather than by a department of the Ministry or the Treasury, because they were busy with other matters and had not the time to consider any of these questions with the quietness and calmness which they required The problem was not at all simple, because it was very difficult to find any convenient yardstick which would cover all the various types of hospital in the country Quite obviously, a teaching hospital in London would require more money proportionately to its patients than would some small cottage hospital in the country He was pleased to see that the Ministry had requested the Nuffield Provincial Hospitals Trust and the King Edward's Hospital Fund for London to make an inquiry into hospital costing But he rather doubted whether that inquiry would provide the final answer to the question, because he did not think it would take into consideration the differences in the running of the different types of hospital

It should be possible to arrive at the cost of inpatient treatment and outpatient treatment in the various types of hospital, and to pay each hospital a capitation fee Such a system would ensure that hospitals would try to achieve a reasonably quick turnover of beds, thus reducing the waiting-lists Block grants were a good way of financing hospitals because they were subject to a five-year revision. The system by which certain consultants on the staffs of hospitals were paid merit awards could affect the running of the hospital If some doctor was granted a merit award that sum became an additional burden on the maintenance charges for the period that he remained with the hospital The money required to make up that sum was taken from the hospital. It was very largely a paper transaction from the Treasury point of view, but from the hospital point of view it might be a serious cut

Lord SHEPHERD, for the Government, said that, except for one or two modifications, the system of estimating the costs of the hospital services was the same today as it had been from the start of the scheme There were few instances in the country, public or otherwise, where better arrangements were in force for governing finances If estimating was much more strictly dealt with today than it was a year ago that was not because of any change of policy on the part of the Government or the Minister, but because of a change of international circumstances which made it necessary to rearm The Minister looked upon the hospital service as a developing institution and likely to call upon Parliament for greatly increased grants in the next few years unless rearmament rendered such development out of the question Inevitably, normal developments would cost a great deal of money because of increased prices All the management committees and regional boards were equally anxious that their hospitals should be developed, and for that purpose they would require money from the Government The most effective way in which applications could be made was by enabling them to put through estimates upon the basis of whether they could make out their case to the Minister Merely to get rid of these estimates and bring in block grants would not reduce the claims of the hospital services The working of a priority system would be impossible were it merely a case of a block grant being applied for It could be properly carried out only when full estimates were placed before the authorities who had to give the decision. The unspent balances which might exist at the end of a year were not cash If a hospital authority had not exhausted its authority to spend and a balance remained, it merely lapsed This question of spending balances towards the end of a year had to be determined not by principle but according to the circumstances of the time A case had not been made out for the appointment of a committee of inquiry Hospital accounts were investigated by the Public Accounts Committee and the Estimates Committee The latter was giving special attention this year to the hospital service, and evidence would be given before it by officers of the Ministry, representatives of two regional boards, three management committees, the Royal College of Surgeons and the Royal

STEVENS-JOHNSON SYNDROME

SIR,—The article by Dr Ashby and Dr Lazar in your issue of May 19 prompts me to record three cases successfully treated with 'Aureomycin'

CASE 1—A married woman, aged 29 years, was seen on May 5, 1950 Pruritus vulvæ had been present for three days and sore throat for two days Ulceration of lips and mouth had started twenty four hours previously, and was rapidly worsening The previous day she had been given penicillin 300,000 units

When seen, the patient had a temperature of 99°F, and severe ulceration of lips, buccal mucosa, tongue, and pharynx, with a membrane on the surface of the ulcers The mouth could hardly be opened, and she had severe dysphagia The palms and soles were of a blotchy red colour and were itching, and she had two erythematous patches on the dorsum of the feet She complained of pruritus in the rectum and vagina, but as her period was on, these areas were not examined The cervical lymph glands were markedly enlarged and tender, but no other lymph glands were enlarged and the spleen was not palpable The lungs were clear The heart rate was 110 per min, and a loud pericardial rub was present The eyes were normal

Stevens Johnson syndrome was diagnosed and aureomycin started immediately—0 5 g followed by 0 25 g six hourly through the night The following morning she was transferred to a R A F hospital where aureomycin therapy was continued Improvement was rapid and dramatic Within forty eight hours of starting treatment she was non toxic, and sloughs were separating in the mouth, and five days after admission she had made a complete recovery Altogether 6 g of aureomycin was administered

CASE 2—A man, aged 69 years, seen on Sept 23, 1950, had for the past eighteen months suffered from neurasthenia Four months previously he had noticed a "lump on the left eye which spread to the right eye," and later raised red areas on the hands and sores on the lips This condition cleared in three weeks without treatment On Sept 3 he had developed severe conjunctivitis, and the rash reappeared on the hands, Two weeks later the lips became ulcerated, and he had pruritus in the rectum

When seen as an outpatient he had numerous ulcers on pharynx, buccal mucosa, tongue, and lips a yellow slough covered the buccal ulcers, and the lips bled readily On the dorsum of the hands and wrists were several dusky red indurated areas, some with tiny yellow vesicles There was no glandular enlargement, and no detectable abnormality of heart, lungs, abdomen, or central nervous system There was marked blepharitis and conjunctivitis He was admitted to hospital, where he was found to have a temperature of 99–100°F, heart rate 100 per min., blood pressure 160/95 mm Hg, and total leucocytes 7200 per c mm

He was given aureomycin 0 25 g six hourly, and in forty eight hours the lesions in the mouth were regressing and eyes improving rapidly At the end of a week all lesions had cleared except the skin lesions on hands Aureomycin was continued for three weeks, to try and prevent exacerbation, altogether 21 g was administered When he was discharged on Oct 18, all lesions had cleared He was seen as an out patient on March 3, 1951, with recurrence of ulcers in the mouth These were still present a fortnight later, but cleared without treatment in a further week

CASE 3—A married women, aged 60, had had sore bleeding lips since an attack of quinzy three years before, this had been treated by sulphathiazole and penicillin and later an autogenous vaccine (*Staphylococcus aureus*) One month before admission a rash had appeared on the body which had spread rapidly

When seen on Oct 8, 1949, she had ulcerated, bleeding lips and large, red, raw weeping areas over the greater part of the anterior aspect of both legs and thighs, the forearms, the lower abdominal wall, and about one third of the back Near the edges of the raw areas were numerous, almost confluent, vesicles up to 1 cm in diameter on a dusky red base, many of these were breaking down There were no abnormal signs in the heart, lungs, or central nervous system She was severely toxic and was admitted immediately Her leucocyte count was 18,800 per c mm with 8% eosinophils Temperature 97 6°F

She was given aureomycin 0 25 g six hourly Within twenty four hours the vesicles were drying, and her general condition had dramatically improved The raw areas began to become epithelialised within three days Treatment with aureomycin was continued until Nov 17, when further supplies of the drug were unobtainable Yellow capsules containing sodium bicarbonate were substituted, and within two days fresh vesicles appeared and her general condition deteriorated When aureomycin was started again on Dec 1, her condition again improved rapidly, and she was discharged on Feb 22 1950, with all lesions healed except for small fissures on the lips Altogether 113 g of aureomycin had been administered Since discharge she has been seen regularly as an outpatient The ulceration of the lips remains unchanged Occasionally a red indurated area has appeared on the legs or arms, but these have cleared with Lassar's paste Her general condition remains excellent

Case 1 was the most acute, and responded most rapidly, and the presence of pericarditis is noteworthy Case 3 was not so obviously benefited; but the patient's rapid relapse when the drug was discontinued, although a visually identical placebo was being given, and her improvement on re starting the drug, makes its value seem highly probable

Deductions from such a small number of cases must be tentative, but aureomycin should be tried in all cases of this most distressing disease

Wing Commander H E Bellringer kindly provided me with notes about case 1 in the R A F hospital

London W 1 IDRIS JONES

THE BODY'S IRON

SIR,—Your leading article of April 14 gives a fine review of much of the recent work There is, however, one error to which I should like to call attention You quote me as saying "he puts the figures at 1 mg Fe daily for men, and at 15 mg daily for women of menstrual age" My remarks on this point actually were as follows

> "The daily loss of iron in fæces, sweat, etc, for normal adult men and women is probably between 0 5 and 1 mg To this figure, in adult women prior to the menopause, must be added an average of 1 mg per day to cover menstrual blood loss The amount of iron which must be assimulated by adult women, therefore, if they are to remain in iron balance, varies from about 1 0 to 2 0 mg per day If it is assumed that 10 per cent of the iron in food is absorbed, then women require a diet which contains 10 to 20 mg of iron per day"

The figure of "15 mg daily for women of menstrual age" for excretion of iron is much too high It would be almost impossible to assimulate this much iron from any reasonable diet

SURGICAL TREATMENT OF MÉNIÈRE'S DISEASE

SIR,—In your annotation of April 7, which refers to the symposium on this subject given before the Royal Society of Medicine by Mr Seymour, Mr Tappin, and myself, it is obvious that owing to the complexity of this subject not everything that was said by us was clearly comprehended

You say that interruption of the sympathetic outflow below D1 would, according to Smithwick, not denervate the main vascular supply to the head and neck A few months ago Smithwick was definitely not of this opinion, in fact he was of the opinion that it may be necessary to remove not only D2 and D3 but also D4 and possibly D5 I was pleased to read Professor Mitchell's letter (April 21), also disputing this assertion of D1 being responsible for most of the sympathetic vascular control to the head and neck Clinically, I am able to confirm the work of Hyndman, Wolkin, and Soetz that the majority of the preganglionic vasomotor sympathetic fibres for the head and neck are found in the 2nd thoracic nerve roots

In my paper, referred to above, I gave the following experimental evidence

> Slides were shown demonstrating gross dilatation of the vessels of the membrana tympani after injection of procaine

around the stellate ganglion (this naturally was associated with a Horner's syndrome), and I stated that equally gross dilatation of the same vessels occurred after injection around the 2nd and 3rd dorsal ganglia by the posterior route which did not result in a Horner's syndrome, therefore D1 must have been unaffected by the anæsthetic This proved conclusively that the nerve roots to D1 do not carry the majority—if indeed any at all—of the preganglionic vasomotor fibres for the vessels of the head and neck, for there was dilatation of the vessels of the conjunctiva, but there was no constriction of the pupil nor any narrowing of the palpebral fissure

You further state that I did not give my criteria for diagnosis or assessment of results I had dealt with the criteria for diagnosis in earlier papers,[1] and time did not permit of their repetition I did, however, give a method of exact selection by previous procaine block, and a detailed assessment of the results in 110 cases of Menière's disease, tinnitus, and nerve deafness All my cases had been subjected to medical treatment without any material benefit, therefore I feel that sympathectomy (which by the way is neither "complicated" nor "hazardous") is fully justified by the results

London W 1 E R GARNETT PASSE

Parliament

Hospital Finances

IN the House of Lords on May 30 the Marquess of READING asked the Government whether they would appoint such a committee as they might think appropriate to inquire into, and report on, the operation of the system under which the finances of hospitals coming within the scope of the National Health Service Act, 1946, were at present administered, and moved for papers

He said it was not part of his argument to suggest that there should be any reduction of the services rendered by hospitals to the public, nor to suggest that the public making use of the services should be invited or compelled to make any greater financial contribution than at present He was asking for no more than that the Government should institute an inquiry into the operation of the present system, with the inference that if, as a result of that inquiry, it was found to be unsuitable, and a more suitable system could be found, the recommendation would be in favour of such a system as the committee proposed It was at least possible that, by revision of the financial system, very substantial retrenchment could be effected One of the difficulties was that there were no uniform costing standards, but, said Lord Reading, he understood that an investigation on this was now being carried out Some interchange between the Ministry and those responsible for the day-today administration of hospitals might adequately inform one group of the difficulties confronting the others The system by which the savings of a careful hospital in a group might be filched and handed to a careless hospital was objectionable in practice and principle It discouraged and frustrated those who were making a determined effort to save public money to use it in a proper priority of needs Lord Reading thought that the weakness of the present system was that it was centralised, rigid, and wasteful He hoped that the Government would not procrastinate, but that they would make sure that the committee of inquiry was composed of people well qualified to carry out an onerous but essentially worth while task, thereby opening up the possibility of effecting a real saving of what was at present a most costly branch of the public service

Lord AMULREE said he felt that it was very proper and sensible to impose some kind of ceiling to expenditure on the National Health Service Care must however, be taken to see that the economies were real and genuine, it would be quite easy to make a number of false economies. Money could be saved by shutting down hospital wards or by cutting staffs, but that would produce only a secondary service instead of a first-rate one The country as a whole would not be party to such a policy It would be much better that this matter should be inquired into by an independent committee rather than by a department of the Ministry or the Treasury, because they were busy with other matters and had not the time to consider any of these questions with the quietness and calmness which they required The problem was not at all simple, because it was very difficult to find any convenient yardstick which would cover all the various types of hospital in the country Quite obviously, a teaching hospital in London would require more money proportionately to its patients than would some small cottage hospital in the country He was pleased to see that the Ministry had requested the Nuffield Provincial Hospitals Trust and the King Edward's Hospital Fund for London to make an inquiry into hospital costing But he rather doubted whether that inquiry would provide the final answer to the question, because he did not think it would take into consideration the differences in the running of the different types of hospital

It should be possible to arrive at the cost of inpatient treatment and outpatient treatment in the various types of hospital, and to pay each hospital a capitation fee Such a system would ensure that hospitals would try to achieve a reasonably quick turnover of beds thus reducing the waiting-lists Block grants were a good way of financing hospitals because they were subject to a five-year revision The system by which certain consultants on the staffs of hospitals were paid merit awards could affect the running of the hospital If some doctor was granted a merit award that sum became an additional burden on the maintenance charges for the period that he remained with the hospital The money required to make up that sum was taken from the hospital. It was very largely a paper transaction from the Treasury point of view, but from the hospital point of view it might be a serious cut

Lord SHEPHERD, for the Government, said that, except for one or two modifications, the system of estimating the costs of the hospital services was the same today as it had been from the start of the scheme There were few instances in the country, public or otherwise, where better arrangements were in force for governing finances If estimating was much more strictly dealt with today than it was a year ago that was not because of any change of policy on the part of the Government or the Minister, but because of a change of international circumstances which made it necessary to rearm The Minister looked upon the hospital service as a developing institution and likely to call upon Parliament for greatly increased grants in the next few years unless rearmament rendered such development out of the question. Inevitably, normal developments would cost a great deal of money because of increased prices All the management committees and regional boards were equally anxious that their hospitals should be developed, and for that purpose they would require money from the Government The most effective way in which applications could be made was by enabling them to put through estimates upon the basis of whether they could make out their case to the Minister Merely to get rid of these estimates and bring in block grants would not reduce the claims of the hospital services The working of a priority system would be impossible were it merely a case of a block grant being applied for It could be properly carried out only when full estimates were placed before the authorities who had to give the decision The unspent balances which might exist at the end of a year were not cash If a hospital authority had not exhausted its authority to spend and a balance remained, it merely lapsed This question of spending balances towards the end of a year had to be determined not by principle but according to the circumstances of the time A case had not been made out for the appointment of a committee of inquiry Hospital accounts were investigated by the Public Accounts Committee and the Estimates Committee The latter was giving special attention this year to the hospital service, and evidence would be given before it by officers of the Ministry, representatives of two regional boards, three management committees, the Royal College of Surgeons and the Royal

---

[1] Passe E R G Seymour J S *Brit med J* 1948 ii 812 Passe E R G Paper read at International Congress of Otorhinolaryngology London 1949 (in the press)

College of Physicians, King Edward's Hospital Fund, Nuffield Provincial Hospitals Trust, and the British Medical Association The Central Health Services Council, whose report in 1950 had just been published, had also dealt with hospital administration Some investigation of costing standards was being made, and departmental accounts on the basis of the circumstances of individual hospitals would be prepared this year for 108 hospitals of widely differing types, controlled by four regional boards and nine management committees The results of these inquiries should be awaited, and if there was then found to be need for further inquiry the Minister would be prepared to give consideration to the claim

Lord WEBB-JOHNSON said that no one could enter a hospital without seeing a change in the number of officials operating it not directly dealing with patients but with administration. Yet there was less work to be done on the administrative side because the administrative staff of the voluntary hospitals had to raise the money and to assess the income of patients He often wondered whether more advantage should be taken now of voluntary service An overhaul of administration and financial control was urgently needed, because this was not merely a matter of money but a matter of service Every pound wasted on administration was taken away from the patient, just as every bit of hospital accommodation taken up by management committees was lost to the treatment of patients A serious result of the high cost of hospital beds arose from the fact that the charges in private wings were based on the general hospital costs, which were so high that people who were prepared to pay for their treatment could not afford to do so It was not only to the disadvantage of the patients but also to the disadvantage of the reputation of British medicine when those distinguished colleagues who came to visit us from abroad found that patients who were willing to pay could not get into the hospitals

Lord DOWDING said that one basic defect in the organisation was the large number of hospital groups which a regional board had to administer The number was entirely beyond their capacity

Lord HADEN-GUEST, Lord-in-Waiting, said that it gave a wrong impression if a hospital service were considered as if it were the main feature of the National Health Service, although it was an extremely important one In the bad old days there was no hospital centralisation, and sometimes very little hospital control, the grotesque over-expenditure and bad conditions in many hospitals were well known Now that matters were getting on to a more definite and formal basis they had their own special problems, but these could be solved by common sense and the application of business principles It was less than three years since the National Health Service came into existence, and there had been built up in that time a service which had already produced very remarkable results in the health conditions of the country Whereas under the panel system there were 20,000,000 people entitled to receive medical aid without actual cash payment, under the National Health Service there were 43,000,000 Health was improving to an extent which was having at present a marked effect on the national physique and expectation of life That was worth paying for The consultants who before the National Health Service came into existence were largely concentrated in the large towns were now spread over the regions There was a good deal of room for improvement in methods of administration, and he thought that some of the costs could certainly be brought down This year there had been a reduction in the total cases of tuberculosis notified The work which the National Health Service was doing was worth every penny we were paying —and a good deal more At the moment it would be a mistake to set up a special committee

The motion for papers was by leave withdrawn

QUESTION TIME

Care of the Chronic Sick

Mr G C TOUCHE asked the Minister of Health if he was aware that the South West Metropolitan Regional Hospital Board had refused an offer from the Jewish Blind Society to take care of a number of chronically ill Jewish blind patients at the Jewish Home for the Blind, Rokefield, Westcott, at an all in figure of £5 per person a week on the ground that the board had not the money available, and if he would make special arrangements for this offer to be accepted in view of the fact that the cost to the regional board was less than the full maintenance of these patients in other hospitals —Mr MARQUAND replied I regret that the board cannot at present add to its existing contracts for beds in private institutions

Commander A H P NOBLE asked the Minister, in view of the fact that on Dec 31, 1950, there were 1324 patients on the waiting list for chronic sick beds in National Health Service hospitals in the county of London, what arrangements he was making to provide alternative accommodation to the 60 beds no longer available in St Luke's Hospital owing to transfer of certain wards to the Chelsea Hospital for Women for pathological laboratory work, and when this alternative accommodation would be available —Mr MARQUAND replied Alternative arrangements are being considered but I cannot make any further statement at present

Tuberculosis Treatment in Swiss Sanatoria

Brigadier FRANK MEDLICOTT asked the Minister if, in view of the fact that 10,000 people suffering from tuberculosis were awaiting admission to hospital in Great Britain, he could arrange with the hospital authorities in Switzerland a considerable increase beyond the 130 beds so far promised for patients from the United Kingdom —Mr MARQUAND replied I regret that this is not practicable

Waiting for Hearing-aids

In answer to a question Mr MARQUAND stated that on April 30 the waiting list for hearing aids stood at 112,365.

Training for Uneducable Children

Mrs E M. BRADDOCK asked the Minister what was the number of uneducable children who were not receiving any form of education, and what provision was being made to give them the specialised tuition they required —Mr MARQUAND replied On Jan 1, 1950, 13,680 mental defectives under the age of sixteen were in the care of local health authorities Of these 3600 were receiving some form of training That number has probably since increased by about 30% as the services are being progressively developed In addition, there are 6424 mental defectives under the age of sixteen in institutional care where, of course, they are receiving training

Complaint of Medical Negligence

Lord JOHN HOPE asked the Secretary of State for Scotland whether he would order an inquiry into the complaint by Miss Elizabeth Jessop of negligence against the medical authorities, particulars of which had already been sent to him —Mr H McNEIL replied that the local executive council's medical services committee had decided that Miss Jessop's complaint could not be further considered under the relative regulations, and he had no power to overturn such a decision

Lord JOHN HOPE Is not the right hon gentleman aware—I am sure he is, because I told him the whole story—that this lady after a bad motor smash, had only her skull X rayed? If they had X rayed her neck she would have been spared many months of pain and ill health It was only when that had been discovered that she made this complaint, and does he not think that on prima facie grounds this case ought to be looked into?—Mr McNEIL I have looked into it and I agree that the lady in question suffered greatly I am also aware that a whole range of experts on the subject missed this particular piece of diagnosis But I cannot set aside the regulations, nor do I think the hon gentleman would ask me to do so on reflection

Lord JOHN HOPE Has the right hon gentleman no power at all over these people? What happens about a case of suppression? Has he no ultimate jurisdiction to order an inquiry into it?—Mr McNEIL Certain remedies are available to the patient, but the question of suppression is quite a different matter from the action I am being asked to take here, which is to overturn a decision

Radiologists in Malaya

Air Commodore A V HARVEY asked the Colonial Secretary how many vacancies there were in Malaya for radiologists, and what steps he was taking to recruit them —Mr I F COOK replied that there were two which had been advertised in the medical press and brought to the attention of any doctor with radiological interests and experience who inquired about s in the Colonial Service Air Commodore HARVEY then . he had heard there were seven pieces of equipment at h and not even a part-time radiologist —Mr COOK eed to look into the matter

Special Diets Advisory Committee

n answer to a question Mr MAURICE WEBB, the Minister Food, stated that on all matters concerning extra rations l supplies of controlled foods for invalids and persons on cial diets he was advised by the Food Rationing (Special ets) Advisory Committee of the Medical Research Council e members of the committee were Dr H P Himsworth, C.P (chairman), Prof L S P Davidson, F.R C.P, Sir ancis Fraser, F.R C P, Lord Horder, F.R C.P, Dr R D wrence, F R C.P, Prof R A McCance, F.R C.P, F.R S, Norman Smith, F.R C P, Sir James Spence, F.R C.P, and of M. L Rosenheim F R C.P (secretary)

Obituary

ROBERT WILLIAM BASIL HALL

K.C.B , O B E , M R C S

Surgeon Vice-Admiral Sir Basil Hall, whose death we have already announced, was medical director-general of the Royal Navy and honorary physician to the King from 1934 to 1937

Hall came of a naval family and background He was born in 1876, the son of Robert Hall, R N , and he was educated at Portsmouth Grammar School In 1900 he qualified at Guy's Hospital and lost no time in joining the medical branch of the Navy Here his reputation for ability and conscientiousness quickly grew, and in 1913, while serving in H M S *Active*, he received the thanks of the Scottish Office for his work during an outbreak of influenza at St Kilda

During the first world war he served in the cruiser *Lowestoft*, which took part in the Dogger Bank action Hall had always shown special interest in the physiological problems arising in under-water craft, and in 1917 he was appointed senior medical officer of the submarine service His experience with this branch is lucidly set out in his *Handbook for Medical Officers of the Submarine Service* which was published in 1920 The same year he became an assistant to the medical director-general of the Navy Two years later he was awarded the Gilbert Blane medal in recognition of his zeal and professional ability, and in 1924 he was appointed O B E From 1926 to 1929 he was deputy D M D G , and in 1930 he was appointed C B and given charge of the R N hospital at Plymouth, where he remained till he was appointed director general in 1934 In 1936 he was promoted K C.B

After he retired from the Navy in 1937 he acted for two years as director of medical services to the International Council for Non-Intervention in Spain During the late war he proved an able chairman of the National Service medical board at Guildford

He married Miss Gertrude Goldsmith in 1906 She died in 1948, and in 1950 he married Dorothy, widow of Rear-Admiral (S) Cyril Capner Sir Basil died at Haslemere on May 10

MORTIMER PHILIP REDDINGTON

M B N Z F R C S M R C O G

Mr Mortimer Reddington, who died in London on May 25, at the age of 51, was born in New Zealand , and he graduated M B at Otago in 1922

In 1926 he came to this country and in resident posts at the Jessop Hospital in Sheffield and at the Royal Waterloo Hospital and the Grosvenor Hospital in London, he gained varied and practical experience in gynæcology and obstetrics In 1933 he took the F R C S and three years later the M R C O G Senior appointments in his specialty quickly followed , he was appointed to the staffs of the Woolwich Memorial Hospital, Royal Hospital, Richmond, and Joyce Green Hospital, and six years ago he also became consultant gynæcological surgeon to Queen Mary's Hospital, Sidcup From 1932 to 1940 he served as a surgeon lieutenant commander in the R N V R and he was for a time a consultant gynæcologist to the Admiralty His published works included papers on *hysterectomy and postpartum hæmorrhage*

C E writes "Reddington could not bear fools or slow-moving people gladly, for drive and brilliant activity were the dominant forces in his make-up But 'Rastus,' as his friends called him, was beloved by those that knew him well, and respected by those who appreciate high standards in surgical procedure Apart from professional life he had many interests , in his earlier years he played rugger for Middlesex Hospital, and latterly he took an active interest in royal tennis, often playing at Lord's and Hampton Court he was also a member of the M C C and St George's Hill Golf Club Not many of his friends realised his love for poetry , he composed many poems and a play in blank verse For the past year he had fought a losing battle with ill health, but he died unexpectedly after a period of convalescence "

Mr Reddington leaves a widow and three sons, two of whom are medical students and one an officer in the Regular Army

JOHN GRAHAM MARTIN

M D Lpool

By the death of Dr Graham Martin, at the age of 76, Liverpool has lost one of its best known and most trusted practitioners, and the country a great patriot

Graham Martin qualified in 1896, and, after holding appointments as resident medical officer, commenced what was to prove to be his constant devotion to national service by volunteering as a civilian surgeon for service in the South African war Whilst there he was, for a short time, a prisoner-of-war in the hands of the Boers He received the South African medal with four clasps No doubt inspired by this experience, he joined the Volunteers immediately on his return to Liverpool and was appointed surgeon lieutenant to the 2nd V B , the King's Liverpool Regiment When the Territorial Army superseded the Volunteers this battalion was renamed the 6th Battalion the King's Liverpool Regiment—the Liverpool Rifles—a battalion of the highest standing and repute in the city On the outbreak of the first world war he went to France with the rank of major

Those who served with him at that time remember with special gratitude his work during the first German gas attack on Ypres His was the only regimental aid post actually in Ypres and was situated in the old casemates He gave assistance to soldiers and civilians alike, and undoubtedly saved many lives Whilst, doubtless, he would have wished to continue service with his regiment his abilities were recognised and he was called upon to become first acting D A.D.M.S 55th Division and then D.A D M.S 5th Division until, in February, 1917, he was appointed to command the 58th C C.S After the war, when the Territorial Army was re formed he was appointed to command the 2nd (West Lancs) Field Ambulance, but in a very few months he became A.D M S of the 55th (West Lancs) Division In this appointment he did a tremendous amount of hard work re forming the R A M C units of the division His period of tenure of the appointment was extended more than once so that he held it for a total of eight years, finally retiring in December, 1928 He had been awarded the T D , and in 1927 he was appointed K H P The esteem and affection in which he was held by his brother officers was reflected in his appointment in 1930 as honorary colonel of the R A M C units of the 55th (West Lancs) Division

The details of his voluntary military service give measurable evidence of the devotion and worth of his work in that sphere, but there is no similar means of recording all that he achieved as a family doctor He was indeed the trusted and beloved adviser of very many His gift for friendship, his keen sense of humour, and his warmth of heart endeared him to all who came in contact with him His patients and their relatives have good cause to recall with gratitude his close attention to all the details of medical care His qualities were recognised by his colleagues who elected him to the council of the Liverpool Medical Institution for two periods, to the vice presidency in 1929, and to life membership in 1946

He died on May 18, and leaves a widow and only son, Captain H N G Graham Martin A A G

THE nucleic acids are essential constituents of living matter. Two forms of the acid are known to be present in all nucleated cells, and one or other form (in rare instances both) in viruses and bacteriophages. They are invariably found in combination with the various proteins of the cell.

In normal animal and plant cells deoxyribonucleic acid (D.N.A.) is located entirely within the nucleus, whereas ribonucleic acid (R.N.A.) is concentrated more particularly in the cytoplasm and in the nucleoli. R.N.A. is particularly abundant in the cells of growing tissues or of tissues showing high metabolic activity—e.g., in the production of protein secretions.

Some idea of the metabolic activity of the nucleic acids may be obtained by measuring their rate of renewal in the cell by techniques involving isotopes of phosphorus or of nitrogen. In a tissue such as the normal liver, in which the cells are not dividing rapidly although they are metabolically active, the turnover of D.N.A., as measured with P^{32} or N^{15}, is very low in comparison with that of R.N.A. (Davidson 1947, Furst et al. 1950). On the other hand, when such a tissue regenerates after injury, as rat liver after partial hepatectomy, the turnover of D.N.A. is very greatly increased and approaches that of R.N.A. This state of affairs is found in embryonic tissues and in such rapidly growing tissues as bone marrow and the abnormally proliferating leukæmic and malignant tissues (Hevesy 1948).

Ribonucleic Acid and Protein Synthesis

Owing largely to the work of the Caspersson (1947, 1950) school, a connection between nucleic acid metabolism and protein synthesis is widely postulated, both in the course of tissue growth by mitotic division of cells and in the elaboration of special proteins during differentiation and secretion. The exact way in which the nucleic acids take part in such processes is still unknown, but several mechanisms have been suggested (for discussion see Brachet 1947 and Davidson 1950).

Value of Quantitative Studies

The study of cellular nucleic acids and proteins is of value in both the practical and the theoretical approach to quantitative cellular pathology. In the familiar procedures for fixing and staining cells in tissue sections, smears, &c., the cellular constituents chiefly involved are the nucleic acids and proteins. The absolute amounts of these constituents per cell can be determined either by cytochemical techniques applied to the individual cell or by microchemical techniques applied to aggregates of cells. With mixed or growing tissues and cell populations the values obtained by microchemical techniques may require expression as averages, unless special methods are used. Such data may lead to an understanding of cellular activity.

Methods of Quantitative Study

The pioneer application of optical methods to the quantitative study of single cells is due to Caspersson and his colleagues, who have concentrated largely on the ultraviolet and near visible spectral regions, and have made abundant use of the fact that nucleic acids show an intense and specific absorption of ultraviolet light at 2600 Å (Caspersson 1950). The reflecting microscope (Barer 1949) has been used for a similar purpose (Barer et al. 1950). By these methods large numbers of single cells in cytochemical preparations can be analysed, and the distribution of certain constituents which possess clear cut properties of light absorption in various parts of the visible, ultraviolet, or infra red spectrum may be expressed quantitatively. A limitation is the difficulty of controlling completely all the physical characteristics of the systems under investigation (Commoner 1949, 1950, Pollister and Swift 1950).

The alternative method is to determine microchemically the amounts of nucleic acids in tissue samples in which the cells can be counted. From the number of cells it is possible to calculate the average content per cell or nucleus.

Constant Value of Cellular D.N.A.

The work of Boivin et al. (1948), Vendrely and Vendrely (1948, 1949), and Mirsky and Ris (1949) on the analysis of nuclei isolated from various vertebrate genera and species suggests a very constant value for the amount of D.N.A. per nucleus for the different tissues of any one species, though considerable variation may occur between species. Each of the haploid spermatozoa contains about half the amount of D.N.A. present in a somatic nucleus. This fact has obvious implications in genetics, and is evidence that the genes are deoxyribonucleoprotein units.

An important practical implication is that by determining the amount of D.N.A. in a sample of tissue, one can calculate the number of cells present and consequently the amount, per cell, of any other substance of which the total amount in the sample is known (Davidson and Leslie 1950a and b). It is, however, of vital importance to know the possible variations in the amount of D.N.A., per nucleus, of any given tissue in different physiological and pathological conditions.

Present Work

Our investigations have been largely concerned with human bone marrow and blood leucocytes in health and disease and with spermatozoa, because suspensions of these tissues can be made in which the cells are sufficiently evenly distributed to allow them to be counted as a basis for determination of the average amount of D.N.A. and R.N.A. per cell.

METHODS

Bone marrow.—Small samples of 0·2–0·3 ml. of mixed marrow and blood were aspirated from the sternum of healthy volunteers and from patients with various blood disorders. The sample, of known weight, was evenly suspended in heparinised 0·85% sodium chloride solution, and a small aliquot was removed for dilution and enumeration of nucleated cells in the Neubauer hæmocytometer chamber. The remainder was used for chemical micro determination of deoxyribonucleic acid phosphorus (D.N.A.P.) and of ribonucleic acid phosphorus (R.N.A.P.). As in previous work on marrow tissue (Davidson et al. 1948), the acids were separated by the Schmidt and Thannhauser (1945) method, and phosphorus determined by Davidson and Waymouth's (1943) modification of the Berenblum and Chain (1938) method.

Blood Leucocytes.—Samples were handled similarly, but often the leucocytes were separated from the erythrocytes and plasma with the aid of bovine fibrinogen (Minor and Burnett 1948).

Reticulocytes.—Blood samples rich in reticulocytes were examined from two cases of hæmolytic anæmia. All the ribonucleoprotein containing reticular material was retained in the stromal precipitate separated at pH 5·6

Diary of the Week

JUNE 10 TO 16

Monday, 11th

Royal Society of Medicine and British Medical Association
2 30 P M (1 Wimpole Street, W 1) *Festival programme* Ophthalmology

Tuesday, 12th

Royal College of Surgeons Lincoln's Inn Fields, W C 2
5 P M Prof J M Yoffey The Lymphatic System—a film (Arris and Gale lecture)

Royal Society of Medicine and British Medical Association
10 30 A M *Festival programme* Plastic Surgery

West End Hospital for Nervous Diseases, 40, Marylebone Lane W 1
2 30 P M Dr Douglas Gordon Radiological Techniques

West London Hospital Medical School
8 30 P M (11 Chandos Street, W 1) Dr Leonard Colebrook F R S Outstanding Problems of Burns and Scalds (Alex Simpson Smith lecture)

Institute of Dermatology, St John's Hospital Lisle Street W C 2
5 P M Dr D I Williams Sex Hormones in Dermatology

Institute of Neurology, National Hospital, Queen Square, W C 1
5 P M Prof Torsten Sjögren (Stockholm) Hereditary Neurological Diseases Associated with Certain Eye Diseases

Wednesday, 13th

University of London
5 30 P.M (University College Gower Street W C 1) Dr G G Simpson Origin and Early Evolution of the Primates

Institute of Dermatology
5 P M Dr R W Riddell Medical Mycology—Trichophyton Infections

Institute of Psychiatry, Maudsley Hospital Denmark Hill, S E 5
3 P M Professor Sjögren Heredity of Pick s Disease and other Presenile Conditions

Thursday, 14th

Royal College of Physicians, Pall Mall East, S W 1
5 P M. Dr W E Lloyd Pulmonary Tuberculosis in Young Adults (Mitchell lecture)

Royal College of Surgeons
3 P M Mr Harvey Jackson Surgery of Orbital Tumours
5 P M Dr Henry Cave, F A C.S Emergency Surgery of the Abdomen

Royal Society of Medicine and British Medical Association
2 P M *Festival programme* The Central Nervous System

St George's Hospital Medical School, Hyde Park Corner, S W 1
4 30 P M. Sir Paul Mallinson Psychiatry lecture demonstration

Institute of Dermatology
5 P M Dr S C Gold Systemic Lupus Erythematosus

Chadwick Lecture
4 P.M. (Chelsea Physic Garden, Swan Walk S W 3) Prof T A Bennet Clark PH D F R S Capacity of Vegetation to Support Human Population

University of Durham
5 15 P.M (Royal Victoria Infirmary Newcastle upon Tyne) Prof. Warren H Cole (Chicago) Carcinoma of the Stomach

Honyman Gillespie Lecture
5 P.M (University New Buildings Teviot Place, Edinburgh Dr John Macaskill Retinal Changes in Hypertension

Friday, 15th

Royal Society of Medicine and British Medical Association

* Amended notice

Births, Marriages, and Deaths

BIRTHS

Bowers —On May 31 at Folkestone the wife of Dr V H Bowers —a daughter

Chamberlain —On May 27 in Leeds the wife of Mr Digby Chamberlain F R C.S —a son

Langdon Down —On May 20 in London the wife of Dr Norman Langdon Down—twin daughters the elder of whom survived only three days

Stringer.—On June 1 in London the wife of Mr Paul Stringer F R C.S —a daughter

MARRIAGES

Garratt—Kiln —On May 26, at Forest Row Sussex Cecil Douglas Garratt, M R C P , to Ann Kiln M B

DEATHS

Dickson —On May 29 at Aspley Guise Beds, Arthur Norman Dickson M C M B Camb colonel I M S retd aged 70

Hunter —On May 17 at Newcastle upon Tyne, Kenneth Downie Hunter M B Durh

Irving —On May 28 at Totland Bay I o W William Irving, M D Camb M R C O G , formerly of Christchurch New Zealand aged 81

Norton —On May 31, at Bury St Edmunds Edgar Lionel Robert Norton M D Lond formerly of Winnipeg

Young —On May 31 at Twyford, Berks Frederic Charles Young M B Camb but worse on coughing It was keeping her awake at night

There was nothing relevant in her history She was a diabetic She had previously been investigated elsewhere, and a barium meal, a cholecystogram, and a barium enema had all been negative

On examination a small area of localised tenderness was found about 3 in to the left of, and 1 in. above the umbilicus On palpation there seemed to be a small nodule at the site of the tenderness

Because the tenderness was so localised it was decided to try the effect of local anæsthesia. On Sept 3, Proctocaine 10 ml. was injected into the tender and painful area The tenderness and pain immediately disappeared For the next five nights for the first time for five months the patient was able to sleep at night, and had no pain. Then the pain returned and again the same site was tender Again a small nodule seemed to be palpable

On Sept 12, 1950 under general anæsthesia, a transverse incision was made over the tender area and was deepened through the subcutaneous fat The rectus sheath and the external oblique aponeurosis were cleared A small protrusion of fat, about 0·5 × 1 cm. was seen emerging through the semilunar line Closely related to the fat lobule was a small vessel By careful dissection it was possible to demonstrate clearly that the fat lobule was a fatty hernia through a small defect in the linea semilunaris and that the vessel also emerged through this small defect Deeply the fatty hernia was dragging up a small pouch of peritoneum. The peritoneum was separated from the deep aspect of the aponeurosis of the transverse abdominis muscle and from the edges of the defect The fatty lobule was excised. The defect in the linea semilunaris was closed with mattress sutures, and the wound closed

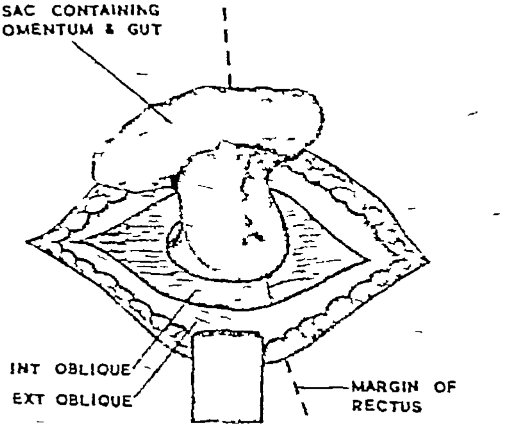

Fig 2—Hernial sac emerging from linea semilunaris at operation on case 3

From the time of operation the patient was free from pain and when last seen in Feburary, 1951, she was a much happier woman

ANATOMY

The literature shows some difference of opinion as to what constitutes Spigel s line

Watson (1938) states that the linea semilunaris is formed by the aponeurosis of the internal oblique muscle at its point of division to enclose the rectus muscle He describes it as extending from the ninth costal cartilage to the pubic spine, and identifies it with the lateral border of the rectus abdominis muscle River (1942) on the other hand states that it is the line of transition between the muscle bundles and aponeurosis of the transversus abdominis muscle Its convexity is outward, and it lies decreasingly distant from the midline as it is followed from the umbilicus. River says it does not coincide with the line of transition in the internal oblique muscle, which, unless extreme muscular aplasia exists, follows the rectus muscle closely

It is certain, however, that the relationship of the lines of transition of the transversus and internal oblique muscles varies in different patients Where the two lines coincide, with the result that the aponeuroses fuse lateral to the rectus muscle, it seems likely that herniation through any defect in this layer of aponeurosis would be easier

ÆTIOLOGY

In case 4 the small fatty hernia was clearly associated with a vascular bundle, and had escaped through a vascular foramen This view of the causation of these hernias was put forward by Cooper, Makrocki, Reigner, and others (cited by Watson 1938) Barthelemey and Molière are quoted by Watson as stating that the cause of these hernias was the arrangement of the layers of aponeurosis in relation to the rectus muscle In some cases the fascia is loosely attached to the muscle, and may give rise to a diverticulum or pocket opening downward or inward into which a hernia may be pushed during a sudden strain when the body is bent forward (Watson 1938) River (1942) describes numerous irregular slit like defects up to 3 or 4 mm long where the aponeurosis of the transversus abdominis muscle passes forward and fuses with that of the internal oblique muscle

SYMPTOMS AND SIGNS

A patient with a Spigelian hernia may present complaining of pain or of a lump, or of both pain and a lump It is the patient complaining only of pain, with no visible or even palpable lump, who causes the greatest difficulty in diagnosis, as in case 4.

A Spigelian hernia in its earliest form is simply a protrusion of retroperitoneal fat through the semilunar line—a condition similar to fatty hernia of the linea alba The small fatty lump may be palpable, or the hernia may be interstitial, penetrating the aponeurosis of the transversus abdominis muscle only, and spreading out in the abdominal wall beneath the internal oblique muscle In an early stage the patient complains of pain localised in the abdominal wall and aggravated by coughing or straining There may also be some vague symptoms of dyspepsia, probably related to the pull exerted by the fatty hernia on the parietal peritoneum. In this early stage the only physical sign may be a localised area of tenderness, which can be banished by the injection of a local anæsthetic If the fatty lump is large enough or the patient not obese, a small mass may be palpable

As the condition progresses, so the symptoms and signs become more prominent, and are similar to those of external hernias elsewhere in the body

TREATMENT

Surgical repair is required for these hernias because of pain and the very real danger of strangulation Cases with symptoms of intestinal obstruction following incarceration with impending strangulation have been described by River (1942) Bryant (1947), Mason and Ruge (1948) and Holloway (1922) The hernial sac should be removed if there is one, and the defect in the abdominal wall is best repaired by the Mayo overlap method with mattress sutures

One advantage of knowing the D N A content of the nucleus is that a determination of D N A as well as other chemical constituents in a sample of tissue enables us to calculate the amount of such constituents in each cell In this way the amount of lipid phosphorus, protein, nitrogen, and R N A P in the kidney and prostate cells have been determined This procedure opens up a new approach in the study of cellular pathology, since it is now possible to express the composition of a tissue in terms of the average composition per cell, and to compare the results of chemical estimations with those of microscopy The results of such a comparison are particularly interesting in marrow from cases of megaloblastic anæmia, in which the D N A content of the nucleus is significantly raised, and a greatly increased R N A content of the cell explains the very pronounced basophilia of the cytoplasm of the younger megaloblasts

Our thanks are due to many colleagues for their interest in this work, and for facilities to study patients, and to Miss Margaret Meikle for valuable technical assistance One of us (J N D) was in receipt of an expenses grant from the Medical Research Council

SPIGELIAN HERNIA

HERNIA THROUGH THE LINEA SEMILUNARIS

REPORT OF FOUR CASES

SIR CECIL WAKELEY
K B E, C B, M Ch, D Sc, F.R C S
SENIOR SURGEON AND TEACHER OF CLINICAL SURGERY, KING'S COLLEGE HOSPITAL, LONDON, CONSULTING SURGEON TO THE ROYAL NAVY

PETER CHILDS
M.A, D M, M.Ch Oxfd, F R C S
SURGEON, SOUTH DEVON AND EAST CORNWALL HOSPITAL, PLYMOUTH

A SPIGELIAN hernia is one of the less common forms of hernia It is a herniation through the semilunar, or Spigel's line (fig 1) River (1942) found that only 116 cases of true spontaneous lateral ventral hernia through Spigel's line had been reported up to 1942 In this country cases have been reported by Paul and Hill (1943), Reid (1949), and Watson and Scotter (1951) We report here four more cases

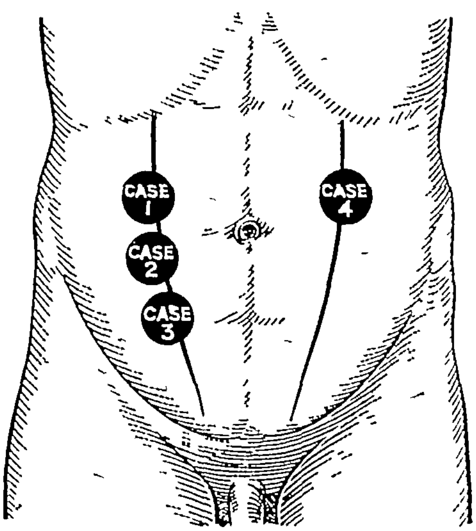

Fig 1—Sites of Spigelian hernias in cases 1–4.

CASE RECORDS

Case 1 —A naval stoker, aged 50, was admitted to hospital on May 5, 1916, complaining of a diffuse lump on the right side of his umbilicus The lump was about the size of a cricket ball It was painful, dull on percussion, and non translucent. So far as the patient knew, it had been present for two years and was getting larger There was no history of trauma The patient had had one or two attacks of vomiting

On July 6, 1916, under general anæsthesia, the lump was explored through a transverse incision A hernial sac containing a large mass of omentum and part of the transverse colon was exposed The sac of peritoneum emerged from a rounded hole in the right linea semilunaris just above the level of the umbilicus The omentum was resected and the transverse colon returned to the abdomen. The sac was excised and the hernial defect closed with three mattress sutures

Recovery was uneventful When the patient was seen again in January, 1919, there was no sign of recurrence

Case 2 —A fat married woman aged 55, was admitted to hospital on March 10, 1922, complaining of a swelling situated to the right of her umbilicus The lump had appeared some eighteen months previously, after the birth of her sixth child The swelling was diffuse and about the size of a billiard ball It was dull on percussion and painful on pressure

On March 11, 1922, under local anæsthesia a transverse incision was made over the swelling, and a hernial sac exposed emerging through the linea semilunaris The sac was incised and found to contain some omentum and the cæcum The omentum was excised and the cæcum returned to the abdomen. The hernial sac was transfixed, ligatured, and excised, and the defect in the abdominal wall was closed with two mattress sutures

Recovery was uneventful

Case 3 —A married woman, aged 62, was admitted to hospital on April 3, 1930, complaining of a lump on the right side of her abdomen just below and lateral to the umbilicus (fig 1) The lump was about the size of a hen's egg and disappeared when the patient lay down

On April 4, 1930, under general anæsthesia, a transverse incision was made over the lump and a hernial sac exposed (fig 2) The sac was found to contain omentum and the cæcum The omentum was excised, and the cæcum returned to the abdominal cavity The hernial ring was closed with mattress sutures

Recovery was uneventful

Case 4 —A married woman aged 53, was first seen in August, 1950, with four months' history of pain on the left side of her abdomen The pain was becoming more pronounced The patient described the sensation as being as though " there's something there that shouldn't be and it s sticking into me all the time The pain was constant,

TABLE III—MORTALITY IN CASES WHERE BLEEDING RECURS OR STARTS AFTER ADMISSION TO HOSPITAL OR THERE ARE OTHER FACTORS INCREASING THE MORTALITY, AND THE SIGNIFICANCE OF THE TYPE OF BLEEDING

Type of bleeding	Whole series		Perforation and/or severe pain and/or bleeding starting in hospital			
			Incidence		Fatal cases	
	No	%	No	%	No	%
Hæmatemesis } recurring or starting in hospital	68	22	18	40	11	61
Melæna } recurring or starting in hospital	26	8	12	27	3	25
Total	94	30	30	67	14	47
No hæmorrhage after admission	221	70	15	33	1	7
Total	315	100	45	100	15	33

Nearly all the operations had been done a considerable time before.

Table II shows the patients listed under only one symptom, even though they had others, and the symptoms take precedence in the order shown from top to bottom—e g, a patient with pain and cachexia is listed only under pain

The age incidence is not shown but is of the usual significance

The first four factors listed in table I increased the mortality, and must be taken to mean that the patient had a severe, penetrating, and usually chronic ulcer This accords with the findings of other workers (Allen and Benedict 1933, Baker 1947, Finsterer 1947, Gordon-Taylor 1946, Avery Jones 1947)

In the present series the factors increasing the mortality may be reduced to severe pain and/or hæmorrhage starting in hospital (table II), in the presence of one or both of these factors the mortality from hæmatemesis after admission to hospital was about 60% (tables III and IV) In hospital the incidence of these factors in the presence of melæna is comparatively higher than in hæmatemesis, yet the mortality is considerably lower (table III), but the patients with melæna were on the average somewhat younger than those with hæmatemesis The group of 68 patients who had hæmatemesis in hospital, with a mortality of 31% (table IV), is divisible, by other easily recognisable signs (hæmorrhage starting in hospital and/or severe pain), into 16 with a mortality of 63% and 52 with a mortality of 21% (table IV)

14% had previously undergone operation for peptic ulcer, and the gross mortality among them was the same as that of the entire series Little interest seems to have been shown in this aspect Welch and Yunich (1940) had no deaths among their patients with bleeding peptic ulcer who had previously undergone gastro enterostomy

TABLE IV—MORTALITY FROM HÆMATEMESIS IN HOSPITAL COMBINED WITH OTHER SYMPTOMS

Hæmatemesis in hospital	No	Fatal cases	
		No	%
Entire series	68	21	31
Severe pain in hospital and/or bleeding starting in hospital	16	10	63
Other cases of hæmatemesis	52	11	21
Only one hæmatemesis	39	9	23
More than one hæmatemesis	29	12	41
History of manifest hæmorrhage *	28	8	29
No manifest hæmorrhage in the past	39	12	31

* Data lacking in the case of one death

The incidence of previous attacks of bleeding is very high, as Rischel (1936) and Hesser (1942) also found in their series Among the "relapsers" the mortality is lower, if anything, than among the patients bleeding for the first time Of 27 deaths 17 took place in connection with the first episode of hæmorrhage A similar finding has been reported by Christiansen (1935), Allen and Benedict (1933), Blackford and Allen (1942), Welch (1949), and Baker (1947), but not by Sullens et al. (1949)

It is clear from table V that the prognosis is the same, whether manifest bleeding has taken place once or three times or more, if only the present bleeding is in the form of hæmatemesis Every time a hæmorrhage takes place, the patient has the same chance—i e, that appropriate to his age group It will be seen from the table that the difference in the mortality among patients admitted to hospital during the first attack (17 out of 164) and those who have had one or several attacks before (10 out of 150), is due almost exclusively to a difference in mortality from hæmatemesis and from melæna alone

Conclusion

The mortality is increased in the presence of the following symptoms perforation, severe pain in hospital, hæmorrhage starting in hospital, stenosis, and cachexia No such increase is caused by previous operations for peptic ulcer (gastro enterostomy) or previous manifest bleeding

The combination of hæmatemesis in hospital with severe pain in hospital or with hæmorrhage starting in hospital entailed a mortality of 60%

TABLE V—MORTALITY RATE IN RELATION TO PREVIOUS ATTACKS OF HÆMORRHAGE

No of previous attacks of hæmorrhage	Mode or manifestation of hæmorrhage at present admission					
	Hæmatemesis before and/or after admission		Melæna only		Entire series	
	No of admis	Deaths *	No of admis	Deaths	No of admis.	Deaths
None	113	15 (*13%*)	51	2 (*4%*)	164	17 (*10%*)
Only one	43	5 (*12%*)	24	1 (*4%*)	67	6 (*9%*)
Two or more	39	4 (*10%*)	45	0	84	4 (*5%*)
Three or more	22	2 (*9%*)	30	0	52	2 (*4%*)
One or more	82	9 (*11%*)	68	1 (*2%*)	150	10 (*7%*)

* Data not available in one excluded case

This analysis illustrates how impossible it is to compare most mortality statistics, especially gross mortalities (Avery Jones 1947, Pedersen 1941, 1949)

CRITERIA OF OPERATION

Not all the results obtained by the present analysis are applicable directly to the criteria of operation The present analysis was based on the entire series, including patients who did not die from exsanguination and non-operable patients The criteria of operation, on the other hand, can be based only on operable patients with hæmorrhage after admission and, according to my previous investigations (Pedersen 1941, 1949), only on operable patients with hæmatemesis in hospital This reduces the material which can be used in assessing the criteria of operation from 68 with hæmatemesis in hospital of whom 21 died (table IV) to 50 of whom 9 died (For my estimation of the operability among the deceased and the survivors see *Pedersen 1949*)

As might be expected, the significance of the factors studied is restricted by their occurrence in relatively few of the deceased patients who had been operable Therefore, the entire analysis will not be repeated on the basis of the relevant material, but table VI illustrates the result of a study of a few factors in this material

CHOICE OF CONSERVATIVE OR SURGICAL TREATMENT IN BLEEDING PEPTIC ULCER*

JØRGEN PEDERSEN
M D Copenhagen
SENIOR ASSISTANT PHYSICIAN, MEDICAL DEPARTMENT B, FREDERIKSBERG HOSPITAL, COPENHAGEN

THE mortality attending gastric surgery has much decreased of late, and in a few hospitals the treatment of acute bleeding ulcer has therefore been modified, consisting now of surgical as well as conservative measures The great majority of cases are still treated conservatively in the acute phase , surgery is reserved for the relatively few in which the prognosis with medical treatment is regarded as poor

The introduction of this surgical treatment has led to renewed interest in the prognosis of bleeding peptic ulcer In a small group of patients who are elderly or have persisted or repeated bleeding the mortality is normally high (about 30%) Such patients are therefore potential subjects for surgery , but the final selection for operation is made according to more definite criteria

The time of operation is a key problem , for the operation mortality depends on how often or how long the patient has been in a state of shock It is important to detect at an early stage of the bleeding those cases which require operation, and to operate at once , and it is equally important not to operate in the acute phase on patients who will recover with conservative treatment

The surgical treatment can be divided into two types surgery after trial, and immediate surgery "Surgery after trial" means that conservative treatment (blood transfusion) has been tried to stop the bleeding, and that no operation is done unless conservative treatment has been unsuccessful "Immediate surgery" means that the patient undergoes operation as soon as possible after admission to hospital with massive hæmorrhage , here the amount of bleeding is the decisive factor Surgery after trial is advocated by Avery Jones (1947) and Dunphy and Hoerr (1948), and immediate surgery by Finsterer (1947), Tanner (1949a), and Stewart et al (1948)

TABLE I—PROGNOSTIC SIGNIFICANCE OF VARIOUS SYMPTOMS AND SIGNS

Symptoms and signs	Whole series (315 cases)		Fatal cases (28)		
	No	Incidence %	No	Incidence %	Mortality %
Perforation	2	1	1	4	50
Bleeding starting in hospital,	18	6	7	25	39
Severe pain in hospital	30	10	9	32	30
Stenosis and / or cachexia	27	9	6	21	22
Previous operation for peptic ulcer	44	14	4	14	9
Previous manifest hæmorrhage*	150	48	10	36	7

* Data lacking in 1 fatal case

I have previously proposed (Pedersen 1949) the following criteria for operation in cases of acute bleeding peptic ulcer (1) patients aged 50 or more, with a definite peptic ulcer, should be submitted to operation—in the absence of serious contra indications—if hæmatemesis occurs in hospital after admission , and (2) operation should be done as soon as possible after the first hæmatemesis in hospital

This proposal was the result of an analysis of the mortality of bleeding peptic ulcer treated conservatively in Copenhagen The series included 31 fatal cases, and 90–100% of the patients who, in my opinion, might have been saved by appropriate surgery did not die until one or several brisk hæmatemeses had occurred in hospital. Fatal cases showing melæna alone are rare (Pedersen 1941, 1949) and generally inoperable

In the present investigation I studied the prognostic significance of factors which had not been studied in my previous analysis (Pedersen 1949) to see whether the criteria for operation then suggested needed any alteration.

MATERIAL

The material consisted of the same series as before—i e , patients in medical department B (Prof E Meulengracht) of Bispebjerg Hospital, Copenhagen, from May 1, 1938, to May 1, 1948 It includes all the patients aged 40 or more who had manifest bleeding of at least 1 litre either as hæmatemesis or as melæna and showed signs of peptic ulcer either on radiography or at necropsy The group comprises 317 admissions for hæmorrhage in a total of 288 patients During the period under discussion 31 patients died in connection with bleeding peptic ulcer (found by the perusal of about 2500 necropsy records) and no less than 30 of these 31 patients were in the group selected for analysis , 1 was aged less than 40 and thus is not included in the series

TABLE II—ANALYSIS OF FACTORS (LISTED IN TABLE I) WHICH INCREASED THE MORTALITY

Symptoms and signs	Total no of cases	Fatal cases	
		No	%
Perforation	2	1	50
Severe pain in hospital (no perforation)	30	9	30
Bleeding starting in hospital (no perforation, no pain)	13	5	38
Stenosis and/or cachexia (admitted to hospital because of bleeding, no perforation no pain)	15	1	[illegible]
Total	60	16	27

TREATMENT

The treatment was conservative, according to Meulengracht's (1947) principle of early and liberal feeding, administration of ample fluid, and blood transfusion Transfusions were given more often during the latter part of the period than at the outset Only 1 patient was operated on

ANALYSIS

The analysis comprises only 315 hæmorrhages (28 fatal) , 2 patients died, from severe meningitis and from severe heart disease, without the hæmorrhage being manifest in life and so are excluded The following factors were studied (1) perforations , (2) hæmorrhage starting in hospital , (3) severe pain in hospital , (4) stenosis and/or cachexia , (5) operation for peptic ulcer , and (6) manifest hæmorrhage in the past (tables I–V)

In table I, if a patient has pyloric stenosis as well as pain he is included in both groups The two perforations listed were chronic, and there was no acute diffuse peritonitis "Bleeding starting in hospital" includes bleeding during ulcer management, "interval bleeding," and bleeding starting in another department (7 patients were transferred from a surgical department, and 1 from a psychiatric department) Patients who have had multiple operations are listed only once With partial gastrectomy taking precedence over gastroenterostomy, the latter over suture, and suture over other minor interventions, of the 44 patients listed 5 had had partial gastrectomy, 20 gastro enterostomy 7 simple suture, and 3 some other operation

TABLE III—MORTALITY IN CASES WHERE BLEEDING RECURS OR STARTS AFTER ADMISSION TO HOSPITAL OR THERE ARE OTHER FACTORS INCREASING THE MORTALITY, AND THE SIGNIFICANCE OF THE TYPE OF BLEEDING

Type of bleeding		Whole series		Perforation and/or severe pain and/or bleeding starting in hospital			
				Incidence		Fatal cases	
		No	%	No	%	No	%
Hæmatemesis	recurring or starting in hospital	68	22	18	40	11	61
Melæna	recurring or starting in hospital	26	8	12	27	3	25
Total		94	30	30	67	14	47
No hæmorrhage after admission		221	70	15	33	1	7
Total		315	100	45	100	15	33

Nearly all the operations had been done a considerable time before

Table II shows the patients listed under only one symptom, even though they had others, and the symptoms take precedence in the order shown from top to bottom—e g, a patient with pain and cachexia is listed only under pain

The age incidence is not shown but is of the usual significance

The first four factors listed in table I increased the mortality, and *must* be taken to mean that the patient had a severe, penetrating, and usually chronic ulcer This accords with the findings of other workers (Allen and Benedict 1933, Baker 1947, Finsterer 1947, Gordon-Taylor 1946, Avery Jones 1947)

In the present series the factors increasing the mortality may be reduced to severe pain and/or hæmorrhage starting in hospital (table II), in the presence of one or both of these factors the mortality from hæmatemesis after admission to hospital was about 60% (tables III and IV) In hospital the incidence of these factors in the presence of melæna is comparatively higher than in hæmatemesis, yet the mortality is considerably lower (table III), but the patients with melæna were on the average somewhat younger than those with hæmatemesis The group of 68 patients who had hæmatemesis in hospital, with a mortality of 31% (table IV), is divisible, by other easily recognisable signs (hæmorrhage starting in hospital and/or severe pain), into 16 with a mortality of 63% and 52 with a mortality of 21% (table IV)

14% had previously undergone operation for peptic ulcer and the gross mortality among them was the same as that of the entire series Little interest seems to have been shown in this aspect Welch and Yunich (1940) had no deaths among their patients with bleeding peptic ulcer who had previously undergone gastro-enterostomy

TABLE IV—MORTALITY FROM HÆMATEMESIS IN HOSPITAL COMBINED WITH OTHER SYMPTOMS

Hæmatemesis in hospital	No	Fatal cases	
		No	%
Entire series ..	68	21	31
Severe pain in hospital and/or bleeding starting in hospital	16	10	63
Other cases of hæmatemesis	52	11	21
Only one hæmatemesis	39	9	23
More than one hæmatemesis	29	12	41
History of manifest hæmorrhage *	28	8	29
No manifest hæmorrhage in the past	39	12	31

* Data lacking in the case of one death

The incidence of previous attacks of bleeding is very high, as Rischel (1936) and Hesser (1942) also found in their series Among the "relapsers" the mortality is lower, if anything, than among the patients bleeding for the first time Of 27 deaths 17 took place in connection with the first episode of hæmorrhage A similar finding has been reported by Christiansen (1935), Allen and Benedict (1933), Blackford and Allen (1942), Welch (1949), and Baker (1947), but not by Sullens et al (1949)

It is clear from table V that the prognosis is the same, whether manifest bleeding has taken place once or three times or more, if only the present bleeding is in the form of hæmatemesis Every time a hæmorrhage takes place, the patient has the same chance—i e, that appropriate to his age group It will be seen from the table that the difference in the mortality among patients admitted to hospital during the first attack (17 out of 164) and those who have had one or several attacks before (10 out of 150), is due almost exclusively to a difference in mortality from hæmatemesis and from melæna alone

Conclusion

The mortality is increased in the presence of the following symptoms perforation, severe pain in hospital, hæmorrhage starting in hospital, stenosis, and cachexia No such increase is caused by previous operations for peptic ulcer (gastro enterostomy) or previous manifest bleeding

The combination of hæmatemesis in hospital with severe pain in hospital or with hæmorrhage starting in hospital entailed a mortality of 60%

TABLE V—MORTALITY RATE IN RELATION TO PREVIOUS ATTACKS OF HÆMORRHAGE

No of previous attacks of hæmorrhage	Mode or manifestation of hæmorrhage at present admission					
	Hæmatemesis before and/or after admission		Melæna only		Entire series	
	No of admis	Deaths *	No of admis.	Deaths	No of admis.	Deaths
None	113	15 (*13%*)	51	2 (*4%*)	164	17 (*10%*)
Only one	43	5 (*12%*)	24	1 (*4%*)	67	6 (*9%*)
Two or more	39	4 (*10%*)	45	0	84	4 (*5%*)
Three or more	22	2 (*9%*)	30	0	52	2 (*4%*)
One or more	82	9 (*11%*)	68	1 (*3%*)	150	10 (*7%*)

* Data not available in one excluded case

This analysis illustrates how impossible it is to compare most mortality statistics, especially gross mortalities (Avery Jones 1947, Pedersen 1941, 1949)

CRITERIA OF OPERATION

Not all the results obtained by the present analysis are applicable directly to the criteria of operation The present analysis was based on the entire series, including patients who did not die from exsanguination and non operable patients The criteria of operation, on the other hand, can be based only on operable patients with hæmorrhage after admission and, according to my previous investigations (Pedersen 1941, 1949), only on operable patients with hæmatemesis in hospital This reduces the material which can be used in assessing the criteria of operation from 68 with hæmatemesis in hospital of whom 21 died (table IV) to 50 of whom 9 died. (For my estimation of the operability among the deceased and the survivors see Pedersen 1949)

As might be expected, the significance of the factors studied is restricted by their occurrence in relatively few of the deceased patients who had been operable Therefore, the entire analysis will not be repeated on the basis of the relevant material, but table VI illustrates the result of a study of a few factors in this material

CHOICE OF CONSERVATIVE OR SURGICAL TREATMENT IN BLEEDING PEPTIC ULCER*

JØRGEN PEDERSEN
M.D Copenhagen
SENIOR ASSISTANT PHYSICIAN, MEDICAL DEPARTMENT E,
FREDERIKSBERG HOSPITAL, COPENHAGEN

THE mortality attending gastric surgery has much decreased of late, and in a few hospitals the treatment of acute bleeding ulcer has therefore been modified, consisting now of surgical as well as conservative measures The great majority of cases are still treated conservatively in the acute phase , surgery is reserved for the relatively few in which the prognosis with medical treatment is regarded as poor

The introduction of this surgical treatment has led to renewed interest in the prognosis of bleeding peptic ulcer In a small group of patients who are elderly or have persisted or repeated bleeding the mortality is normally high (about 30%) Such patients are therefore potential subjects for surgery , but the final selection for operation is made according to more definite criteria

The time of operation is a key problem , for the operation mortality depends on how often or how long the patient has been in a state of shock It is important to detect at an early stage of the bleeding those cases which require operation, and to operate at once, and it is equally important not to operate in the acute phase on patients who will recover with conservative treatment

The surgical treatment can be divided into two types surgery after trial, and immediate surgery "Surgery after trial" means that conservative treatment (blood-transfusion) has been tried to stop the bleeding, and that no operation is done unless conservative treatment has been unsuccessful "Immediate surgery" means that the patient undergoes operation as soon as possible after admission to hospital with massive hæmorrhage, here the amount of bleeding is the decisive factor Surgery after trial is advocated by Avery Jones (1947) and Dunphy and Hoerr (1948), and immediate surgery by Finsterer (1947), Tanner (1949a), and Stewart et al (1948)

TABLE I—PROGNOSTIC SIGNIFICANCE OF VARIOUS SYMPTOMS AND SIGNS

Stenosis and/or cachexia (admitted to hospital because of bleeding no perforation no pain)	15	1	[illegible]
Total	60	16	27

TREATMENT

The treatment was conservative, according to Meulengracht's (1947) principle of early and liberal feeding, administration of ample fluid, and blood transfusion Transfusions were given more often during the latter part of the period than at the outset Only 1 patient was operated on

ANALYSIS

The analysis comprises only 315 hæmorrhages (28 fatal), 2 patients died, from severe meningitis and from severe heart disease, without the hæmorrhage being manifest in life and so are excluded The following factors were studied (1) perforations, (2) hæmorrhage starting in hospital, (3) severe pain in hospital, (4) stenosis and/or cachexia, (5) operation for peptic ulcer, and (6) manifest hæmorrhage in the past (tables I–V)

In table I, if a patient has pyloric stenosis as well as pain he is included in both groups The two perforations listed were chronic, and there was no acute diffuse peritonitis "Bleeding starting in hospital" includes bleeding during ulcer management, "interval bleeding," and bleeding starting in another department (7 patients were transferred from a surgical department, and 1 from a psychiatric department) *Patients who have had* multiple operations are listed only once With *partial gastrectomy taking precedence over gastro enterostomy, the latter over suture, and suture over* other minor interventions, of the 44 patients listed 5 had had partial gastrectomy, 29 gastro enterostomy 7 simple suture, and 3 some other operation coma, or gastro intestinal hæmorrhage, do not show a similar biochemical disturbance.

---

* Supported by a grant from Kong Christian den Tiendes Fond

Many factors complicate head injury, which of themselves may alter the ionic balance of body fluids. Of these only mild water deprivation and chest infection were found with significant frequency among the patients under consideration. However, the chloride ion "retention" of pneumonia (Atchley and Benedict 1930) combines low urinary concentration of the ion with low plasma concentration, and water deprivation has the opposite effect of producing high concentrations in both plasma and urine (McCance and Young 1944). The coexistence of high plasma and low urinary concentrations appears therefore to be the result of neither of these factors acting singly, and in only one patient did they operate simultaneously. Furthermore, other patients in the series suffered mild water deprivation and later developed chest infections following their head injuries without ever displaying such a biochemical disturbance. It is therefore thought unlikely that the disturbance is primarily the result of these complicating factors.

It is unlikely that acid-base balance disturbances have affected our patients, though in one or two instances the plasma bicarbonate ion concentration reached the lower limits of normal. The reaction of all urine specimens was acid, and had there been a tendency to acidosis it might have been expected that the kidney would have excreted chloride ions to compensate, in the usual way. Furthermore, there was no reciprocal correlation between day-to-day variations of plasma chloride and bicarbonate ion concentrations as might have been expected had the increase in the former been compensatory for reduction of the latter.

The hypothesis that the initial fault lies in the inability of the kidney to excrete the chloride ion is supported by Fullerton et al. (1932) who remark:

> "the kidney normally excretes chloride in abundance when the plasma chloride is over 520 mgm.%. The fact that the urine of our patient contained only minimal traces of chloride, while the plasma chlorides were over 600 mgm.%, is ample evidence of the inability of the kidney to excrete this substance."

The detailed data of Luetscher and Blackman (1943) show convincingly that because of the inability of the kidney to excrete the chloride ion, even hypotonic intravenous saline leads to a hyperchloræmia. In only two of their four necropsies were they able to find local renal lesions in the tubules which could in any way account for this lack of chloride ion excretion.

Two isolated observations appear to indicate that the inability to excrete chloride is due to complete tubular reabsorption of the ion. McCance and Widdowson (1939) noted that one of their patients with high plasma chloride and sodium concentrations was excreting inulin freely, so that "it may be assumed that the sodium chloride was passing through the glomerular membranes into the tubules" and then being absorbed again. Luetscher and Blackman (1943) performed a mannitol clearance test in one patient while the electrolyte disturbance was subsiding. This showed a reduction of glomerular filtration to 30% of normal and indicated that 97% of the chloride in this glomerular filtrate was reabsorbed.

Borst has attempted an explanation of these phenomena:

> "but very rarely does one find an increase of sodium and chloride ions in the blood accompanied by an almost complete absence of these minerals in the urine. Those cases in which it did occur had possibly one accompanying condition in common—an insufficient filling of the blood vessels or at least of the arterial system since it appeared in cases of severe hæmorrhage, dehydration, nephrotic œdema, postoperative shock and in some cases of heart failure."

Among our patients, such a hypothesis is difficult to maintain. In cases 2 and 3, early and adequate transfusion was given, and in only one of the remaining four patients was there a severe degree of dehydration.

In view of the diverse diseases in which this metabolic disorder has been found, and the apparent lack of any common primary cause, the question must arise as to whether such changes do not constitute an unusual response by the individual patient. This aspect of disease has recently been discussed fully by Selye (1950). Hyperchloræmia occurs during the counter shock and resistance phases of the General Adaptation Syndrome. The charts of Selye show, however, that the urinary chloride concentration rises simultaneously. Since in our patients the urinary chloride concentration fell, it is difficult to assign them to any phase of the General Adaptation Syndrome; nor would such an assignation yield information about the intimate mechanism involved. It may be noted, however, that the biochemical changes recorded in this paper are similar to those following injections of deoxycortone acetate in man.

In patients with head injury, the further problem arises as to whether intracranial damage specifically initiates this disturbance, or whether the latter is the product of non-specific changes developing during the illness. That kidney mechanisms may be affected by stimulation of the brain has been claimed by Cort (Livingstone et al. 1948) who has reproduced the renal shunt mechanism of Trueta et al. (1947) in cats by stimulating various parts of the brain including the posterior hypothalamus, the sensorimotor cortex, and area 13 on the orbital surface of the frontal lobe. Lewy and Gassman (1935) have produced hyperchloræmia and hypochloruria in cats by unilateral stimulation and subsequent destruction of the paraoptic nucleus of the hypothalamus. Sweet et al. (1948) reported hyperchloræmia in four patients after operation on the frontal lobe, and McLardy (1950) refers to "uræmia" after prefrontal leucotomy. In our patients, the frontal and hypothalamic areas were examined with care. All had contusion of the under surface of the frontal lobes, one had contusions in the hypothalamus, and two had blood clot around the pituitary region. In addition, however, there were often severe contusions elsewhere in the brain, particularly in the temporal lobes. Though at first sight the frontal lobe lesions might seem to support the previous work and suggest a direct relationship with the renal disturbance, their presence should be interpreted with care, for in head injuries the under surface of the frontal lobes is often damaged yet there is no evidence that these metabolic disturbances are common. Nevertheless, the possibility that cerebral damage may lead specifically to metabolic disorders merits further study.

DIAGNOSIS AND TREATMENT

The ward test of Fantus (1936) for urinary chloride concentration is frequently used in clinical practice, and the absence of that ion from the urine is usually taken, following Marriott (1947), to be an indication for treatment with saline fluids. Should this be done in patients with hyperchloræmia and hypochloruria there is a risk of aggravating the condition and producing œdema, particularly of the lung bases. The difficulty may be overcome by estimating both plasma and urinary chlorides. On the present evidence it would seem unwise, if a patient has hyperchloræmia, to give sodium chloride until either the plasma chloride level falls to normal or chloride ion appears in the urine in amounts greater than 1 g. per litre.

Summary

Six cases of severe head injury are described in which there was hyperchloræmia without excretion of the chloride ion in the urine.

It is suggested that the essential mechanism is inability of the kidney to excrete chloride ion. Possible ætiological factors are discussed.

amounted at the most to 3 g per day in the milk feeds Even without urinary, fæcal, or perspiratory excretion, this could not raise the extracellular chloride ion concentration by 50 mg per 100 ml in 24 hours unless dispersed in a volume as little as 6 litres There is no evidence that the extracellular fluid was reduced to anything like this volume The other possibilities are that chloride ions were liberated from the tissues into the extracellular spaces, or that water was absorbed by the tissues from the extracellular spaces This latter hypothesis would, however, involve a concentration of all electrolytes and plasma proteins, of which we have no evidence

Case 2 shows the effect of giving intravenous transfusions of sodium chloride containing fluids to a patient in whom this inability to excrete chloride ion develops Approximately 19 g of sodium chloride were given in this way and the plasma chloride ion concentration rose to very high levels, yet the urinary chloride concentration fell to 0 6 g NaCl per litre

Of the remaining patients, cases 3 and 6 displayed the typical urinary findings with plasma chloride levels exaggerated by transfusions of salt containing fluids Case 4 showed severe water deprivation, and although rehydration restored the plasma protein and sodium ion and chloride ion levels to normal, the urine remained chloride free throughout Case 5 demonstrated the typical urinary findings without the plasma sodium and chloride concentrations being consistently above normal

It will be noted that in three of the five patients in whom the estimation was made, the serum sodium ion concentration was raised in addition to plasma chloride Unfortunately, in none of the patients was the urinary sodium ion concentration estimated

A reasonable hypothesis to account for the facts presented seems to be

1 An unknown mechanism causes reduced excretion of chloride ion by the kidneys
2 In the presence of this, sodium chloride intake by mouth and especially by vein, or mild water deprivation, or both may raise the plasma chloride level above normal without causing the excretion of chloride in the urine

Urea —The urinary urea concentrations in five of the six patients were high, indicating that the raised blood ureas which were present resulted from extrarenal rather than renal causes This conclusion is supported by the absence at necropsy of significant histological damage to the kidneys Such factors as fever, hypotension, chest infection, and inadequate nutrition, which themselves tend to raise the blood urea concentrations, varied with each patient and from day to day, so that it has proved impossible to attribute the high blood urea concentrations to any particular cause

Potassium —In two patients in whom serial determinations were made, the serum potassium ion concentration fell during the course of illness, but in two others the level was normal after the chloride ion disturbance had developed On this evidence, therefore, there would not appear to be a close relation between the serum potassium concentration and the chloride ion changes

POSSIBLE ÆTIOLOGICAL FACTORS

Simultaneous hyperchloræmia and hypochloruria is well established in pædiatric practice and has been previously described in adults in whom it is found in four groups of diseases

1 Disturbances in acid base balance (Fullerton et al 1932, McCance and Lawrence 1935, Allott 1939, McCance and Widdowson 1939)
2 Gastro intestinal hæmorrhage (Allott 1939, Borst 1938)
✓3 Cerebral damage (Allott 1939)
4 Sulphathiazole poisoning (Luetscher and Blackman 1943)

There appears to be no common factor among these groups Analysis of the case histories reveals a marked paucity of renal lesions at necropsy and a very high mortality rate Including our own cases, there are twenty deaths in the twenty nine reported

All authors emphasise the unusualness of the picture they describe, both in disease as a whole, and in the particular disease from which their examples were taken Thus most patients with equally severe degrees of diabetic

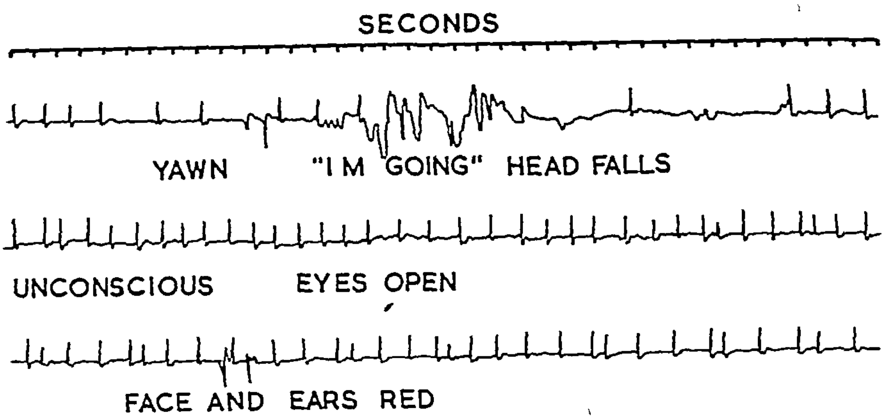

Fig 1—Lead II electrocardiogram at start of faint.

faint and a third at its start The forearm blood flow was measured each minute by the venous-occlusion plethysmographic method, using the principle of Brodie and Russell (1905) The method was similar in detail to that of Barcroft and Edholm (1945), and a pressure of 35 mm Hg was used throughout in the collecting cuff so as to interfere as little as possible with the arterial inflow during the faint

It was impractical to have the subject standing up, so he sat on a high stool with his legs and thighs as nearly vertical as possible He was supported from behind while fainting The room temperature was 19 5°C

RESULTS

The stimulus of seeing venepuncture done on another person was less effective on the second occasion than it had been on the first While preparations were being made, as obviously as possible, the student's forearm blood flow (fig 2) rose from a resting value of about 2 ml. to 7 5 ml. per 100 ml per minute, his arterial pressure rose from 110/78 to 130/88 mm Hg, and his heart rate increased No further increases occurred when the blood was withdrawn. These are normal reponses to an emotional stimulus insufficient to cause fainting

As the subject did not faint, a needle was now inserted into his arm, but no blood was withdrawn There was again an increase in forearm blood flow, but no faint It was therefore decided to increase the stimulus by asking him to drink the few ml of blood he had seen withdrawn from the other person's arm This stimulus was immediately effective, and a negligible amount of blood was swallowed

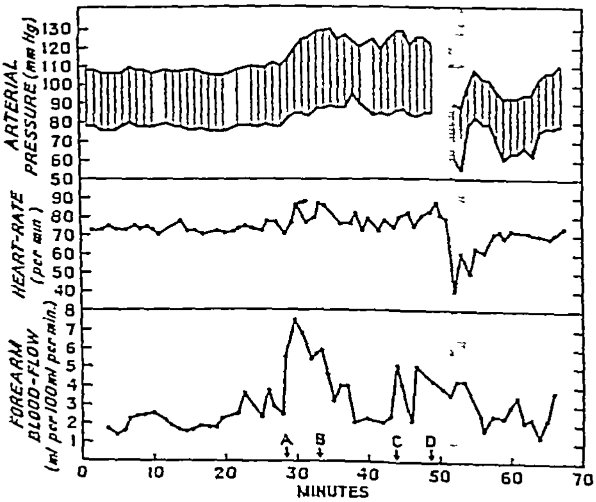

Fig 2—Circulatory changes during emotional faint A watches preparations B watches venepuncture C needle into arm D drinks 5 ml of blood The stippling represents loss of consciousness.

The subject became pale, yawned, and said "I'm going" He lost consciousness, and would have fallen from the stool had he not been supported The heart rate slowed, only 37 beats being recorded in the first minute, and there were consecutive periods of 11 sec and 7 sec during which no QRS complex was detected (fig 1) The electrical record naturally shows a good deal of background swing when the subject slumped forward, but careful inspection shows that it is most unlikely that a QRS complex is lost in this The forearm blood-flow was maintained throughout the period of the faint at 4–5 ml. per 100 ml. per minute, well above the resting level. The first arterial pressure reading during the loss of consciousness was 90/60 mm Hg, but this was about 40 sec after the asystolic periods mentioned above.

As soon as the essential observations had been made, the subject's legs were raised to the horizontal position Consciousness was probably lost for $1^1/_2$–2 minutes During its return one observer noticed some flushing of the ears and face, which is a rather unusual finding The action of the heart was irregular, with coupled beats for several minutes, but this is not unusual (Lewis 1932) During recovery there was an episode of nausea and retching accompanied by renewed slowing and irregularity of the heart beats for about 30 sec This is not shown in fig 1

DISCUSSION

Apart from the insertion of the needle into his arm, the stimuli applied to the subject were all emotional. The needle was sharp and caused little pain If the time relation of the faint to the drinking of blood is taken into account, it seems probable that this faint was mainly of emotional origin

The changes observed in the circulation are similar to those in posthæmorrhagic fainting (Barcroft et al. 1944, Barcroft and Edholm 1945) The combination of increased forearm blood flow and reduced arterial pressure is clear evidence of vasodilatation of the peripheral vessels in the forearm In association with pallor of the skin, this almost certainly means that the vessels to the muscles were dilated Dilatation of the vessels to the muscles in posthæmorrhagic fainting has been shown by Barcroft et al. to depend on sympathetic vasodilator fibres Presumably the same is true of emotional fainting Lewis (1932) has shown by the use of atropine that the slowing of the heart in similar faints is of vagal origin

SUMMARY

Circulatory changes in an emotional faint are described these were similar to those in posthæmorrhagic fainting

My thanks are due to Prof A St G Huggett, in whose department these observations were made, Dr D McK Kerslake and Mr J Hancock, who assisted with the observations, and Mr A. T for fainting

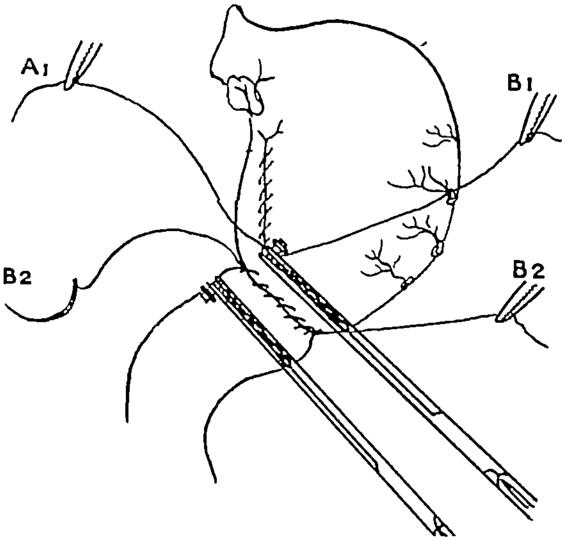

Fig 6—Suture of gastric stump to duodenal stump : A1, B1, and B2 as in fig 5

The gastric stump is now ready for anastomosis, the stoma being held securely in the grip of the small clamp, and the terminal tooth transfixing both walls of the stomach, thus preventing any slipping out at the tips of the clamp The conjoining clamps, and the technique described considerably simplify the preparation of a measured gastric stoma and a new lesser curve, an important step in modern subtotal gastrectomy which both facilitates anastomosis and improves function These light and slender clamps replace the heavier and larger instruments more commonly used in gastrectomy

The clamps also assist in the anastomosis (particularly in the Billroth I operation) by making the gastric and duodenal stumps easily controllable while the posterior seromuscular suture is being placed (fig 6) Similarly, it is an additional advantage (in the Polya operation), although perhaps a small one, to have the selected segment of the jejunum controlled by one of the small clamps (fig 7) The antimesenteric margin of the jejunum can be neatly placed in the grip of one of the clamps by the method described by Pannet (1945) In this way the jejunal opening can be measured to the gastric opening, aligning for the postseromuscular suturing is facilitated, and the clamp tends to seal serosa and mucosa together, thus minimising pouting of the mucosa and oozing By circumcising the seromuscular coats of the gastric stump just below the clamp (Maingot 1941) the vessels in the edge can be identified and ligatured, thus producing a bloodless anastomosis which is completed in the usual way As regards closing the duodenal stump, the rail clamp is useful The same technique is used which has been described for the first row closure of the lesser curve A single seromuscular suture is then placed in the middle of the stump, and the ends of this suture are clipped and held long A three point form of purse-string is placed round each corner The suture in the middle is used as the fourth point of resistance for the burying of each corner Two or three more interrupted sutures complete the closure

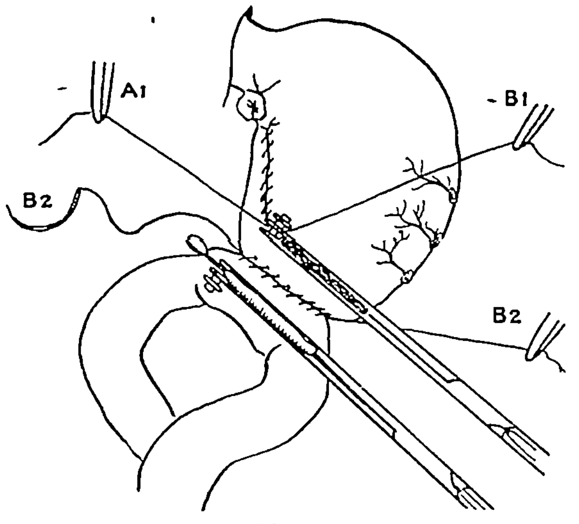

Fig 7—Control of segment of jejunum with special clamp in Polya operation : A1 B1 and B2 as in fig 5 A small needle with margin of redundant jejunum is excised before clamp on jejunum is removed

The conjoining clamps give the same help in resections at the cardia of the stomach The gastric opening is reduced to the size of the œsophageal opening, and the subsequent anastomosis is simplified by having the stomach and the œsophagus in the grip of the two small clamps The conjoining clamps make an end to-end ileotransverse colostomy after a right hemicolectomy a most satisfactory operation The technique used is similar to that described for preparation of the gastric stump, the lumen of the colon being reduced to the size of that of the small bowel

During the past three years I have used these instruments in both the Polya and the Billroth I forms of gastric resection Polya has been used for most of the duodenal ulcers, and Billroth-I for all gastric ulcers The clamps have proved of considerable value in simplifying both forms of gastrectomy, and it is hoped that the instruments may contribute in a small way to the eventual standardisation of technique in partial gastrectomy

I wish to thank Mr H R Thomson for much helpful criticism and advice The clamps are made by T H. Spicer & Son, 45, Marylebone High Street, London, W1

AN EMOTIONAL FAINT

A D M GREENFIELD
M B, M Sc Lond
DUNVILLE PROFESSOR OF PHYSIOLOGY, QUEEN'S UNIVERSITY, BELFAST, FORMERLY SENIOR LECTURER IN EXPERIMENTAL PHYSIOLOGY, ST MARY'S HOSPITAL MEDICAL SCHOOL, LONDON

In 1945 a student, aged 19, fainted and fell while watching blood being withdrawn from another person's arm vein He had previously been healthy and has remained so An attempt was made to cause him to faint again in the same way while under close observation, so that the responses of an emotional faint could be compared with those of posthæmorrhagic fainting described by Barcroft et al (1944) and Barcroft and Edholm (1945) The faint that resulted may *not have* been so purely of emotional origin as the first, but we have very little information about such faints, and there has since been no opportunity of making similar observations on another person So the findings are presented here

METHODS

A lead II electrocardiogram was recorded continuously with an ink writing instrument The Q R S complexes could be identified with certainty, but the record (fig 1) was not good enough for the mechanism of cardiac irregularities to be analysed The arterial pressure was measured at intervals of a minute by auscultation Unfortunately two readings were missed just before the emboli showed it to be of recent but ante mortem origin. The right femoral vein contained a large ante-mortem thrombus which histologically was identical with the embolus

The stomach and intestines were normal, but no appendix was seen, instead there was a small dimple on the cæcum at the point where the appendix usually arises When the cæcum was opened, the appendix was seen to be completely inverted and protruding into the lumen. It measured 5 × 2 cm and was red and inflamed, with gangrene appearing imminent at the tip (fig 1) The remainder of the alimentary tract was completely normal, there being no other lesion from which the hæmorrhage might have arisen Microscopically, the appendix showed considerable disorganisation of the various tissues The epithelial cells were hyperplastic, with papilliferous formations, and there were accumulations of mucin in some areas, surrounded by epithelial formations suggestive of a mucocele (fig 2) The epithelial nuclei were hyperchromatic and showed frequent mitoses There was also subacute inflammation, with much dilatation of the blood vessels

The only other abnormal conditions found were acute passive congestion of the liver, with some fatty change, and mild nephrosclerosis (not excessive for the patient's age)

It was concluded that the cause of this patient's gastro intestinal complaints and of her heavy melæna was complete inversion of the appendix leading to early gangrene of its tip The cause of the inversion was in all probability a mucocele The immediate cause of death was the multiple pulmonary infarctions secondary to thrombosis of the femoral vein

COMMENTS

Neither the clinical picture nor the laboratory and radiological reports suggested the correct diagnosis in this case The profuse bleeding into the bowel in a woman of this age naturally pointed to a carcinoma somewhere along the gastro intestinal tract That an inverted appendix with early gangrene of the tip could cause this hæmorrhage and yet not give rise to some symptoms or signs of trouble implicating the appendix is particularly surprising The complaints had persisted for over three months before death from pulmonary emboli It is impossible to state whether or not the appendix had been completely inverted for the whole of that time, but one might be justified in assuming that at least partial inversion persisted throughout her illness

We are indebted for the early clinical history to Dr H. J Nicholson and Dr W Latimer, who attended the patient before her admission to hospital The photographs of the appendix were taken by Mr George Pendlenton, F I M L T

THE ÆTIOLOGY OF DUPUYTREN'S CONTRACTURE

E G HERZOG
M B Lond
ORTHOPÆDIC REGISTRAR ROTHERHAM HOSPITAL, YORKS

In the two years 1948 and 1949 I saw 20 patients with Dupuytren's contracture at this hospital, 13 attended for the first time, 4 had been on the waiting list from previous years, and in 3 the contracture was an incidental finding For a hospital of 150 beds this seemed a rather large number, and it suggested that Dupuytren's contracture was common in the Rotherham area

Several of the patients raised the question of compensation and would have liked us to say that years of hard work had brought their trouble on It was therefore decided to look into this problem

A review of the literature gives a very confusing picture Astley Cooper (1842) seems to have been first to describe, in 1822, what we today know as Dupuytren's contracture He stated that it was produced by a chronic inflammation of the aponeurosis and thecæ from "excessive action of the hand in the use of hammer, oar, plough, &c" Dupuytren (1832, 1833) established the exact pathology by dissection He, too, thought that trauma was the cause, or, as he put it, it occurred in "people who were obliged to make efforts with the palm of the hand or frequently to handle hard bodies" His first case seems to have been in his own coachman, and the holding of reins for hours on end seemed to him a most reasonable explanation However, already Dupuytren mentions predisposition, and he noticed a similar condition in the foot It is here not quite clear whether he was aware of the thickening of the plantar fascia or whether he was describing what is now known as clawing of the toes

Windsor (1834) stated that his tutor, Henry Cline, jun, had lectured on Nov 8, 1808, on the subject of "permanent contractures of the fingers" and had stated that the "aponeurosis palmaris became contracted and that *cutting of it was efficacious*"

Since then a very large literature on this subject has grown up, and Skoog (1948) lists over 400 references Trauma, single or long continued, has been put forward as a cause time and again by workers in all countries, but as often as this theory has been advanced it has been refuted Among the causes given are gout, rheumatism (Hedges 1896), diabetes, ulnar nerve lesions (Hoffa 1921), tuberculosis, arteriosclerosis, hyperparathyroidism, and neurosis (Reeves 1881) It seems obvious from this list that many earlier writers confused conditions such as hysterical contractures, scarring of skin and tendon, nerve paralyses, and stiff joints with a true contracture of the palmar fascia, but we are here only concerned with the question of the influence of hard work on the development of the contracture

RELATION TO WORK

There are three possible relationships (1) Dupuytren's contracture is always caused by hard work, (2) it is never caused by hard work, or (3) hard work is a contributory cause

There can be no doubt that Dupuytren's contracture sometimes occurs in people who have sustained no injury and have never worked hard in their life Holdsworth (1950) states that he has operated on at least three women in private practice Bunnell (1944) describes a case in a boy of 14 Corlette (1944) says that he himself has Dupuytren's contracture and has not done heavy manual work He emphasises the strong evidence that the condition is hereditary, its occasional occurrence in the plantar as well as in the palmar fascia of affected persons, and its tendency to be bilateral The familial element is brought out well in a family reported by Krogius (1921), in which there were 16 cases in four generations

If Dupuytren's contracture were never caused by excessive strain on the palmar fascia, the incidence in manual and non manual workers should be equal, provided that allowance is made for age and that a sufficiently large number of persons are examined to eliminate the error of chance distribution The same investigator should see both groups and should exclude carefully cases of scarring due to burns or to septic wounds and the stiffness following injury or arthritis I believe that it is of no value to investigate the occupation of patients seen at a hospital Langston and Badre (1948) said that of 88 cases they had collected, 64% were in labourers and 36% in doctors, clerks, and salesmen Kanavel et al. (1929), who found only 30 cases in more than 80 000 admissions, state that there were twice as many non manual as manual workers An objection here is

COMPLETE INVERSION OF THE APPENDIX

T H Boon

ASSISTANT PHYSICIAN, ROYAL VICTORIA INFIRMARY, NEWCASTLE UPON TYNE

J C Sibley
M D Queen's Univ , Ontario
DEMONSTRATOR IN PATHOLOGY IN THE UNIVERSITY OF DURHAM

Complete inversion of the appendix as a result of a previous mucocele seems to be fairly rare The clinical features of the case described here are particularly interesting because during life there were no signs or symptoms indicating that the appendix was at fault The massive melæna which was a prominent early symptom was especially misleading

Fraser (1943) reviewed the published cases of all types of intussusception of the appendix and added 7 of his own, making a total of 82 Of these, only 8 were proven to be complete inversion of the appendix into the cæcum and uncomplicated *by intussusception of* the cæcum or of the ileum Further, in only 6 of the 82 cases was there an intussusception of a mucocele of the appendix It therefore follows that the present case represents a relatively rare condition, for not only had there been a previous mucocele of the appendix but also the appendix had become completely inverted, the ileum and cæcum being normal

In a discussion of the clinical features Fraser emphasised that characteristically there is a very severe colic with periods of complete remission between the colics The interval between the onset of symptoms and the establishment of the diagnosis varied from a few hours to a few months Rigidity and other physical signs pointing to a disorder of the appendix were absent in most cases A barium enema helped in a few cases to establish the diagnosis when a shadow like that of a papilloma could be seen projecting into the lumen of the cæcum Skarby (1941) reported 1 case diagnosed radiologically A second radiological examination after the symptoms had abated showed that the intussusception had undergone spontaneous remission

From his analysis of these cases Fraser concluded that the cause of the intussusception in 6 cases was a mucocele of the appendix, other possible causes being an attempt to extrude a concretion, a papilloma, or a foreign body from the appendix *If the foreign body* or the tumour was in the distal part of the appendix, the intussusception would be of the distal part into the proximal Once developed it may progress to a complete inversion of the appendix or give rise to a compound intussusception, or both

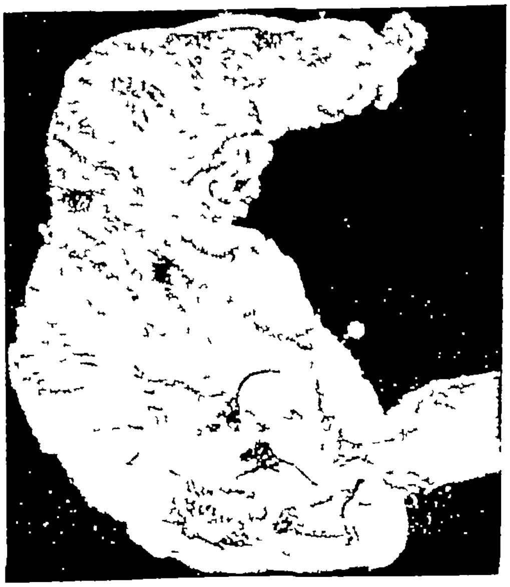

Fig 1—Completely inverted appendix in opened cæcum

CASE RECORD

On the morning of July 24, 1949, a housewife, aged 69, complained of severe diarrhœa, nausea, and passing of blood per rectum Her previous medical history was not relevant Her pulse rate was slightly higher than normal, but there was no evidence of shock There was no abdominal rigidity or localised tenderness, but general moderate tenderness was elicited along the line of the entire colon Gastro-enteritis was diagnosed, sulphaguanidine and kaolin were prescribed, and within a week the patient was well Eight weeks later another attack of diarrhœa came on and two pints of altered blood was passed per rectum After this episode the patient stayed in bed because of weakness, anorexia, and spasmodic abdominal pain, although normal bowel movements were established within a day or two On one occasion her physician felt a doubtful mass just below the hepatic flexure She was seen by one of us (T H. B) three weeks later and, because of persisting symptoms, the anæmia, and loss of weight, carcinoma of the alimentary tract was suspected, and the patient was admitted to hospital

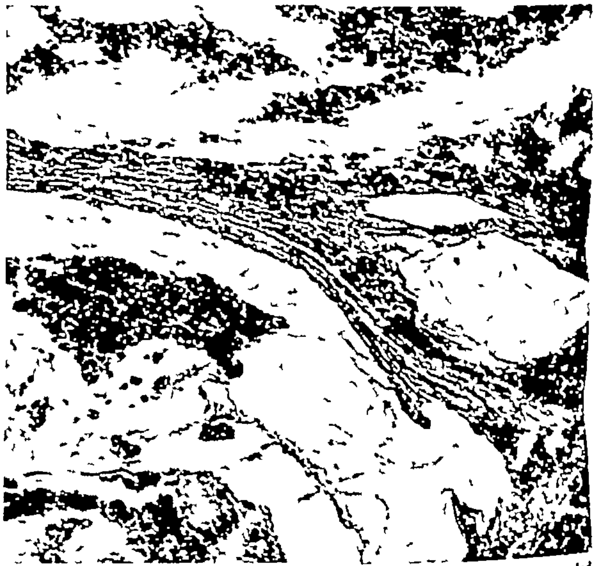

Fig 2—Section of appendix, showing accumulations of mucus surrounded by epithelial formations, suggesting mucocele.

In hospital her general condition remained poor for sixteen days, but she made no specific complaint, and repeated abdominal examinations revealed no mass or tenderness. Her temperature was normal, apart from one rise to 100°F for a few hours Her pulse rate remained at 90–100 Laboratory investigations showed hæmoglobin 58% (8 g), red cells 4,180,000 per c mm , and colour index 0 7 Occult blood was present in three out of four specimens of fæces Gastric analysis revealed free hydrochloric acid No radiological abnormality was detected after a barium meal or a barium enema The diagnosis of carcinoma of the alimentary tract was maintained, and gastroscopy was attempted Difficulty was encountered in passing the instrument, and the examination was discontinued The patient returned to bed in a satisfactory state, but half an hour later she collapsed Her condition steadily deteriorated, and she died fifteen hours later

Necropsy Findings—The body was well nourished, and there were no significant external findings Both lungs were heavy wet, and œdematous, the right weighing 510 g and the left 420 g The lower lobes were atelectatic, and section revealed multiple infarcts Almost all the branches of the pulmonary arteries on both sides contained ante mortem thrombi A little red brown fluid was present in both pleural cavities Microscopy of the lungs confirmed the macroscopical *finding of recent pulmonary infarction and generalised* pulmonary œdema A section through one of the pulmonary emboli showed it to be of recent but ante-mortem origin. The right femoral vein contained a large ante-mortem thrombus which histologically was identical with the embolus

The stomach and intestines were normal, but no appendix was seen, instead there was a small dimple on the cæcum at the point where the appendix usually arises When the cæcum was opened the appendix was seen to be completely inverted and protruding into the lumen. It measured 5 × 2 cm. and was red and inflamed with gangrene appearing imminent at the tip (fig 1) The remainder of the alimentary tract was completely normal, there being no other lesion from which the hæmorrhage might have arisen. Microscopically the appendix showed considerable disorganisation of the various tissues The epithelial cells were hyperplastic with papilliferous formations, and there were accumulations of mucin in some areas, surrounded by epithelial formations suggestive of a mucocele (fig 2) The epithelial nuclei were hyperchromatic and showed frequent mitoses There was also subacute inflammation, with much dilatation of the blood vessels

The only other abnormal conditions found were acute passive congestion of the liver with some fatty change, and mild nephrosclerosis (not excessive for the patient's age)

It was concluded that the cause of this patient's gastro intestinal complaints and of her heavy melæna was complete inversion of the appendix leading to early gangrene of its tip The cause of the inversion was in all probability a mucocele The immediate cause of death was the multiple pulmonary infarctions secondary to thrombosis of the femoral vein

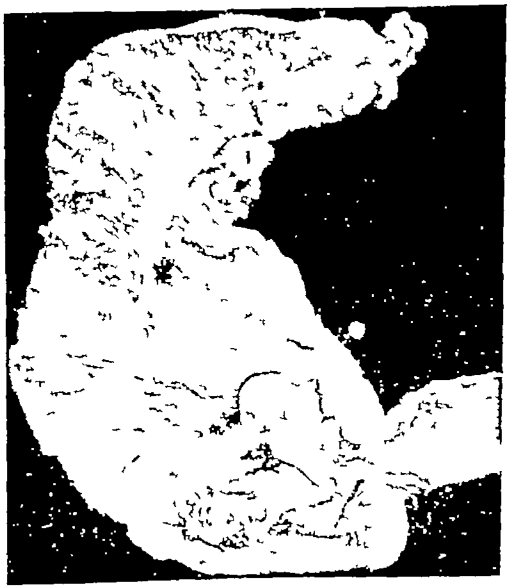

Fig 1—Completely inverted appendix in opened cæcum

CASE RECORD

On the morning of July 24, 1949, a housewife, aged 69, complained of severe diarrhœa, nausea, and passing of blood per rectum Her previous medical history was not relevant Her pulse rate was slightly higher than normal, but there was no evidence of shock There was no abdominal rigidity or localised tenderness, but general moderate tenderness was elicited along the line of the entire colon. Gastroenteritis was diagnosed, sulphaguanidine and kaolin were prescribed, and within a week the patient was well Eight weeks later another attack of diarrhœa came on and two pints of altered blood was passed per rectum. After this episode the patient stayed in bed because of weakness, anorexia, and spasmodic abdominal pain, although normal bowel movements were established within a day or two. On one occasion her physician felt a doubtful mass just below the hepatic flexure She was seen by one of us (T H B.) three weeks later and, because of persisting symptoms, the anæmia, and loss of weight, carcinoma of the alimentary tract was suspected, and the patient was admitted to hospital.

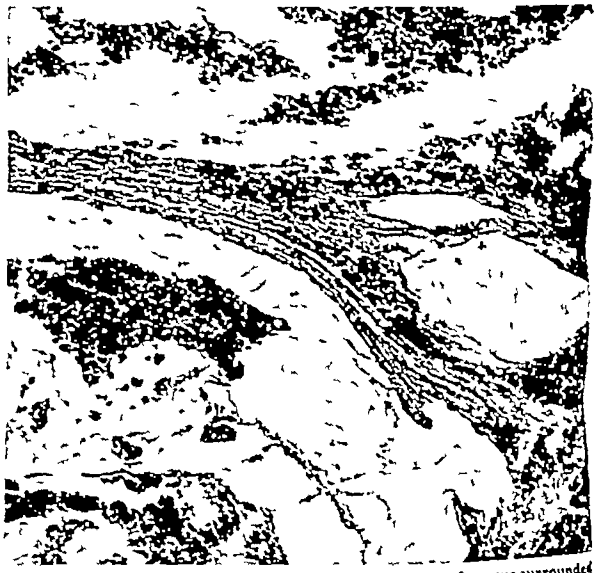

Fig 2—Section of appendix, showing accumulations of mucus surrounded by epithelial formations suggesting mucocele.

In hospital her general condition remained poor for sixteen days, but she made no specific complaint, and repeated abdominal examinations revealed no mass or tenderness Her temperature was normal apart from one rise to 100°F for a few hours Her pulse rate remained at 90–100 Laboratory investigations showed hæmoglobin 58% (8 g), red cells 4,180,000 per c mm , and colour index 0·7 Occult blood was present in three out of four specimens of fæces Gastric analysis revealed free hydrochloric acid No radiological abnormality was detected after a barium meal or a barium enema The diagnosis of carcinoma of the alimentary tract was maintained, and gastroscopy was attempted Difficulty was encountered in passing the instrument, and the examination was discontinued The patient returned to bed in a satisfactory state, but half an hour later she collapsed Her condition steadily deteriorated, and she died fifteen hours later

Necropsy Findings—The body was well nourished, and there were no significant external findings Both lungs were heavy wet, and œdematous the right weighing 510 g and the left 420 g The lower lobes were atelectatic, and section revealed multiple infarcts Almost all the branches of the pulmonary arteries on both sides contained ante mortem thrombi A little red brown fluid was present in both pleural cavities Microscopy of the lungs confirmed the macroscopical finding of recent pulmonary infarction and generalised pulmonary œdema A section through one of the pulmonary

THE LANCET

LONDON SATURDAY, JUNE 16, 1951

“A Very Good Pennyworth”?

“The building of such hospitals, and maintaining f them, will be a great charge to the public especially fter such a War as we are lately got out of” So hey said in 1714 by way of objection to the ambitious cheme of the Quaker John Bellers for hospitals in ondon He was ready for his critics “If medicines an be improved, by which the great miseries, that ttend men by diseases, can be to any degree lessened, he purchase will be a very good pennyworth to the ich, as well as a great charge to the poor” Now, wo and a half centuries later, there has been another var The hospital programme for which Bellers leaded is a fait accompli, but still the question ooms ahead, is it not going to prove too great a harge? Professor Vines, whose letter we print on nother page, comes forward to echo Bellers in the elief that hospitals are “a very good pennyworth,” nd to plead for some attempt to assess the balance n terms of benefit to the community, lest the Chancellor be tempted to stint the pennies Do not our egislators realise, he asks, that the services rendered o some 40,000,000 patients in the year have a nonetary value?

There is much to be said for Professor Vines's oint of view, but if we are going to argue thus we nust do so with our eyes open Bellers apart, it is a new thing to think and speak about hospitals in these terms Public health is one thing, the provision of hospitals something rather different Since the days of Chadwick the pioneers of public health have not hesitated to indicate the economic value of the measures that they have proposed and carried through, but to speak thus of hospital provision is to enter a new and different field Only here and there have hospitals ever been provided with the conscious motive of economic worth to the community Indeed there is danger in thinking at all in such terms The point has been discussed with vigour by Dr Edward Churchill Tracing the history of the non logical (or humanitarian) concept of hospital provision, he writes

> It is of more than passing interest to learn that in England, where the postwar need for industrial production is urgent and skilled labor is in short supply, a logical concept of hospital function in industry has appeared in a few centers such as Birmingham So far neither management nor labor has grasped the utilitarian potential of the hospital”[1]

Dr Churchill, alive to the danger of these trends, adds ‘Developments towards scientific precision in the care of an increasing number of patients offer the temptation to regard the hospital solely as a utility”

Reflection suggests that hospitals have in fact a double function It sould seem that, in approaching the still unsolved problem of the limit to be placed on hospital expenditure in the Welfare State, we must apply two distinct criteria One criterion will be the need of the patient for relief from suffering and pain, and escape from the “spectrum of fear” which Dr Churchill describes as ranging “from the negativism of ignorance to a pressing insistence that things beyond all reason be provided and accomplished” The second criterion will be the need of the community for a wise ordering of its resources so that hospitals shall not be stinted when more spent on them would yield a dividend in terms of national income as measured by the economists and statisticians It is idle to pretend that as a profession or as a country we are ready with the answers All we can hope to do for a while yet is to narrow the issues and try to think more clearly about them We can try to get the history clearer—for the hospital history of this last all important half century has scarcely been recorded, save in the most superficial terms We have heard of new buildings and flag days, of the contributory schemes and white papers, but of the uses to which the hospitals have been put, medically speaking, who can speak with any accuracy at all? We can try, too, to get our statistics into order, so that we can know, not only how many patients have been treated by particular hospitals, but whether they benefited or not, when we can do this it may be possible to make a start on Dr Vines's project for a national balance sheet in terms of man hours lost The new Hospital Administrative Staff College established by King Edward's Hospital Fund (which is mentioned on a later page) intends, it is said, not to limit itself to the training of administrators, but to address itself to the task of creating a milieu in which such matters as these can be discussed and clarified and the inquiry now being undertaken under the auspices of the Nuffield Trust into the function and design of hospitals is also likely to provide valuable data

If these efforts succeed, we may yet see a radical transformation of our whole approach to the problem of hospital costs

Familial Leukæmia

In the transmissible leukæmia of mice at least one of the factors influencing the success or failure of transmission is the animal's genetic constitution Much information has been gathered about the importance of heredity in mouse leukæmia Engelbreth Holm[1] remarked on the lack of firm agreement about the exact mode of inheritance, but observed that inherited susceptibility was a very specific affair, so that one particular strain of leukæmia could be easily transmitted to one family of mice but not to others In order to ensure successful transmission workers use highly inbred, and therefore genetically uniform, susceptible strains, and in addition the animals are previously given a large dose of X rays that temporarily puts out of action their own blood-forming tissues Results obtained with such artificial conditions might be expected to have little relation to human disease, for the genetic uniformity of the susceptible mouse families is never paralleled in man Nevertheless there is some evidence that heredity may influence the incidence of leukæmia in man since it has occurred

Reviews of Books

ndividual Differences in Colour Vision

R W PICKFORD, M A, PH D, D.LITT, *senior lecturer on psychology, Glasgow University* London Routledge & Kegan Paul 1951 *Pp* 386 30*s*

ONCE when a doctor ordered a change of medicine for a hospital patient, a nurse was heard to say indignantly "Purgatives are *our* business " The author of this book s a wise man who realises that sensory neurology belongs neither to psychologists nor to physiologists, but o both Starting as an experimental psychologist who found existing tests for colour-vision *unsatisfactory and* who accepted the Young-Helmholtz theory of colour-vision, Dr Pickford was *driven, as the result of his* findings, to reconsider this theory and the many others put forward

He used chiefly a pair of rotating discs, made up of Hering's *coloured* papers, and a specially designed anomaloscope for coloured filters Other subsidiary methods confirmed his results *He could find no evidence* of the third kind of colour-blindness due to absence or weakness of *the blue* receptors, and *to be* expected on the basis of the Young-Helmholtz theory Moreover, he *found that* yellow vision could vary independently of red, green, and blue sensitivities, and could be normal in *the red-green blind* Further, *brightness-level was* associated in some degree with hue sensitivity, but not always in a *positive* way, and to a large extent it was independent This strongly suggested the hypothesis of a special brightness receptor Dr Pickford tested over 1100 people, and he found neither sensitive normals nor variations nor abnormalities which could not be accounted for by the existence of four primaries, red-green and blue yellow, and a receptor for brightness He therefore believes that all observed *facts of colour-vision are* adequately explained by the theory of Hering with its modification by Houston, *provided white is accounted for,* perhaps as in Granit's theory Other interesting conclusions *relate to the sex-linked red green colour* vision defects, and a number of pedigrees are given Further *points brought out are the absence of sex linkage in the* blue yellow defects, and the relationship of colour defects *to race*

This book is a well arranged and clearly written account of careful work Though definite in his views, Dr Pickford is reasonable about the beliefs of those who think differently , and whether his readers agree with him or not, they cannot fail to be stimulated

Functional Anatomy of the Limbs and Back

W H HOLLINSHEAD, PH D, head of the section on anatomy, Mayo Clinic, Rochester, professor of anatomy, Mayo Foundation, University of Minnesota London *W B Saunders* 1951 *Pp* 341 30*s*

Professor Hollinshead is to be congratulated on his attempt to present a readable *account* of anatomy for "students of physical therapy and others interested in *the locomotor apparatus*" The book has been written primarily for students with only a slight knowledge of biology, and it undoubtedly meets the need of those studying physiotherapy or occupational therapy , for it bridges the gap between the small books and the larger tomes

The book provides a broad outline of the locomotor system and it *has preliminary sections on* histology and the general characteristics of the organs , brief surveys of the head and neck, thorax, and abdomen are included *In the description* of the limbs emphasis is laid on surface anatomy—an aspect especially important *to those who have not the opportunity to* dissect the body The text is supplemented by over a hundred diagrams On the whole *these are simple* and clear and those *of muscles* usually indicate their actions Perhaps, on occasions, the diagrams *are over simplified* for instance, in some of those devised to show muscle actions, reference points such as the general attachments of the muscles are omitted A few diagrams would have been improved by enlargement

Objection might possibly be made to the nomenclature Most commonly the anglicised form of the B N A terminology is used in preference to the Birmingham revision , and this may give rise to confusion in those countries, such as Great *Britain, where the B R is generally accepted* Occasionally, B R words are used in place of those of the B N A This criticism could be *made of other American works, but in these* the alternative nomenclature is usually given in parenthesis Again, *too much space seems to have been devoted* to certain groups of muscles where precise information is relatively *unimportant—for instance,* the deep *muscles of* the back and of the suboccipital triangle, the muscles of facial expression, the small muscles of the foot, and the serratus posterior superior and inferior Space saved by omitting or condensing these descriptions could usefully be employed to amplify the anatomy of the central nervous system, and to include a section on posture and locomotion. Nevertheless this is an excellent book which can safely be recommended to those for whom it is intended

Selected Studies on Arteriosclerosis

R ALTSCHUL, M U DR, professor of histology, University of Saskatchewan Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications 1950 *Pp* 18 40*s*

THOUGH *this work deals almost entirely with the* histology of experimental arteriosclerosis the clear *descriptions and excellent photomicrographs will interest* the clinician as well as the pathologist Professor Altschul's experiments on cholesterol arteriosclerosis were carried out with 14 different techniques, he describes the changes produced in the vessels, and also gives a detailed account of cholesterolosis of organs and tissues He concludes, however, that forty years' work on experimental cholesterol arteriosclerosis has thrown little or no light on the problem of arteriosclerosis in man But Altschul's investigations show that the histological approach is not sterile, though the biochemist may ultimately solve the problem he can do so only in association with the morphologist

Tumors of the Head and Neck

G E WARD, M D, D SO, F A C S, J W HENDRICK M D, M S Baltimore Williams & Wilkins Co *London* Baillière, Tindall, & Cox 1950 Pp 832 114*s*

THIS book places proper emphasis on early diagnosis *and on the value of biopsy The authors* recognise the need for the clinician treating malignant disease to have a sound knowledge *of pathology* , and this aspect is dealt with in each section Throughout this work they compare surgical and radiological treatment, and proclaim their choice as a result of years of experience in each The necessity for adequate follow-up is *not* overlooked but rather than the recommended 5 year *period* some workers would prefer reviews at lengthening intervals for the rest of the patient's life

In the section on cancer of the tongue *and floor* of the mouth, *the work of Butlin is* highly praised , and his advice to remove all small pre *malignant* lesions is quoted *at* length The authors state "if this advice of Butlin had been followed down through the years and all small pre malignant lesions removed, many lives would have been saved the horrible death from *lingual cancer*" For most cases of cancer of the tongue and *floor* of the mouth the authors recommend preoperative *irradiation* followed by hemiglossectomy and block dissection of the neck They suggest *that all* mixed *tumours of the* salivary glands should be completely excised , but they point out *that in some series the* recurrence *rate* has been as high as 40 %, and they attribute this to inadequate removal. There is some force in the argument *that if such* a tumour is small and not increasing in size, it may be *left alone* and the patient kept under *observation* , but since practically all salivary-gland tumours are *radio resistant* treatment is wholly surgical The *authors* are justifiably anxious to extend the surgical treatment of carcinoma of the tonsil They point out that the *outlook* for the patient with *cancer of the* hypopharynx and base of the tongue is not good but there *is cause* for hope that with surgery the *outlook for* these patients will be much brighter Regarding *cancer of the* larynx, they express the opinion that greater standardisation of techniques is necessary *for accurate comparison of the value of* surgical and irradiation therapy, particularly in the early cases

This work is stimulating and useful it contains much valuable information The illustrations are profuse and clear and the whole book is beautifully produced it was held to be "as unscientific as it was unfashionable", but recent advances have changed the picture. Last year, with the Medical Research Council, the foundation received 1 kg. of 'Cortisone' from Merck & Co., of New Jersey, for clinical trial in this country, and the two bodies have set up a joint committee to allocate the drug. In continuation of this side of its work the foundation also made last year a grant to the University of Cambridge to survey the incidence of rheumatism in East Anglia, to the University of Birmingham for research by Prof. M. Stacey, D.SC., F.R.S., on the organic chemistry of tendons, cartilage, and tissues, and to Birkbeck College, where Mr. D. H. R. Barton, D.SC., is attempting to synthesise cortisone from ergosterol. In all, from an income of £550,000 the foundation has distributed over £336,000. It seems to have been money well spent.

SIR WILLIAM GOODENOUGH

Sir William Goodenough, who died on May 23, had many interests in addition to his profession of banking. His activities in medicine grew over a period of many years, starting in Oxford where he was treasurer of the Radcliffe Infirmary. This interest soon spread from the purely financial affairs of hospitals to the whole field of hospital administration. He was quick to see the need for coördinating the service provided by voluntary and local authority hospitals. With the late Alderman William Hyde he was responsible from the beginning for the organisation and administration of virtually all of the Nuffield benefactions. As time passed these benefactions covered a very wide field in medicine. Goodenough was chairman up to the time of his death of the Nuffield Provincial Hospitals Trust, whose basic object is the coördination on a regional basis of the hospital and ancillary services. It is not, perhaps, generally known that the trust's groundwork in the regional field was largely accepted as a basis for the hospital organisation under the National Health Service. Goodenough was governing trustee of the Nuffield Medical Fund for the University of Oxford, which established a series of clinical chairs at the Radcliffe Infirmary in an attempt to raise the status of clinical medicine in Oxford to the very high level attained by the preclinical departments. Many other trusts owed their inception to the inspiration of Lord Nuffield, Will Goodenough, and William Hyde. The last and greatest benefaction was the Nuffield Foundation, which, although not confined to medicine, has already done much to further medical education and research. Goodenough was the original chairman of the foundation, and its work was very near to his heart.

Goodenough's interest in medical education was recognised when he was appointed chairman of the Inter-Departmental Committee on Medical Schools, soon to be known as the Goodenough Committee. The report of this committee was issued in 1944 and has largely been accepted as the official blue print for the development of the medical schools of Great Britain. In two years the committee covered an immense amount of ground, both literal and metaphorical, under difficult war-time conditions.

Will Goodenough's boyish enthusiasm endeared him to all who knew him. It was a great experience to sit on a committee of which he was chairman. He often jokingly pretended that he knew nothing of medical matters, but it was unwise to accept this. He had a wonderful capacity for getting on with the business of a meeting without obvious haste. He would encourage the hesitant, check the garrulous, and destroy the cantankerous with a charm that left no rancour, but only respect and affection. Withal he was often in private diffident and humble to an extent which those who did not know him well found difficult to believe. His services to medicine were very great, and his understanding will be sorely missed.

INTRAVENOUS ADMINISTRATION OF ALCOHOL

Nowadays ethyl alcohol has little place in routine medical treatment, though whisky, brandy, or champagne are still prescribed sometimes as a pleasant adjuvant in threatened circulatory failure. From medieval times alcoholic fumes were used for anæsthesia, and its intravenous administration was described as early as 1668[1], but, because of the complications, this technique did not become popular.

In modern times the complications of intravenous administration have been found to include agglutination or hæmolysis of the erythrocytes, shock, decreased urinary output, and sclerosis of the blood-vessels, but these effects do not appear unless the blood alcohol concentration exceeds 30%, and over 2000 infusions of 5–10% of 95% alcohol in saline or glucose were given without ill effect.[2] The physiological action of alcohol administered parenterally is manifold; it has sedative, hypnotic, analgesic, euphoric, vasodilator, and energy functions. It causes mental sedation with dulling of the memory accompanied by loss of anxiety and a sense of well-being; it also increases the respiration-rate and pulse-rate, and so the body temperature may fall slightly. Thinking remains fairly normal, and the patient does not feel doped. It lessens the sensitivity to pain by affecting first the cerebrum and lastly respiration, in contrast to morphine which depresses the cerebrum and respiratory centres simultaneously. According to Mellanby,[3] a normal person receiving alcohol by mouth can metabolise 10 ml. in an hour. About 98% of the alcohol is completely oxidised as a nutrient for immediate use, and this rate is constant regardless of the concentration in the blood. Thus parenteral administration of a solution of 5% alcohol in 200 ml. glucose within one hour should be safe; and at this rate up to 100–150 g. alcohol can be administered per 24 hours in 2–3 litres of glucose or saline.[2] [4]

Attempts have been made to employ intravenous alcohol during induction of anæsthesia,[5] but it has been used mainly for the postoperative period. Karp and Sokol,[4] who administered it to 2000 surgical patients in a 5–10% solution, found that opiates and other sedatives could be entirely eliminated. They suggested that the first 200 ml. should be infused within 20–30 minutes, and a further 800 ml. within 3–6 hours. In the postoperative period alcohol intravenously may have some value, not only as a sedative and analgesic that does not provoke nausea, but also possibly by preventing pulmonary complications and atelectasis through its influence on the respiratory centres. It seems also to improve the motility of the gastro-intestinal tract and to increase the tone of the bladder. At the same time it improves the immediate postoperative nutritional state by supplying about 550–900 calories in 1 litre of glucose saline. Karp and Sokol,[4] like Mueller,[2] emphasised its merits in undernourished geriatric patients; and Behan has used it as a postoperative sedative since 1925.[6] During the postoperative period some patients, especially the elderly, who have been ill for a long time may become acutely depleted of the B vitamins,[7] which should thus be incorporated in the drip. There is one further possible indication for this therapy. Brown[8] and later Gillespie[9] described its application in status asthmaticus, and both underlined the prompt effect.

of all the available information, including the recommendations of the Spens Report already accepted by both sides In other words, let both sides get together and look at the merits of the case, knowing that there is common desire to apply new monies where the shoe pinches most "

The Ministers' reply did not exclude this wider discussion, but the final paragraph of their letter makes it clear that whatever the findings of any such wider investigation the resultant settlement could be no different

> "The Ministers feel that they ought to make it clear, however, that they could approve proposals which would involve additional Exchequer money only if they covered the points mentioned in the letter of the 23rd May, and that the maximum amount of additional funds which can be made available under present circumstances is £2 million a year "

Faced with this categorical reiteration, the committee felt they had no alternative but to call a special conference of local medical committees, to seek instructions for future action For its part the committee feels that the right course would now be for the Minister of Health "to refer to arbitration the determination of the proper size of the central pool, having regard to the recommendations of the Spens Report and to present day money values " Once the proper size of the central pool had been determined by arbitration the committee would be willing to help "to apply a form of distribution which is in accordance with the recommendations of the Spens Committee and which will enable the best possible medical service to be available to the public "

The gist of this report was made available at the Annual Representative Meeting of the B M A on Thursday

PSEUDOCYESIS—A PSYCHOSOMATIC DISORDER?

THE somewhat cursory account of pseudocyesis that is to be found in most standard textbooks of gynæcology always contains some mention of the patient's mental state, and a report by Fried and his colleagues[1] may throw more light on possible endocrine mechanisms effecting the interaction between psychic and somatic components of the disorder

Bivin and Klinger[2] collected the records of 444 cases in 1937, and apparently only 21 have been reported since then Probably many cases are missed, for in the series now described by Fried et al the case incidence was 1 in 250 of the admissions to a maternity clinic In their series of 27 cases the patients' ages ranged from 18 to 36 All were married, and only 1 had a living child, 11 had never been pregnant The total number of pseudocyesis episodes observed was 36, some patients had had as many as 4 Usually menstrual function was disturbed, 19 patients had hypomenorrhœa, and 7 had amenorrhœa 24 had abdominal swelling Breast changes were common, consisting of enlargement, tenderness, venous engorgement, secretion of cloudy or milky fluid, and darkening of the areola 22 of the women reported fœtal movements In 19 the cervix was found to be softened, of these, 11 had some uterine enlargement but never beyond the size of a six week gestation Increases in weight were usually greater than in normal pregnancy Other symptoms of pregnancy were sometimes present, such as nausea, increased frequency of micturition, and faintness Fried and his associates acknowledge that pseudocyesis may tax the diagnostic acumen of the ablest doctor of their 27 patients 9 had been diagnosed as pregnant by several experienced physicians Wrong diagnosis may give rise to psychological and medicolegal complications In this series the main psychogenic factor was thought to be the intense wish for a child, often motivated by a precarious marital situation, and complicated by superstitions and by early experiences and teaching which had produced fears of pregnancy, but no very convincing evidence for this conclusion is given

By hormonal assays, vaginal smears, and endometrial biopsies it was decided that these women had persistent luteinisation of the ovaries This was believed to be due to ovarian stimulation by the pituitary lactogenic (luteotropic) hormone, and Fried thinks that the psychic factors acted on the endocrine system by pathways from the cortex through the hypothalamus to the anterior pituitary, causing release of the luteotropin and suppression of the follicle stimulating hormone For therapy the patient was first informed of the diagnosis, and this was followed by a psychiatric interview and in some cases psychotherapy, and finally endocrine therapy Curettage was done in some cases Fried argues that just telling the patient the truth is not enough, at best it will only produce a symptomatic cure, with ultimate recurrence, and it may cause suicidal depression The aim of psychotherapy was to get the patient to understand the reasons for her condition Patients who gained only limited insight required adjuvant therapy such as testosterone propionate, to evoke menstrual bleeding, or curettage to demonstrate conclusively that the uterus was empty

THE NUFFIELD FOUNDATION

THE Nuffield Foundation is the responsible and discerning administrator of large funds It has always considered that this trust includes the duty of tendering each year a full account of how it has spent its money and of why it has backed particular ventures, and its sixth report[1] is at once a record of the work of the foundation for 1950–51 and an affirmation of policy

The foundation is now well embarked on its second five year plan It has two avowed aims for this quinquennium The first—to support fundamental biological and social studies—has found ready response. The foundation last year allotted £46,000 to biological projects, including grants to the University of Cambridge for the completion and development, under Prof. F G Young, D SC, F R S, of a mass spectrograph, and for equipment for a team of research workers led by Mr A L Hodgkin, F R S, who are studying the interior of living cells Another grant has been made to University College Hospital Medical School, where Prof C Rimington, PH D, is establishing a unit to investigate the chemistry and biochemistry of blood and the blood pigments in health and disease The grant to the department of Prof J Z Young, F R S, at University College, included provision for bringing electronics to bear on biological problems One result, the flying spot microscope, has already been described in our columns[2] A further £111,000 was allotted to sociological research, and from this sum grants were made for community studies to the University of Birmingham for a midland market town, to the University of Leeds for a local industrial village, and to the University of Liverpool for a dock working community But the foundation's second aim—to encourage specialists to tackle the practical application of abstract knowledge—is apparently proving less attractive An investigation into African education is planned for next year, but it is proving difficult to find contemporary problems on which, without the stimulus of war, scientists are willing to work for the sake of a solution rather than for the sake of new knowledge

The only specific disease with which the foundation is concerned is chronic rheumatism When in 1947 the foundation first began to finance research in this disease,

INTERNATIONAL CONGRESS OF ORTHOPÆDICS

THE Fifth Congress of the International Society of Orthopædic Surgery and Traumatology was opened in Stockholm on May 21 by Prof. Sten Friberg, in the presence of the King of Sweden. The congress was an outstanding social, as well as scientific, success. Hundreds of members from many countries attended with their wives; the exhilarating sunshine of the Swedish spring, the beauty of the city and its waterways, and the lavish entertainments provided by their hosts, culminating with a memorable banquet on the last day of the meeting, left them with the happiest memories of the occasion.

Professor Friberg, reviewing the evolution of orthopædic surgery, suggested that too much emphasis had been laid in the past on purely mechanical aspects; in future it would be necessary to incorporate the great biochemical and biological advances of recent years. This note was struck by many contributors to subsequent discussions.

LOW BACK PAIN AND SCIATICA

Dr. JOSEPH BARR (U.S.A.) reminded his audience that these pains were cerebral and not located, as all patients and too many doctors believed, in the low back and sciatic region themselves. Psychosomatic aspects deserved greater attention, for the unit of treatment was the patient and not his back; it was as important to know what sort of patient had a disease as what sort of disease the patient had. The great technical success of disc surgery (for which, incidentally, Dr. Barr might justifiably have taken most of the credit) must not obscure the fact that at least one third of all patients recovered spontaneously from their first attack, often completely and for ever. And while it was true that 80% of operated cases did well it would be wise to begin to pay some attention to the failures and complications of operation. He still thought myelography advisable, despite the trend away from it, because of the risk of overlooking nerve root tumours or of removing the wrong disc; there was little harm in using a safe water soluble medium which was removed at the same sitting. The surgeon should not delay a necessary operation, for otherwise irreversible root fibrosis and degeneration might develop. He must select cases carefully, always treat the considerable mental component of the disease, and avoid surgery in cases of rapidly progressive degeneration of many discs, which did badly after operation. Operative mortality should be less than 1%, due usually to pulmonary embolism. There was sepsis in some 4% of cases, but superficial sepsis was far less important than the grumbling obscure infection of an intervertebral space which came on with slight symptoms some weeks after operation. Operation inevitably traumatised the elastic spinous ligaments, replacing them with scar, the nerve roots, and sometimes the facets. Structure and function were always somewhat impaired: the dilemma was between minimal exposure and removing enough of the normal architecture to see the lesion properly. Excessive fibrosis, an internal keloid, was particularly likely after facetectomy and might necessitate spinal fusion. Operation could be relied on to relieve sciatica in 9 cases out of 10, but at least every other patient with initial severe low back pain still had trouble with his back after simple laminectomy, and so a combined operation with fusion was preferable. Careful comparison of results showed that the combined procedure offered a moderate but definite advantage over the simpler operation.

Mr. ROBERT YOUNG spoke of the results of operation in nearly 1000 personal cases.[1]

Dr. L. POULANNE (France) reminded the meeting that, because the operation was so recent, the follow up could only be recent; the 20–30 years results were unknown. As the surgeon's experience increased his number of negative explorations decreased, and so did the width of his exposure. It was the 4th lumbar disc that was notorious for recurrences. He fused the vertebræ in only 10–15% of cases and found the indications for fusion still very indefinite; different surgeons often had very different clientèles, and in many cases tables of results could not be meaningfully compared.

Dr. RALPH GHORMLEY (U.S.A.) discussed 2000 cases in which low back pain, with or without sciatica, was a major symptom, which were seen at the Mayo Clinic in a single year. These showed clearly that there were very many causes of such pain other than disc prolapse, even if the number of cases in some of the individual categories might be few. In his series disc lesions accounted for only 22% of cases.

In the discussion the rôle of the intervertebral facets aroused opposing views; some denied altogether that they were ever responsible for symptoms, while others—notably Dr. EDOUARD SAMSON (Canada), M. DELCHEF (Belgium), and M. MARINO ZUCO (Italy)—regarded facet arthritis, often based on anomalies of articular tropism in the lumbar region, as of great intrinsic importance. Swedish workers favoured myelography in diagnosis of disc prolapse. Dr. FOLKE KNUTSSON remarked that a rapidly absorbed water soluble medium, such as 20% 'Abrodil,' need not be removed, though, owing to its irritative properties, preliminary spinal anæsthesia was necessary. Dr. K. LINDBLOM described a striking technical advance which he has introduced—discography, in which the opaque medium is injected directly into the nucleus under radiographic screening, using a transdural approach. The value of this method was confirmed by Dr. P. ERLACHER (Austria). When the offending disc was injected the characteristic pain was evoked; discograms (perhaps we should say nucleograms) were sometimes positive when myelography was negative, and, for those who operated in the lateral position, they indicated the most likely side to approach in cases with bilateral symptoms.

A number of valuable contributions from Swedish investigators dealt with the basic problems of the structure and the normal and pathological physiology of the intervertebral disc. Dr. B. SYLVEN showed some beautiful electron microscope studies demonstrating the three dimensional lattice-gel system of the healthy nucleus pulposus. The fibrils exhibited the typical periodicity of collagen, and were closely bound chemically to the interfibrillar polysaccharide which was responsible for the great water binding power of the nucleus. Disc degeneration with age might consist of a physiological disappearance of this mucoid material, which seemed to be chondroitin rather than hyaluronic acid, with consequent dehydration and fibrillary overgrowth. Dr. PAULSON and Dr. SNELLMAN described physical methods of measuring rates of diffusion within the nuclear mesenchyme.

Mr. JOHN CHARNLEY (Great Britain) described some experiments demonstrating the enormous pressures which could develop within the disc owing to its hydrophylic properties—a hydrophilia of colloid imbibition and not an osmosis—and suggested that acute episodes of turgidity might account for recurrent lumbago or actual herniation. Many other speakers discussed methods and results in lumbosacral fusion, and Dr. L. HULT (Sweden) aroused much interest with his operation of retroperitoneal fenestration of lumbar discs, done as a relatively blind decompression procedure after careful nucleographic study of the last three discs. But it was left to Mr. BRYAN MCFARLAND to voice characteristically, in a delightful

REMUNERATION OF MEDICAL ADMINISTRATORS

ON a later page we print the Industrial Court's award on the claim of administrative medical officers in the hospital service. This award acknowledges the responsibility that these doctors carry, by placing their remuneration more or less on a par with that of consultants. Other medical administrators—and notably full-time public-health workers, who even after the recent increases[1] still count themselves at a financial disadvantage—may be tempted to envy their colleagues in the hospital service; but this latest amendment will provide a strong point in favour of public-health workers when next their remuneration comes under review.

TUBERCULOSIS IN NEIGHBOURING HOUSEHOLDS

SOMETIMES the essential findings of work involving a great amount of detailed study can be stated in one sentence. This is true of an investigation[2] which has shown unequivocally that in the period 1921–48 notifications of tuberculosis from adjacent houses in a typical county borough (Northampton) were more common than would be expected on a random basis; and, further, that these second notifications tended to occur more often within twelve years than would be expected. This result has been obtained only by close study of all notifications in the period and by new statistical techniques. House-to-house infection is the most likely explanation of the result; but it is perhaps unfortunate that Dr Josefine Webb and Dr Alice Stewart, the authors of this study, do not consider other possible causes more fully. True, they exclude the possibility of bias from relations living next door to each other, but there are surely other possibilities. For example, could the result not have been produced by a tendency for neighbours to present themselves for examination when a case of consumption has been found next door? There is a large, though diminishing, pool of undiagnosed cases, and any one group that is examined more often than others may be expected to have a relatively high notification-rate.

It seems, however, that spread of infection accounts for at least some of the excess. The increasing number of workers who attach little importance to superinfection would attribute the preponderance to primary infection of neighbours and their children. There is, indeed, some evidence for this view; for the inclusion of the small number of meningeal and miliary cases with the pulmonary cases increases the percentage excess of notifications in next-door houses from 16 to 20. Since pulmonary notifications are about 15 times as numerous as miliary plus meningeal, it appears that a large part of the excess may be due to the tragic sequelæ of primary infection. Because of this, and the fact that the excess of notifications for other types of tuberculosis was apparently small, it would have been interesting to know something of the state of the milk supply to the town: if for a large part of the time much tuberculous milk was being consumed "other tuberculosis" and, to some extent, meningeal tuberculosis could not be expected to occur especially often as a result of proximity to human sources of infection. Since so much information is given to show that the notifications and deaths for the town follow the usual pattern with regard to housing, economic circumstances, and occupation, this omission is surprising.

This investigation does not seem to indicate a need to alter current practice in the examination of contacts; for, while second notifications from the same house were more than three times as common as would be expected, notifications from adjacent houses were only one-third more common; and thus the number of cases found would scarcely justify the effort. It would seem reasonable, however, to examine neighbours when they have been in close contact, or when the source of a primary lesion in a child cannot be found. Obviously special care is necessary in some of the new housing estates where a high proportion of families have been re-housed because of a case of infectious tuberculosis in the household.

BAGS UNDER THE EYES

"DISCUSS bags under the eyes" would be an interesting, if unpopular, question for the final examination. This common and unsightly condition is often secondary to renal or cardiac disease or hypothyroidism, and treatment of these disorders may cause the bags to diminish or disappear. But there remain the bags which "just growed." What of these? Some light—albeit dim—has been thrown on this question by four anonymous authorities.[1] It seems that various types of food or inhalant allergy are occasionally responsible for bags under the eyes. Drug allergies and allergy to cosmetics may also be involved. Then again, local stasis or œdema in the loose vascular tissue of the lower eyelid may reflect even slight changes in muscle tone, elasticity of the skin, or other factors relating to the patient's general condition. Anæmia, malnutrition, and late pregnancy are other conditions which may give rise to bags under the eyes. It is gratifying to learn that bags are "not necessarily an indication of debauchery and dissipation." The size of the bags may vary at different periods of the year or times of day; relative cardiac insufficiency, not enough to be diagnosed clinically, may produce "evening bags." Bags under the eyes may be familial. One of these American authorities states frankly that "no one knows the exact cause of this condition."

BIRTHDAY HONOURS

THE promotions and appointments to the orders of chivalry announced this year on the King's Birthday include five new medical knights and—a greater rarity—a medical dame. Dr G. S. Todd, who is promoted from C.V.O. to a knighthood in the Royal Victorian Order, has been, since 1934, superintendent of the King Edward VII Sanatorium, at Midhurst, in which the Royal Family have always taken much more than nominal interest. Prof. Hilda Lloyd, F.R.C.O.G., who becomes a dame of the British Empire, is the first woman to have presided over one of the Royal Colleges, and she has created a valuable precedent with dignity and tact.

The new knights bachelor include Mr P. S. Messent, director of surgical studies at the University of Adelaide. The remaining accolades will fall on professorial shoulders nearer home. Prof. C. A. Lovatt Evans, F.R.S., has not only held three chairs of physiology and served University College as an outstanding medical dean, but has presided over Government committees and taken part in the counsels of the Royal Society and of the Medical Research Council. He spent the late war on Salisbury Plain as principal scientific officer at the Experimental Station, Porton. Mr E. F. Finch, a vice-president of the Royal College of Surgeons and lately professor of surgery in the University of Sheffield, has long shown special concern for the organisation of a cancer service to provide timely diagnosis and treatment. Dr J. W. McNee is physician to the King in Scotland and holds the regius chair of medicine in Glasgow; but beyond the borders of Scotland many will remember him as a surgeon rear-admiral in the late war. The profession may be rightly proud of the long list of other medical honours, reproduced on another page, for it testifies to work well done in all parts of the world.

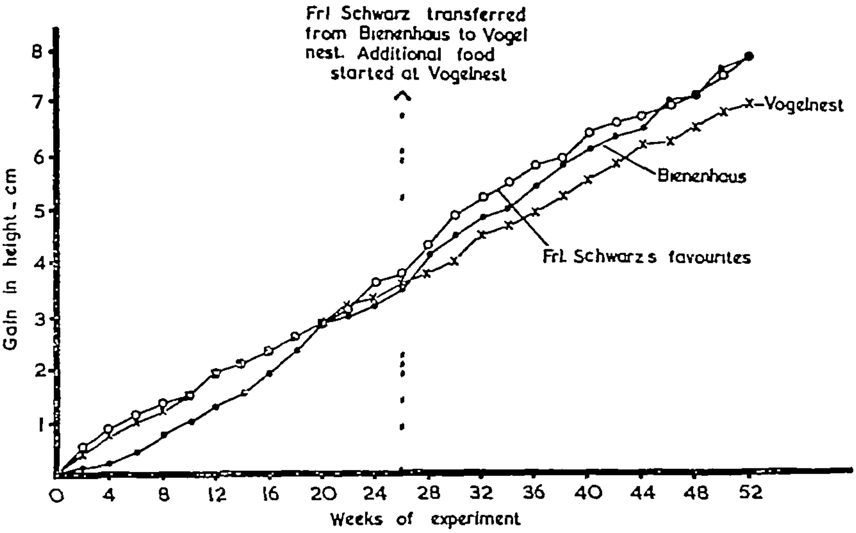

Fig 2—Average growth in height.

d receive any additional food, during the second six months of the homes, Vogelnest, would ipplied with unlimited amounts dditional bread, so that all the dren could satisfy their appetites e full. Extra jam would also rovided to spread on the bread, concentrated orange juice to e as a drink Supplementary d had already been shown to ote excellent growth at another anage (Widdowson 1948) Dur- the second six months the dren at Bienenhaus would con- e to be weighed and measured before but would receive no itional food. In this way it hoped to get a direct com son of the growth rate of dren with and without the itional bread

he children were weighed naked r emptying their bladders, and measurements were always made at the same time lay, at least four hours after the last meal

s the first six months went by it became apparent t the children were gaining weight at very different es at the two homes A group of boys and girls of these s should gain an average of about 1 4 kg in six months Brien et al. 1941) At Vogelnest the average gain was ost exactly 1 4 kg , at Bienenhaus the mean gain was than 0 5 kg

uring the second six months the position was reversed spite of the extra food provided for the children at gelnest, their average growth rate was less than it been during the first six months when no additional d was supplied (fig 1) At Bienenhaus, on the other nd the weight curve immediately began to rise steeply, hough these children were getting only their German ions as before. There was clearly some other factor work which was more than counteracting the beneficial ect of the additional food we supplied

At the beginning of 1948 Bienenhaus was in the arge of Fräulein Schwarz, while Vogelnest was esided over by Fräulein Grün Just at the time when e additional food was first provided at Vogelnest it so ppened that Fräulein Grün left the orphanage to take charge of a children's convalescent home at the seaside Fräulein Schwarz was thereupon transferred from Bienenhaus to Vogelnest, and a third woman, Fräulein Weiss, came to take charge at Bienenhaus Fraulein Grün and Fräulein Weiss were very similar in temperament, bright, happy persons, genuinely fond of the children and the children of them Fräulein Schwarz was quite different She was older, rather stern and forbidding, and she ruled the home with a rod of iron Children and staff lived in constant fear of her reprimands and criticisms, which sometimes seemed quite unreasonable For instance, one day a child was scolded for wearing gloves and getting them wet, the next day the same child was in disgrace for not wearing gloves Fraulein Schwarz often chose the times when the children were at their meals to administer public rebukes and would single out individual children for special ridicule The children had to sit in silence while this was going on, with their bowls of soup in front of them By the time she had finished the soup would be cold, all the children would be in a state of considerable agitation, and several of them might be in tears

Fräulein Schwarz had her favourites, however, and when she was transferred from one home to the other she persuaded the authorities to allow her to take these eight children with her These children could do no wrong and they were always assured of praise rather than blame Their average growth curve has been plotted separately from the others in fig 1 During the first six months, while they were at Bienenhaus, these children gained more weight than the others in the same home, and from the day they went to Vogelnest and got the additional food they started to put on weight very rapidly, so that in the next six months they gained more than twice the standard amount

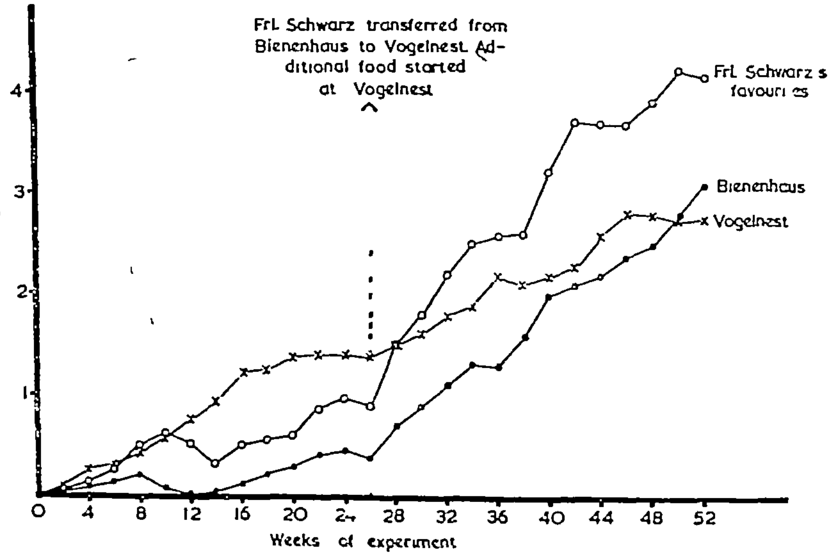

Fig 1—Average growth in weight

Growth in height did not seem to be subject to emotional influences to such an extent as weight (fig 2), but the same trends can be seen

Records were kept of the amounts of food eaten by the children at various stages of the experiment The calories pro mixture of French and English, a general feeling against "trop d'interventions sanglantes" in these cases A disc prolapse was only an acute episode in a chronic spinal disorder, and both conditions could and should be managed conservatively in the great majority of cases

AVITAMINOSIS AND OSTEOPATHY

Dr R ZANOLI (Italy) gave an exhaustive review of the influence of vitamins on the structure and function of bones and joints, and contributions were added by several other Italian workers Dr ANNOVAZZI discussed his experiments in modifying Selye's formalin arthritis in guineapigs by deprivation of ascorbic acid Dr E KODICEK (Great Britain) had also studied the effects of ascorbic acid deficiency on joints and the healing of fractures and soft tissue wounds in the guineapig, chronic deprivation produced a condition in the knees closely resembling rheumatoid arthritis in man

CONGENITAL DISLOCATION OF THE HIP

Here again there was disparity in views on treatment Among the more conservative Dr E SEVERIN (Sweden) maintained with some convincing arthrographic studies that closed reduction should be the standard method of treatment In most cases there was soft tissue interposition between femoral head and acetabulum immediately after reduction, but this interposition usually disappeared spontaneously and did not in itself call for operation Dr A TRÈVES (France) also favoured conservatism, with early functional splintage allowing free movements except adduction, to mould the head and acetabulum and undo any excessive anteversion of the femoral neck Dr E PLATOU (Norway), on the other hand, stated that at least half the cases were left with marked anteversion, and advocated more general performance of rotation osteotomy In this he was supported to some extent by British visitors—Mr J H SEDDON and Mr DAVID TREVOR—who had found a need for rotation osteotomy or acetabuloplasty in selected cases which were not doing well.

SOME OTHER TOPICS

Dr P K DURAISWAMI summarised the experimental work done by him at Liverpool on the causation of skeletal abnormalities by injecting insulin into chick embryos—work which has already been reported,[2] and which may be of the greatest significance for orthopædic surgery in the future Prof J TRUETA, noting that osteomyelitis in which the shaft was primarily involved was often accompanied by overgrowth of long bones, had surmised that this might be due to obstruction of the medullary circulation with a re routing of blood to metaphyseal and epiphyseal vessels, so stimulating epiphyseal growth This was confirmed by experimental ligation of nutrient arteries to the shaft, and the way was now open for the first time to stimulate growth in short limbs by blocking marrow circulation with a bone graft until the inequality in leg length was made up But the results would take much time to assess

Various workers, including Dr SVANTE ORELL (Sweden), discussed the effect of chemotherapy on the management of surgical tuberculosis Earlier and more radical operation was now possible, without the risk of spread of the disease Joint disease might heal without loss of movement in primarily synovial disease treated by total synovectomy, or even when a localised osseous focus had been removed Radical operation on the vertebral focus in Pott's disease was now a practical possibility The great value of streptomycin and *para* aminosalicylic acid was confirmed, more cautiously, by Dr CHAKIR CHAKAR (Turkey) who said that these agents could not be relied on to clear up the disease without orthopædic and operative treatment

Dr JEAN JUDET (France), discussing the treatment of old congenital hip dislocations by a resection reconstruction which replaced the femoral head by the well known acrylic prosthesis invented by himself and Dr R JUDET, gave his audience the opportunity of voicing its appreciation of this new and promising method of hip arthroplasty

The conference is held every three years, and the 1954 meeting will be in Switzerland

MENTAL CONTENTMENT AND PHYSICAL GROWTH

E M WIDDOWSON
D Sc, Ph D Lond

From the Medical Research Council Department of Experimental Medicine, Cambridge

THE observations of Beaumont (1833) on his long suffering subject, Alexis St Martin, a Canadian trapper who had had a gunshot wound which resulted in a gastric fistula, showed for the first time "the effect of violent passion on the digestive apparatus" Later, Pavlov (1910), Alvarez and his associates (see Alvarez 1929), and many others have made notable contributions to our knowledge of the effect of the emotions on the processes of digestion There seems to be no scientific doubt that the secretion of the digestive juices may be induced by pleasurable emotions and inhibited by unpleasant ones It has also been shown that painful emotions will hinder the movements of the digestive tract and that food may remain in the stomach many hours longer than normal if a person becomes frightened or angry after he has eaten a meal

Macy and her co workers (Macy 1942) have made an interesting observation on the same topic, but from another angle They were carrying out long term metabolic studies on women during pregnancy and lactation The mother of one of their subjects died during the investigation, and during the week of emotional disturbance the woman showed a large negative calcium balance in contrast to her positive balance at other times, although she went on eating her usual amount of food Similar observations have also been made on children (Stearns 1951)

Most people would undoubtedly agree in principle with the recommendation of Harington (1608)

> "Use three physicians still, first Doctor Quiet,
> Next Doctor Merryman, and Doctor Dyet"

Nevertheless the importance of getting these three wise men to collaborate in nutritional experiments is often neglected or not appreciated, and the following observations show what may happen when due account is not taken of their advice

Near the industrial town in Germany where our unit had its headquarters in 1948 there were two small municipal orphanages We may call them for the present purpose "Bienenhaus" and "Vogelnest" Each housed about fifty boys and girls between 4 and 14 years of age, the average age was 8 years 8 months in both homes These children had nothing but their official rations to eat, and, although these were considerably better than they had been in 1946 and 1947, they were still barely adequate for the children's requirements The children were below normal as regards height and weight, those at Bienenhaus being a little worse than those at Vogelnest We decided to follow the heights and weights of all these children by weighing and measuring them every fortnight for a year, during the first half of which neither home

[2] Duraiswami P K. *Brit. med J* 1950 ii 381

The prime essential is a continuity of personal supervision for months and years The patients need this, and it pays economically

Already in the South East Metropolitan Region a plan for well placed diabetic clinics has been easily put in action by the cooperation of interested doctors and the keenness of the senior administrative medical officer This Region (see figure) contains many densely populated areas stretching from SE London along the Thames, includes towns and also sparsely populated districts in Kent and Sussex, and sweeps round the coast as far as Brighton It was recognised that the teaching hospitals in this area, Guy's and King's, each needs a diabetic clinic for efficiency and teaching purposes, and these were fortunately already established King's College Hospital has an enormously overweighted department and so has been recognised as the main consultative centre in the region for difficult cases, for training doctors and nurses for diabetic work, and for planned research A few other centres—e g, at Greenwich, Brighton, and Hastings—were already busily established by interested doctors, but many parts of the counties had no centres, so diabetics had to travel 30–50 miles to seek the solution of their problems Practically all these gaps have been filled by the appointment of interested physicians, chosen by the consent of their local colleagues, in various hospital management committee groups

Some of these centres are in their infancy or will never be large But they do provide facilities within reasonable distance for the continuity of inpatient, and (more important) outpatient, guidance by an interested doctor and staff, known and friendly

Two other aspects of treatment are under consideration in regional planning The *tuberculous diabetic* receiving treatment in various sanatoria too often lacks the adequate control of diet and insulin essential for the best results Plans are being made to concentrate such patients in a sanatorium where both aspects of their treatment can be well looked after Secondly, the difficult and not so rare problem of the care of *pregnant diabetics* is felt to merit their concentration in one or two specially experienced centres

It is hoped that, encouraged by the Ministry, all regions will make special arrangements necessary for the best health of diabetics

HOSPITAL ADMINISTRATIVE STAFF COLLEGE

SPEAKING last week at the Hospital Administrative Staff College set up by King Edward's Hospital Fund for London, Mr H A Marquand, Minister of Health, congratulated the Fund on its initiative, and promised the fullest support for its work Hospital management committees, said Mr Marquand, would be encouraged to release administrative officers to attend the college's full course, and arrangements would be made for these officers to remain on full pay He went on to say that in concentrating on short refresher courses for existing administrators, and on long courses for younger students who might be expected to become the administrators of the future, King Edward's Hospital Fund had rightly selected the most important and urgent tasks in this field He understood that there was no lack of applications for the refresher courses, though in this respect London was more backward than the Provinces, and he hoped that boards and management committees in the four Metropolitan regions would take full advantage of the opportunities offered

The college is being operated by the Fund, at a cost of about £20,000 a year, as one of its new functions in connection with the National Health Service The courses—those for younger men will last two years—will be run on the lines of university training, but there will be no examinations or diplomas The college has two houses (at 2 and 14, Palace Court, London, W 8) which contain lecture, administrative, common, and dining rooms, and a library, each house has living accommodation for 12 residents The first course, held in April this year, was attended by 11 senior administrators The second course is now in progress The two-year course will comprise nine months spent in residence at the college, and fifteen months spent on practical work in various hospitals and headquarters of the National Health Service

REGISTRAR ESTABLISHMENTS IN SCOTLAND

THE Department of Health for Scotland has now determined provisionally the establishment of senior registrar and registrar posts within which each regional board may make appointments (R.H B [S][51]7) The Department found that at the beginning of 1950 senior registrars totalled 191 and registrars 269[1] As the following table shows, the total establishment for senior registrars is to be 160 and for registrars 199

Specialty	Region					
	Northern	North eastern	Eastern	South eastern	Western	Total
Senior Registrars						
General medicine Chest medicine	1	4	4	11	19	39
Medical pædiatrics	—	1	1	2	2	6
Dermatology	—	1	1	1	2	5
General surgery	1	4	3	9	13	30
Orthopædics	1	1	1	2	4	9
Otolaryngology	—	1	—	3	4	8
Obstetrics and gynæcology	1	1	1	4	7	14
Psychiatry	1	3	1	3	7	15
Anæsthetics	1	1	1	3	5	11
Radiology and radiotherapy	—	2	2	4	4	12
Ophthalmology	—	1	1	3	6	11
Total	6	20	16	45	73	160
Registrars						
General medicine Chest medicine	2*	5	6	17	23	53
Medical pædiatrics	—	1	1	3	2	7
Dermatology	—	1	1	1	3	6
General surgery	2*	5	5	12	15	39
Orthopædics	—	1	2	3	5	11
Otolaryngology	—	1	1	3	5	10
Obstetrics and gynæcology	—	2	2	5	10	19
Psychiatry	1*	3	2	4	8	18
Anæsthetics	—	2	1	4	7	14
Radiology and radiotherapy	—	2	—	3	5	10
Ophthalmology	—	1	1	4	6	12
Total	5*	24	22	59	89	199

* To be employed in 2nd year only

The establishments, says the circular, are calculated on the following basis

1 The establishments are calculated as training establishments and not by reference to the need to staff hospitals

2 The numbers of those completing training as senior registrars are related as closely as can be estimated to the demand for trained specialists In estimating the demand the Department have taken account of the prospects in the hospital service in Scotland and in the faculties of medicine in the Scottish universities, and also in those fields outside Scotland to which specialists trained in Scotland have customarily proceeded

3 The normal period of training for registrars is assumed to be two years The establishment for senior registrars is calculated on the assumption that the normal training period will be four years instead of three as hitherto assumed The Department intend to discuss with the universities and the profession whether this change should be made, but

---

[1] See *Lancet* 1950 i 1165

vided by the German rations were a little higher at both homes during the second six months than the first, probably as a result of the currency reform, and this no doubt partly explains the increased growth rate at Bienenhaus But during the second six months the children at Vogelnest were undoubtedly eating more than those at Bienenhaus, and nearly 20% more than they themselves had eaten during the first six months, and yet they failed to put on so much weight

This kind of experiment is difficult to "repeat" or "confirm," but there is no doubt that even the most perfectly planned nutritional investigation may be ruined by psychological factors over which the investigator may have no control Those about to embark on feeding experiments would do well to remember "Better is a dinner of herbs where love is than a stalled ox and hatred therewith" (*Proverbs*, xv, 17)

SUMMARY

Work in two orphanages has shown that psychological stresses due to harsh and unsympathetic handling may seriously curtail growth rates

REGIONAL CENTRES FOR TREATMENT OF DIABETES

R D LAWRENCE
M A, M.D Aberd, F R C P
PHYSICIAN IN CHARGE, DIABETIC DEPARTMENT, KING'S COLLEGE HOSPITAL, LONDON

DIABETES is as common a disease as active tuberculosis, but, perhaps because it is not infectious, far less care has been given to its organised treatment At a conservative estimate 3 per 1000 of the population have their health seriously affected by diabetes, and as many more have minor and latent forms It is a disease for which there is no cure at present, and which must be lived with daily and treated largely by the patients themselves As part of their treatment they need *initial training* in the details of their diabetic life, and in diet (with or without insulin), followed by regular supervision, involving special tests and experience Lacking such supervision they will not get the changes of treatment, dosage, and so on, which often make the difference between a healthy working life and semi invalidism These requirements can really only be properly met in special centres created for this purpose

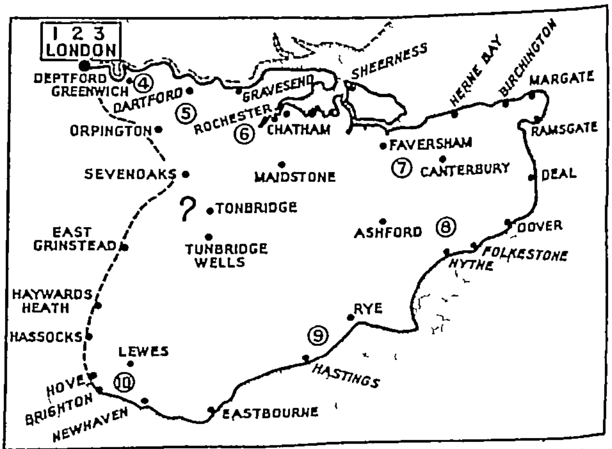
Most busy practitioners, with only about 6–12 diabetics in their care, welcome such centres for most of their patients Most general consultants (and their house physicians[1]) likewise feel that they are ill equipped to deal with diabetics in general wards or afterwards as outpatients Diabetics themselves crowd to any centre where their problems can be helped or solved The Diabetic Association, an organisation of lay diabetics, has been pressing for organised centres for years, and hopes and expects much from the new health service with its possibilities of adequate regional organisation The Ministry recognises the need and is encouraging its planning

To establish centres would be easy and not costly Indeed, it would be economical both in bed requirements and working health For example, all too often the odd diabetic or two in a general hospital is kept for two or three months in an attempt to "stabilise" his condition, and finally referred in despair to a special centre where the "impossible stabilisation" is easily achieved in some ten days Indeed, in one outpatient consultation the life of many "problem" diabetics may be made secure and normal by experienced advice

Numerically the problem is clear At a minimum there are 250 diabetics in 100,000 population, or 1250 in 500,000, which makes a good sized unit for a city And 1 bed is needed for every 50 diabetics (20 beds for a clinic of 1000) to deal with initial treatment and training and for the treatment of relapses and of complications—medical and surgical—which make diabetes at least temporarily more severe and difficult to handle coma and insulin coma, infections, imbalance, gangrene, operations, &c It is obvious that diabetics suffer from all types of added disease, and the doctor in charge must not be a narrow diabetician but a physician widely versed in general medicine

The ideal for adequate treatment of most diabetics is a special centre within reasonable access—preferably not more than 20 miles from the patient's home, though this may be impossible in sparsely inhabited rural areas The same interested doctor should treat them as inpatients and subsequently as outpatients

In a small centre with some 300 diabetics, the doctor needs one sister trained in diets and insulin and able to teach, a nurse to help her, and a cooperative house physician The same team should see the outpatients at their regular visits, at least three or four times a year In outpatient departments ready facilities for testing urine and blood sugar are necessary One experienced doctor with this organised help can deal efficiently with 20–30 patients, the probable number of weekly attendances, in one session, so most of his time will be occupied with other work As the numbers grow (and they grow quickly), more sessions, perhaps another nurse and nurse dietitian, and perhaps a part time registrar, are needed When the clinic grows to 1000 or more, usually necessary for a population of 500,000 and making perhaps the best sized unit, more staff and certain ancillaries are required for full efficiency more medical, nursing, and dietetic help, a part time almoner and a part time chemical technician, and a chiropodist to prevent months of illness from foot sepsis and gangrene The cooperation of the county medical officers and health visitors has been found most useful at several clinics



Regional centres for treatment of diabetes in South-East Metropolitan Region Areas 1 King s College Hospital; 2 Guy s Hospital; 3, Bermondsey and Southwark group; 4 Greenwich and Deptford group; 5 Dartford group 6, St. Bartholomew s Hospital and Medway and Gravesend group; 7 Canterbury group 8 Ashford and Folkestone group; 9 Hastings group; 10 Brighton group ? not yet chosen

BIRTHDAY HONOURS

The list of honours published last week contains the names of the following members of the medical profession

K C V O

Geoffrey Sydney Todd, C.V.O., O.B.E., M.B. Sydney, F.R.C.P.
Superintendent, King Edward VII Sanatorium, Midhurst

D B E.

Prof Hilda Nora Lloyd (Mrs. Rose), M.B. Birm., F.R.C.S.
President, Royal College of Obstetricians and Gynæcologists, professor of obstetrics and gynæcology, University of Birmingham

Knights Bachelor

Charles Arthur Lovatt Evans, D.Sc. Lond., LL.D. Birm., F.R.C.P., F.R.S.
Emeritus professor of physiology, University of London

Ernest Frederick Finch, M.D., M.S. Lond
Formerly professor of surgery, University of Sheffield

John William McNee D.S.O., M.D., D.Sc. Glasg., F.R.C.P.
Regius professor of medicine, University of Glasgow

Philip Santo Messent, M.S. Adelaide F.R.A.C.S.
Director of surgical studies University of Adelaide

C.B (Military)

Major General John Mandeville Macfie, C.B.E., M.C., M.B. Glasg K.H.S., late R.A.M.C.

C.M G

John Merrill Cruickshank, O.B.E., M.D. McGill.
Director of medical services Fiji inspector general, South Pacific Health Service

Herbert John Seddon D.M. Oxfd F.R.C.S.
Member of the Colonial Advisory Medical Committee clinical director Royal National Orthopædic Hospital, London.

John William Field, M.D. Birm.
Director Institute for Medical Research, Federation of Malaya.

C V O

Alexander Greig Anderson, M.D. Aberd F.R.C.P.
Hon. physician His Majesty's Medical Household in Scotland

George Ritchie Mather Cordiner, M.B. St And.
Radiologist, St George's Hospital, London

C B E (Military)

Air Vice Marshal William Edward Barnes, M.R.C.S. R.A.F.

Visiting physician, Tuberculosis Hospital Welisara, and consultant to the Chest Hospital, Ragama, Ceylon.

M B E (Honorary)

Abdul Latif bin Abdul Razak, L.M.S.
Medical officer, Federation of Malaya.

Medicine and the Law

Responsibility in the Operating-theatre

A few weeks ago, in the High Court,[1] a widow with three young children was awarded £2604 compensation for the death of her husband, who died when adrenaline was injected instead of a local anæsthetic for the removal of a cyst

An anæsthetist is personally responsible, not only for doing his work skilfully, but also for seeing that his drugs are correct and that his apparatus is in good working order As his work becomes more complex he must rely on some help from others in the operating-theatre, but whoever has changed the cylinders, got the apparatus ready and prepared drugs for injection the anæsthetist is responsible for ensuring that this work is properly done

Anæsthetists themselves have long been concerned about their responsibilities which have lately been discussed at two important meetings. In Dublin[2] Mr Arthur Cox a lawyer, said

> The anæsthetist is responsible for anything he himself does and anything that falls within the scope of his duty The Court would hold that it is the duty of the anæsthetist to see that the cylinder used is the right cylinder '

[2] *Irish J med Sci.* April 1951 p. 137

even if the final decision is to retain the present three years and the establishment has to be reduced, a temporary addition will have considerable advantages in a period of transition

4 In a few branches of medicine and surgery the normal training period for senior registrars is exceptionally long No special provision for this has been made in the establishment, but it is to be understood that senior registrars in those specialties may remain for an extra year

5 The relative numbers of registrars and senior registrars are calculated so as to permit a progressive selection as training proceeds The extent to which the progress of registrars is reviewed, and the number reduced at the end of the first year, is for each board to determine after consultation with the authorities responsible for medical education The decision on this will determine whether half the registrar posts should normally be first-year and half second year, or whether the fractions should respectively be higher and lower

6 The number of senior registrar posts available to those completing training as registrars will entail fairly severe competition There may be some progressive reduction in the numbers of senior registrars in the course of their training, but, generally, the intention is that once a doctor has obtained a senior registrar post he should be regarded as capable of completing his training and having a reasonable prospect of obtaining a substantive appointment

The circular continues The establishment both at the registrar and senior registrar levels *excludes* the relatively small numbers of university posts in some branches of clinical medicine that are normally held by lecturers of equivalent status in association with clinical duties in a teaching hospital It should be observed, however, that these doctors normally proceed to a senior university post or to the hospital service, and all the higher posts in these fields have been taken into account in assessing the prospects to which the senior registrar establishment has to be related Any material increase in the number of junior university posts would, therefore, in due course increase the number of those competing for the higher posts in the universities or the hospital service, and would, therefore, have to be taken into account in reviewing the size of senior registrar establishments The numbers of those in the senior registrar posts and the junior university posts together must be reasonably related to the prospects, otherwise the future careers of some of the doctors concerned would be seriously prejudiced

In the present circumstances in which a substantial proportion of the posts in laboratory medicine, both senior and junior, are held by members of the university staffs, the Department think it is premature to determine registrar establishments in laboratory medicine The numbers should be adjusted between each regional board and the university concerned, having regard to the general principle on which the other registrar establishments have been calculated, and the agreed numbers notified to the Department

The numbers of senior registrar posts in the several specialties have been adjusted to take account of the needs for specialists in the various fields Provision has been made for sufficient posts at the registrar level in general medicine and surgery to enable those who ultimately elect for a narrower specialty to obtain the necessary fundamental training and experience

In this respect and in others there will have to be a measure of flexibility For example, registrars may elect to spend a period in research work or in hospitals abroad The board will have to decide in each case whether the doctor concerned should be retained in the establishment or treated as supernumerary during this period The essential principle is that in the aggregate the number of those in training should be balanced against the prospects

As the numbers are based on estimates of the need which can only be provisional and will have to be adjusted in the light of experience, the intention is to review the establishments annually each spring in consultation with the regional hospital board so that a beginning can be made with any necessary adjustments in the autumn when it seems likely that most of the new appointments will be made

There is no provision in the establishment for either

1 Registrars whom the board may wish to retain for an extra year primarily for staffing purposes. This is to be regarded as a temporary arrangement to meet staffing difficulties, and such registrars will be treated as supernumerary to the establishment, or

2 Senior registrars who desire to remain for a limited period after the completion of their normal training while they are seeking higher posts The intention is that it should always be open to the senior registrar to take advantage of this, but these appointments also will be supernumerary

Each regional board may now proceed to review the existing appointments and to make new appointments with effect from Oct 1, 1951, within the establishment referred to above Those registrars who do not obtain registrar or senior registrar appointments may be advised, if the board are satisfied that their services are required, that they are likely to be offered supernumerary posts for one year But before any appointments are made to these posts the Department would like to be informed of the number of posts it is proposed to fill

The existing senior registrars, the circular concludes, will fall into one of the following groups

1 Senior registrars in name only, who have in fact completed their training[*] and are employed on essential duties in substantive posts They should be told that until the forthcoming discussions on the present structure of hospital medical staffing are completed the board are unable to reach a final decision as to their future appointment, but that the board are willing to retain them in their present duties until further notice

2 Senior registrars proper, whose training is not yet complete or on the point of completion—i e, in their first, second, or third years Any who cannot find a place within the training establishment as now authorised should have their appointments terminated Any necessary selection should be made on the basis of merit and promise and not merely seniority or stage of training reached

3 Senior registrars who are about to complete their training If they wish, they may remain for a period not exceeding one year on the supernumerary basis mentioned above

R H B HEADQUARTERS STAFF

A DIFFERENCE lately arose between the management and staff sides of committee B of the medical council of the Whitley Councils for the Health Services The staff side's proposals for revised salary scales for the headquarters medical staff of regional hospital boards were not accepted by the management side The matter was referred to the Industrial Court, which has made the following award

Senior Administrative Medical Officers

Regions	*Salary Scales* (£)
Each of the four Metropolitan regions, Birmingham, Liverpool Manchester, and the Western region of Scotland	2500 per annum rising by annual increments of 150 to 3250 per annum
Bristol Leeds Newcastle Sheffield Wales and the South Eastern region of Scotland	2250–150–3000
East Anglia and Oxford	2000–150–2750
Eastern and North Eastern regions of Scotland	1850–125–2475
Northern region of Scotland	1750–100–2250

Deputy Senior Administrative Medical Officers

Each of the four Metropolitan regions Birmingham Liverpool Manchester, and the Western region of Scotland	1650–100–2150
Bristol Leeds Newcastle Sheffield Wales and the South Eastern region of Scotland	1600–100–2100
East Anglia and Oxford	1550–100–2050

These scales will apply to any administrative medical officer fulfilling the functions of a deputy senior administrative medical officer whether or not so designated

Regional Psychiatrists

Each of the four Metropolitan regions Birmingham Liverpool and Manchester	2000–125–2625
Bristol Leeds Newcastle Sheffield and Wales	1900–125–2525
East Anglia and Oxford	1800–125–2425

The new scales of salary set out in the award are to apply from Oct 1, 1950 and a high proportion of dwellings and farms are now connected This policy must have contributed, not only to the advancement of rural amenities and agriculture and the suppression of infectious water borne diseases, but also to the avoidance of cases of cyanosis in infants

---

[*] For the present the normal period should be taken as four years.

Doubtless a similar policy, based partly on chemical analyses including nitrates, has been an important factor in avoiding cases in this country as a whole According to one account,[1] nearly 200 cases of cyanosis in infancy due to well waters have been described , and the country mainly concerned has been the U S.A., with some cases in Belgium and Canada It should be made clear that analyses in the U S.A and in this country are usually expressed in terms of nitrate nitrogen (N) and not as the nitrate radical (NO_3) The suggested provisional limit of 20 p p.m refers to nitrogen However, there must still be numerous dwellings in rural districts using water with over 20 p p m of nitrate nitrogen It would appear that the incidence of cyanosis in infants taking feeds made with water containing this amount of nitrate nitrogen must be very low, and that it may not be high even when the amount approaches 50 p p m

OFFICE MANNERS

SIR,—Prof. Leslie Banks (June 2) appears to have missed the meaning of Brigadier Hardy-Roberts's reference (May 19) to a cup of tea Surely the brigadier was reminding us that the best way to understand fully another man's problem, and possibly to find a mutually agreeable solution, is to talk over the matter in an atmosphere of informality and comradeship This important fact is unfortunately all too often overlooked not only by doctors, but also by those in administrative posts.

London N W 11

BERNARD JOHNSON

PROPHYLAXIS AGAINST TETANUS IN BURNS

SIR —I was interested to read Mr Clarkson's letter (March 24) commenting on the question raised by Dr Colebrook (March 10) of the risk of tetanus in burns Mr Clarkson states that he has seen only 3 cases of tetanus complicating 2000 cases of burns in the course of 10 years

It so happens that I have seen the same number of cases of this 'undoubtedly rare' complication of burns in the past 2 months. I think that those who have had experience amongst primitive communities in the tropics will agree that tetanus is a common complication of all types of injury to the surface of the body As is well known some such cases are due to the ignorant practices which are part of the tradition of the people—for example in some parts of Africa cow dung or mud poultices are applied to the female perineum and infant umbilical cord after delivery Incidentally, the aboriginals in our area, the Konds apply a fresh egg to the umbilical area of their newborn infants which is probably, as it happens the most sterile' thing at their disposal I think that the most important factor making burns complicated by tetanus more common here is the long delay which often separates sustaining of the injury and admission to hospital.

The 1st case seen here on March 30 was of a woman, aged 35 burned 3 weeks previously who had had trismus for 10 days and generalised spasms for 4 days The burns were of 3rd degree over most of both hands and she died several days after being taken home on April 12

The 2nd case was of a boy, aged 20, admitted on May 6, 4 days after sustaining a 3rd-degree burn of the left ankle during an epileptic fit On May 9 he developed generalised spasms with opisthotonos the following day , his condition rapidly deteriorated and he died on the 13th.

The 3rd case is of an epileptic woman admitted on May 17 with a grossly infected 3rd-degree burn of the right foot on the day of admission she had spasms, and the next day opisthotonos

In primitive communities, where difficulties of transport and age old practices delay admission to hospital, routine prophylaxis of all burned patients, whilst indicated for the symptom free, cannot put back the clock for the less fortunate

Udayagiri, Orissa. India.

D STEWART MCLAREN

CORTISONE AND INFECTION

SIR,—I have just read with interest your excellent leading article of April 28, and I am struck with your repeated statement that 'Cortisone' therapy produces hyperadrenalism I presume you are referring to the "Cushingoid" hormonal side effects which are associated with increased glucocorticoid excretion in the urine but I would suggest that the word hyperadrenalism is somewhat misleading in this respect since from an anatomical and physiological standpoint the effect of cortisone upon the adrenal cortex is quite the opposite and in this way fundamentally different from that of A C T H

Just as œstrogen therapy diminishes pituitary follicle-stimulating hormone, so cortisone therapy diminishes pituitary adrenocorticotrophic hormone, and this would seem to explain its beneficial action in those cases of the adrenogenital syndrome which are due to hypercorticism , it also explains the transient hypocorticism which may follow the abrupt termination of a course of cortisone therapy

A leading article is properly concerned only with scientific facts, but in a letter one may perhaps be permitted more latitude There is little at present that can be said *in favour of* combined therapy with cortisone and antibiotics, although some recent reports on its use with chloramphenicol in typhoid fever seem quite *encouraging* , but in this company, which pioneered in the industrial production of the first antibiotic, we remember that penicillin has only been available for ten years and cortisone for less than two Some of us, therefore, look forward, though admittedly through a glass darkly," to a mythical era when cortisone or some suitable substitute, will become the handmaid of improved antibiotics enabling them to penetrate chronic inflammatory tissue and destroy the organisms therein embedded

Medical Director

Merck & Co Ltd Montreal

AMMI VISNAGA

SIR —Those working with the *Ammi visnaga* plant, an active principle of which acts on the coronary vessels, when dealing with the historical aspects cite only the popular herbal tradition in Egypt We believe that the plant s history can be traced still further back.

Maimonides [1] who left us perhaps the oldest pharmacology of the brilliant Hispano-Arabic period, mentions under the name *duqu* (daucus) the Arabic term *al-ahillah* (evidently the same as *khillah*) To contribute to the identification of this plant, he notes that the rays of its umbels were used as tooth picks

Later on the Spaniard Andrés Laguna physician to Charles V and Pope Julius III, in his commentary on the Dioscorides [2] also identifies visnaga with daucus, and gives extensive details about its therapeutic applications at that time—notably, 'to provoke menstruation and urine," uses already described in Dioscorides

Later still, the plant was classified by Lamarck as an ammi (*Ammi visnaga*) This has prompted even some modern botanists to relate visnaga with the ammi of the ancients, erroneously

[1] Glossaire de Matière Medicale Cairo 1940

[2] Pedacio Dioscorides Anazarbeo Acerca de la Materia Medicinal Translated by Andrés de Laguna. Valencia, 1635

with my colleague, Dr R J Reynolds, radiologist to the Kingston group, who, in his department at Charing Cross Hospital, has a 5×4 in apparatus Technically, the requirements of a good chest film are usually obtained on the 5×4 in miniature From the point of view of economy the 5×4 in film, which is single coated, costs 3*d*, whereas the 14×17 in film, normally used now for chests, costs 4*s* 7*d* I came to the conclusion that in a year's work in my own clinic the change over to small film would mean a saving of something like £1000 in film alone The cost of installing apparatus for this work is in the region of £1200, but this cost would be met easily in two years' running Another important point is the greater ease of storage

Comparing the usefulness of the 5×4 in miniature with that of the 35 mm film, I can only agree whole heartedly with Dr Clarke that we will have to readjust our outlook on the roll film The 35 mm film still has great usefulness, I am sure, in the Services for filtering large numbers of personnel, but it is not useful in hospital and clinic services I think we should admit this, and alter our planning accordingly

SINCLAIR R WILSON
Kingston upon Thames Surrey Chest Physician

SIR,—Dr Owen Clarke's proposal deserves every support Fortunately the situation is not as difficult as is suggested by his statement that " equipment for 5 × 4 in radiography is not available in this country "

There are already in existence here some prototypes of a 7 in F/1 5 lens designed to cover a 5 × 5 in plate, these could be modified for mass radiography if required Recently I was permitted to test one of these lenses for this very purpose, and it proved promising The 5 × 5 in aero camera is admirably adaptable to the same needs, and so the complete units could be made in Britain and to British designs as soon as the authorities require them Such a development, I am given to understand, is at present held up by our rearmament programme, but the economics of this decision seem unquestionable

London, W 1 BRIAN STANFORD

CONGENITAL SYPHILIS IN A FIJIAN

SIR,—Your issue of March 17 contained a most interesting letter by Dr Manson Bahr

I spent twelve years in Fiji, and one of the subjects of constant argument was whether a Fijian could contract syphilis Practically all had positive Kahn tests (blood) in those days, and it was not until 1948 that I found two young Fijian males with negative reactions A careful watch was kept for any indications of syphilis in a pure blooded Fijian, and it was in 1948 that I saw, for the first and only time, what appeared to be syphilitic chancres on the genitals of a pure blooded Fijian

The patient was a young soldier who had three sores on the penis (glans and sulcus) all of which on dark field examination showed what the laboratory reported as " spirochætes morphologically resembling *S pallida* or *S pertenue* " The lymphatic glands draining the penile region were enlarged but painless His blood Kahn was ++++ He admitted to contact with pure blooded Fijian girls all of whom had Kahn ++++ Whether he had contact with a non Fijian I cannot say

As treatment was instituted at once no other signs developed, and I could not rightly say that this was definitely syphilis But in twelve years, during which I have seen numerous cases of yaws at all stages, I have never see nor heard of yaws presenting as a penile chancre Has anyone seen such a manifestation ? Like Dr Manson Bahr I wonder if too great zeal in controlling yaws might not open the door to its malignant first cousin—syphilis

METHÆMOGLOBINÆMIA

SIR,—The paper by Dr Ewing and Dr Mayon White in your issue of April 28 is of particular interest because previously no case of cyanosis from nitrates in drinking water had been recorded in the British Isles

Dr Ewing and Dr Mayon White state " theoretically it is possible for coliform organisms to be held back by the soil as water percolates through it, yet for nitrates in solution to pass into a well, in practice this rarely seems to happen, coliform organisms being usually demonstrable in well waters containing nitrates " I suggest that this statement may mislead

Firstly, the great majority of well waters of superlative bacterial quality (many of them used for public supplies) contain small but appreciable amounts of nitrates when the wells are situated in an outcrop formation (e g, 5 p p m of nitrate nitrogen) Under the present climatic conditions there is in some instances a slight increase in nitrate content but without deterioration in bacterial quality On the other hand, examples of well waters free from nitrates are those derived from the chalk under the London tertiary beds, but in such waters reduction has taken place so that a comparable quantity of nitrogen is found in the form of ammonia

Secondly, with regard to the relation between nitrates and coliform organisms in shallow wells at farms and cottages in rural districts, the accompanying table summarises data for 600 such wells, samples from which have been examined in my laboratory Detailed classification of the bacteriological results is omitted for conciseness, but the description of " passable " is based on a low number of coli-aerogenes organisms, with *Bact coli* absent from 100 ml in most instances. It will be seen from these figures that there is only limited correlation between nitrate content and bacteriological pollution, the lowest percentage of satisfactory bacteriological results corresponding to the range of 20–50 p p m of nitrate nitrogen. With regard to variations in an individual well, water from one of appreciable size in a gravel formation has been sampled at monthly intervals for five years, and the content of nitrate nitrogen found to vary between 16 and 32 p p m without serious bacteriological pollution in any sample Out of the total of 600 wells it will be noted that 470 showed a nitrate nitrogen content below 20 p p m, and of these 286 were also of passable bacterial purity, 130 (21 6% of the total) showed a nitrate nitrogen content above 20 p p m, and of these 64 were of passable bacterial purity

Range of nitrate content (p p m nitrogen)	Samples within stated range of nitrate content		Samples of passable bacterial purity within stated range of nitrate content	
	No	%	No	%
<10	357	59 5	216	60
10– 20	113	18 8	70	62
20– 50	103	17 2	47	46
50–100	24	4 0	14	58
> 100	3	0 5	3	—
Total	600	100	350	58

Nitrates represent organic pollution from sources sufficiently distant for oxidation to have taken place through several stages, whereas free ammonia is more commonly an indication of recent pollution However, it has been our practice for very many years to report adversely on the presence of considerable amounts of nitrate nitrogen in terms such as " indicative of derivation from a manurially contaminated soil " About half the samples referred to in the table were from wells at farms in Essex, examined for the public health department, the results tabulated being taken for convenience over the period from 1945 to 1949, although many others were taken in earlier years The percentages are similar if these samples are separated from the other wells at farms and cottages included in the total of 600 The object of the sampling programmes was to obtain improvement in the surroundings of the wells or to replace them by better sources and particularly by a piped supply when necessary Practically the whole of rural Essex is now covered by a network of public water supplies, 0, 1 The jackdaw seemed to remember that it had not taken five baits, it came out again and went along the line of boxes, *bowing its head once before the first box, twice before the second box, and once before the third box* before it opened the fourth and fifth boxes and secured the fifth bait Koehler says that this behaviour "seems to prove that the bird remembered its previous actions" But, if it had done so, surely it would have gone direct to the fourth box Moreover the jackdaw, if it did realise that it had not done its task properly, possibly felt guilty or, at any rate, expected punishment, in which circumstances it is customary for a jackdaw to bow, presenting the nape of its neck to its persecutor or acknowledged superior[3]

MEDICAL ASSOCIATION FOR THE PREVENTION OF WAR

A GENERAL meeting of this association was held at the Royal College of Surgeons on June 8 Dr Duncan Leys was in the chair, and the meeting was attended by 120 doctors In a letter Lord Boyd Orr expressed his support for the association and his willingness to act as one of its sponsors In his opinion war was the worst of the psychological diseases of human society, and its prevention might well be regarded as the most important part of preventive medicine A statement of policy was introduced by Dr Douglas McClean, who pointed out that the extent of the evil resulting from preparation for war was not always realised It hindered social development, produced a shortage of medical supplies, and resulted in widespread development of psychopathological reactions The principal object of the association was to unite doctors in efforts to prevent war, but in working for this object the association would need to undertake diverse activities, including study of the causes of war and of the psychological mechanisms by which people are conditioned to accept war as a necessity It would also be concerned to seek the coöperation of all doctors having the same aims in all countries Dr Martin Pollock reported on a visit he had paid, as a representative of the association to a meeting of French doctors devoted to the same objects he had also been in touch with a doctor who hoped to start a similar movement in Denmark. Dr Alex Comfort read extracts from letters which he had suggested sending to professional representatives in the U S.A and U S S R The bringing together of doctors from such countries to discuss methods for the preservation of peace, on a professional basis, was one of the most valuable contributions which the association could make

Dr Duncan Leys was elected chairman, Dr Douglas McClean vice-chairman, Prof Lionel Penrose secretary, Dr Richard Doll assistant secretary and Dr David Pyke treasurer

---

University of Oxford

On June 2 the following degrees were conferred

D M—E N Allott, J W Gerrard E H Seward J M K Marsh *R H Hardy

B M—J B Dossetor *Tristram Freeman

* In absentia

University of Sheffield

Applications are invited for the J G Graves fellowship for full time medical research The stipend will be £1300 a year Further particulars will be found in our advertisement columns

The following were admitted to the membership

A D H Browne E M. Cheffins A L Jones S G McComb T C Milliken N B O Donohoe D G Simpson H B C Wallace

National Coal Board

Dr S W Fisher has been appointed consultant to the board

Royal Appointment

Surgeon Captain E S McPhail, R.N Z.N, has been appointed an honorary surgeon to the King

Ross Foundation for the Prevention of Blindness

The foundation are inviting applications for part-time research work on any subject related to ophthalmology Further particulars will be found in our advertisement columns

Society of Apothecaries of London

Dr T Jenner Hoskin will deliver the Joseph Strickland Goodall lecture at Apothecaries' Hall, Black Friars Lane, London E C 4, on Tuesday, June 26, at 5 P M He is to speak on Thyroid in Heart disease

Royal Society

On Thursday, June 14, at 4 30 P.M, at Burlington House, Piccadilly, London, W 1, Sir Cyril Hinshelwood, D SC, F.R.S, will describe Some Researches on the Physical Chemistry of Bacterial Cells

Association of Industrial Medical Officers

This association will hold their annual provincial meeting in Sheffield, from July 16 to 20 Further particulars may be had from the hon secretary, Dr J A A Mekelburg, Peek Frean & Co Ltd, Keetons Road, London, S E 16

Addison Lecture

On Thursday, July 5, Prof F G Young D SC, F.R.S, will deliver the fifth Addison lecture at Guy s Hospital Medical School, London, S E 1, at 5 P M He is to speak on Thomas Addison and the Background to 'Cortisone' Further particulars will be found in our advertisement columns

W H O Executive Board

The eighth session of the executive board of W H.O opened in Geneva on June 1 The board has decided to set up a W H O regional office for Africa, and to approve, the nomination of Dr I C Fang as director of the W.H O regional office for the Western Pacific

London Association for Hospital Services

At the annual general meeting on June 6 Dr Russell Brain, P R C.P, was re elected chairman The assets of the association now exceed £65 000, and more than £100,000 has been paid to contributors against the cost of treatment in hospital private wards or nursing homes

A New Guy's

In the next five years about £1 million is to be spent on rebuilding part of Guy s Hospital, London This is the first part of a plan for the complete rebuilding of the hospital during the next fifty years The present plan includes the addition of a new block to house 350 beds, and it is hoped that the hospital will eventually provide 800 beds, compared with the present 575 and 620 before the late war

Royal Society of Tropical Medicine and Hygiene

For the benefit of overseas fellows and other visitors to this country two special meetings of this society are to be held at 26, Portland Place, London, W 1, next month On Wednesday, July 18, Sir *Harold Scott* will speak on British Contributions to Tropical Medicine, and on Thursday, July 19, Prof H E Shortt, F.R S, will give a paper on the Life Cycle of the Malaria Parasite Both meetings will take place at 7 30 P M

Beit Fellowships for Medical Research

The following awards have been made

JUNIOR FELLOWSHIPS

PAMELA M HOLTON M.A Camb, D.PHIL Oxfd To investigate the chemical transmission at nerve-endings at the physiological laboratory University of Cambridge

H F JARVIE B SC M B Glasg To study the psychological manifestations of organic nervous disease at the department of neurology Radcliffe Infirmary Oxford

Obituary

SOPHIA GRAHAM

M B Lond , D P.M

Dr Graham who died on May 8 at the age of 49, was in many ways an exceptional woman. Born Sophia Antonovitch, she was the first Serbian woman to be trained in medicine, for the profession was still closed to women in Yugoslavia when at the age of 19 she was awarded the first scholarship at the Royal Free Hospital by the Women's Medical Mission The intention of the mission was that after qualifying she should return to her country as a pioneer of medical education for women, but after a brilliant career as a student, Toni found herself more attracted to the laboratory than to the clinic or the lecture-room She showed her character by allowing intellect precedence over patriotism Despite the handicaps of language and physical disability, she soon became an important member of the team of workers at the central pathological laboratory of the London County Council's mental hospitals department led by Golla at the Maudsley Hospital

In this group she distinguished herself not only by her quick intelligence but also by the warm personal qualities derived from the South, the Slav, and her sex She was firmly loyal but frankly critical , where she lacked discipline she acquired deftness, where understanding faltered she supplied intuition These gifts were of special value in the studies of the nervous system in which she collaborated with Golla, for their chosen field was in that borderland between physiology and psychiatry where those with more conventional constitutions soon perish from factual starvation In 1932 she took the D P M and shortly afterwards she began the studies of clinical electro-encephalography with which her name will always be linked Her unique value to the laboratory may be measured by the fact that when she married Dr John Graham in 1935, the strict rule requiring women to resign on marriage was waived on her behalf

In 1939 domestic cares began to encroach upon her scientific enthusiasm and she was obliged to retire From that time she helped her husband in his practice, a task which she carried on single-handed during the war For a year before her death she endured with characteristic fortitude the progress of an illness the origin and course of which she was, ironically, well qualified to trace The memory of her fervent spirit will live with her friends and her name will survive with her work

Notes and News

INTERNATIONAL CONGRESS OF CLINICAL PATHOLOGY

THE International Society of Clinical Pathology, which was founded in 1947, is holding its first congress from July 16 to 20 in London The opening ceremony will take place at Friends House, Euston Road, N W 1, at 3 P.M on Monday the 16th, when Sir Lionel Whitby, the president, will give an address on the Science and Art of Medicine The work of the congress has been divided into four sections The section of microbiology will discuss Non bacterial Pneumonias, Bacterial Typing, the Ætiology of Infantile Gastro-enteritis, Systemic Mycoses, Variola vaccinia, and Laboratory Control of Chemotherapy The section of morbid anatomy will hold sessions on the Collagen Diseases, Histological Effects produced in Neoplasms by Irradiation, Physical Methods in Morbid Anatomy, Perinatal Pathology, and Pathology of the Pulmonary Circulation The section of chemical pathology will hear a series of papers on recent advances in biochemistry, including their application to nutritional diseases, disorders of serum proteins, and hormonal assays The section of hæmatology is to discuss Vitamin B_{12} and other Nutritional Factors in the Pathogenesis and Treatment of the Megaloblastic Anæmias, Radioactive Isotopes, Methods of Investigation and Pathogenesis of the Hæmolytic Anæmias, Laboratory Aspects of Transfusion Technique, Effect of Endocrine Organs and Hormones on the Cellular Constituents of the Blood, and Methods of Investigating the Hæmorrhagic Disorders The sections of morbid anatomy and chemical pathology will also hold a joint session on Bone Metabolism, and the sections of chemical pathology and hæmatology a joint session on Pigment Metabolism and Hæmoglobin Members of the congress are to be entertained by the Government, the Royal College of Physicians, the Royal College of Surgeons, the British Medical Association, the Goldsmiths' Company, and the University of London. The congress banquet will take place on July 20 at Grosvenor House Further particulars may be had from the hon secretary, Dr W H McMenemey, Maida Vale Hospital for Nervous Diseases, London, W 9

BIRDS THAT "COUNT"

EVER since the time of Shakespeare's "dancing horse,"[1] Banks's Morocco, which was said to be able to count money, trained performing animals have appeared that seemed able to count There are two ways of counting Obviously an animal can distinguish between one object and two objects of the same kind The animal does not need, even if it could talk, the words "one" and "two," which are merely symbolic of the numbers seen One must keep firmly in mind the fact that a word is merely a symbol of an object The first thing that happens is that one recognises the object , only later does one need a symbol (a noise, a drawing, or a gesture) of that object for the purpose of communication with another person So, in counting, one recognises first the number, and later uses a symbol to express that number Koehler's[2] birds cannot talk , so obviously they cannot count 'one, two, three" either audibly or inaudibly but there is no known reason why they cannot tell the difference between one pea, two peas, and three peas, so long as they can see them practically simultaneously and compare the groups It is no valid objection that a bird watcher entering a hide takes with him a second person, who later leaves the hide, thus deceiving the bird into thinking that the coast is clear, for the bird cannot then compare one person with two and has presumably forgotten how many persons had originally come to the hide Koehler admits this '*Our birds did not count*, for they lack words They could not name the numbers that they are able to perceive and to act upon, but in actual fact they learn to '*think unnamed numbers* ' But by intensive training, with the aid of stereotyped punishment, Koehler taught his birds to distinguish not only between different numerical groups presented simultaneously but also (unlike the bird watching the hide) between different numerical groups presented successively On one occasion an even greater advance was apparently made A jackdaw, trained to open boxes until it had secured five baits, went back to its cage on one occasion after securing only four of the five, which were distributed in the first five boxes in the following order 1 2, 1,

THE TREATMENT OF PSYCHONEUROTICS

SOME PRACTICAL CONSIDERATIONS

W. Lindesay Neustatter
M.D., B.Sc. Lond., M.R.C.P.
PHYSICIAN IN PSYCHIATRY, ROYAL NORTHERN HOSPITAL, LONDON; PHYSICIAN, ST. EBBA'S HOSPITAL, EPSOM

Are psychoneurotics best treated as outpatients or as inpatients? If the latter, in general or special hospitals? How long should they stay? What is the rôle of physical therapy, much in vogue and much quicker than psychotherapy? These are topical questions having regard to problems of medical establishments and the need to make full use of man-power. They are discussed here in the light of experience in general and mental hospitals.

PHYSICAL THERAPY

Opinions about the value of physical treatment in psychiatry vary widely, from Winnicott (1947), who has inveighed fiercely against it—not because it is empirical but because it led away from psycho-analytic explanation of mental disorder—to such enthusiastic exponents as Sargant and Slater (1948), Sands (1946), and Mallinson (1948). But only electroconvulsive therapy (E.C.T.) is relevant to my cases here, and it should be noted that its advocates all emphasise the importance of its judicious use, and the judicious selection of cases. Sands (1946), in particular, has shown that it is essentially the patients with psychotic depression who benefit from it, and warns against its ill effects in hysteria.

All these workers emphasise the need for careful history-taking, and the need to deal with psychological and sociological factors as well. But unfortunately the enthusiasm aroused by finding physical methods of treatment—which, one suspects, in some cases also avoid the necessity of accepting unpalatable psychopathological theory—combined with the ease of administration of E.C.T., is apt to lead to the use of E.C.T. for any patient showing symptoms of depression, without sufficient consideration of whether it is appropriate, or without making allowance for spontaneous improvement.

Preoccupation with physical methods can also induce in trainee psychiatrists a frame of mind which is somewhat disturbing. Thus, one young psychiatrist's *first* idea for the treatment of a moderately severe anxiety state of a year's duration, which was improving, was leucotomy; another wanted an incompletely investigated patient with symptoms of depression to have E.C.T. because "it wouldn't do any harm anyway."

These are two extreme examples, but it is noteworthy how even registrars who go painstakingly into psychogenic factors seem to feel impelled, *immediately* the patient shows any signs of depression, to think in terms of E.C.T., forgetting how commonly it is only a transient mood, which will resolve spontaneously.

This paper is not written in any spirit of hostility to physical treatment as such—I have seen sufficiently good results in appropriate cases—but I feel justified in recording a small series of cases as a reminder that less drastic methods can also be efficacious. These have the advantage of depending on the patients' natural powers of recuperation and thereby enhancing them, and they are free from risk.

For though physical methods are usually safe, nevertheless there is an element of risk, and though this risk may justifiably be taken if the case is severe, the milder the disorder the less warrant is there for taking even a small risk of a serious complication such as the fracture of the neck of a humerus. The physical complications of these treatments are so widely described in psychiatric literature that I do not propose to deal with them here. But I wish to say something about the undesirable psychological sequence.

Treatment being Distasteful to the Patient

That treatment is distasteful is clearly not in itself an absolute contra-indication. But when, as in the case of leptazol, an element little short of terror was introduced, its use was clearly not justified, unless there were very strong grounds for expecting it to succeed where other methods would not.

With E.C.T. this element of suffering is not present. Nevertheless there are patients who fear E.C.T. and refuse to continue with it. Very likely the neurotic element referred to by Sands (1946) is present. Sargant and Slater (1948) emphasise the undesirability of subjecting unwilling patients to this treatment. They emphasise that the response to each shock should be studied, and that there should not be a predetermined number of shocks irrespective of their effects.

A woman, aged 35, came to me after leaving hospital saying she could no longer tolerate another treatment; she was having her nineteenth E.C.T. with no effect. No one seemed to have gone into the history sufficiently to discover that this woman was living alone in a small house with a mother aged 81 and that her life was one of intense boredom. After some talks with me, although her environment could not be changed she improved considerably, but unfortunately she relapsed again in a few weeks' time. My superficial psychotherapy was therefore very little more efficacious than the E.C.T., but, if treatment is to be ineffective it would seem preferable for failure to follow a few talks than to follow nineteen convulsions.

Failure to bring Psychological and Sociological Factors to Light

Sands (1946) refers to the fact that in unsuccessful E.C.T. further probing may reveal psychogenesis, and that the E.C.T. may be diagnostic. I should prefer it the other way round, for there always seems to be a danger that the ease with which E.C.T. can be given may breed a press-button outlook.

Actual Harmful Psychological Sequelæ

Hadfield (1950) has reported a case where the alarm engendered by E.C.T. caused subsequent hysterical symptoms. The following example also shows this, though the "psychic trauma" was of a negative kind, being due to a failure to uncover a source of the anxiety.

A woman, aged 45, developed a pain in the leg. She consulted an orthopædic surgeon, who found nothing wrong and passed her on to a psychiatrist. As she was depressed she was given four electroconvulsive treatments as an outpatient. She was then transferred, as an inpatient with hysterical paralysis of a leg, to another hospital, where I asked her how she had become depressed. Almost immediately she explained that she had been very worried about the pain in her leg, which she thought was due to a growth pressing on a nerve to her leg. Neither the orthopædic surgeon nor the psychiatrist had apparently given her any explanation of the pain. She was vigorously reassured that no organic cause had been found, given a couple of days' rest in hospital, and discharged because the paralysis had disappeared.

CASES TREATED IN A GENERAL HOSPITAL

The series of cases presented here consists of twelve women, aged 21–42, with nothing of note in their family or past history except a tendency to nervousness. One was the hysteric mentioned above; one is described below; and there were ten others admitted to Harold Wood Hospital in the course of a year. They all had diffuse anxiety symptoms of a somatic form, and/or there was undue worrying but no specific phobias. All were depressed, three very much so (two had had suicidal thoughts); two were compensation cases with a hysterical

International Council of Ophthalmology

At a meeting of the council in Paris on May 5, the following appointments were confirmed: president, Sir Stewart Duke-Elder; vice-president, Conrad Berens; secretary, Edward Hartmann (2 Avenue Ingres, Paris, XVIe); treasurer, Marc Amsler. The 17th international congress of ophthalmology is to be held in New York in the autumn of 1954 under the presidency of Bernard Samuels.

Society for Relief of Widows and Orphans of Medical Men

At the annual general meeting of this society on June 6, Sir Ernest Rock Carling, the treasurer, presented the accounts for 1950. At present 39 widows receive grants, and the total amount distributed last year was £5028. The membership of the society is 240. Further particulars may be had from the secretary, 11, Chandos Street, London, W.1.

Conference on School Punishments

Over 200 teachers, doctors, psychologists, and parents met at the House of Commons on June 6 under the chairmanship of Mr Cyril Bibby, M.SC., to discuss Education without Fear. The consensus of opinion at the meeting was that coercion in schools, including specifically the use of corporal punishment, militated against good discipline, which could best be obtained by adult example, a common purpose, and mutual understanding between teacher and taught. A resolution was passed calling upon the Minister of Education to expedite publication of the report on the inquiry into punishment and reward which, in 1947, he asked the Foundation for Educational Research to undertake.

International Research Centre for Chemical Microbiology

The International Research Centre for Chemical Microbiology will be formally opened in Rome on June 25. The centre, directed by Prof. E. B. Chain, F.R.S., is attached to the Istituto Superiore di Sanità, the chief institution for medical research and drug control of the Italian government. The centre, which is recognised by W.H.O., will provide research and training facilities in antibiotics. It is expected to meet the need of countries which lack facilities for basic research on antibiotics, particularly on problems of production. An international symposium will be held on June 25–30 in connection with the inauguration of the centre; speakers from the United Kingdom will include Sir Norman Hinshelwood, F.R.S., Mr D. D. Woods, and Dr A. A. Miles.

Award for Bravery

The King has appointed Dr P. S. London a member of the Order of the British Empire.

In the course of transporting a 35-ton Comet tank through Birmingham it became necessary to unload the tank from the transporter in order that both vehicles could ascend a sharp incline in the centre of the city. When the tank was being remounted on to the trailer it heeled over and fell to the ground, trapping a man between the tank tracks and a parapet wall. Dr London was in charge of the mobile surgical unit which was summoned, and on his arrival he immediately went to the trapped man and commenced anti-shock treatment. In order to release the man hawsers were fixed to the tank which was then slowly raised from the wall on which it was resting. To prevent further injury to the man Dr London jumped into the cavity between the wall and the still moving tank so that he could support him. Dr London was fully aware of the danger that the tank might fall back on him during the lifting operations, but without regard for his own safety he remained with the injured man until the latter had been released and removed to hospital.

Commission on Narcotic Drugs

The United Nations commission on narcotic drugs met in New York from April 10 to May 24. The commission, comprising delegates from Canada, China, Egypt, France, India, Iran, Mexico, Netherlands, Peru, Poland, Turkey, U.S.S.R., United Kingdom, U.S.A., and Yugoslavia, discussed the formation of an International Opium Monopoly, to limit opium production. Unfortunately the delegates were unable to agree on the functions of the proposed monopoly, so it accepted an amended form of a proposal made by France to apply the provisions of the 1931 convention to opium. This proposal provides for: (1) an estimate system, (2) statistical returns, (3) limitation of production and import of opium within the estimates, (4) establishment of national opium monopolies, (5) international control which would permit the imposing of embargoes and local inquiries, and (6) control of the non-medical use of opium.

State University of New York

Dr Perrin H. Long has resigned the chair of preventi medicine at Johns Hopkins University to become executi officer of the department and professor of medicine in th newly created college of medicine at the State University New York. He will take up this post in the autumn.

Petrochemicals Ltd. have now published the second o their technical service leaflets. It is entitled the Handli and Storage of Ethylene Oxide. Copies may be had from the sales department, 170, Piccadilly, London, W.1.

Appointments

BERGIN, J. H. F., M.B. Camb., D.M.R.D.: radiologist, Swindon, Cirencester, and Pewsey area.

CURRAN, A. P., M.B., B.SC. Glasg., D.I.H.: deputy M.O.H. and deputy schools M.O., Luton.

HALLIDAY, H. G., M.B. Glasg.: appointed factory doctor, Oldham west district, Lancs.

JONES, A. G., B.A., M.R.C.O.G.: consultant obstetrician and gynæcologist, Merthyr and Aberdare H.M.C.

LAST, S. L., M.D. Berlin, L.R.C.P.E., D.P.M.: psychiatrist, general and mental hospitals, Aylesbury and district H.M.C.

LEWIS, R. D., B.A., M.B. Dubl., D.A.: consultant anæsthetist, Central Middlesex Hospital, London.

McCLUSKIE, J. A. W., M.B. Glasg., F.R.F.P.S.: consultant physician in charge of wards, Glasgow Western Infirmary.

MELLOR, J. G., M.B. Manc.: chest physician, Plymouth clinical area.

SAMMAN, P. D., M.A., M.D. Camb., M.R.C.P.: consultant dermatologist, Chelsea group of hospitals.

SYRED, D. R., M.R.C.S., D.M.R.D.: radiologist, Northampton and Kettering area.

Diary of the Week

JUNE 17 TO 23

Monday, 18th

UNIVERSITY OF LONDON
5.30 P.M. (Westminster Medical School, Horseferry Road, S.W.1.) Dr Edmond J. Farris (Philadelphia): Male Fertility.

ROYAL SOCIETY OF MEDICINE AND BRITISH MEDICAL ASSOCIATION
10 A.M. (1, Wimpole Street, W.1.) *Festival programme*: Poliomyelitis.
2.15 P.M. Endocrinology.

Tuesday, 19th

ROYAL COLLEGE OF SURGEONS, Lincoln's Inn Fields, W.C.2
3.15 P.M. Dr H. D. Ross: Synovial Reactivities. (Arnott demonstration.)

ROYAL SOCIETY OF MEDICINE AND BRITISH MEDICAL ASSOCIATION
10 A.M. *Festival programme*: Decline of Infant Mortality.
5 P.M. Burns.

WEST END HOSPITAL FOR NERVOUS DISEASES, 40, Marylebone Lane, W.1
2.30 P.M. Mr G. O. Knight: Spinal Compression.

INSTITUTE OF DERMATOLOGY, St. John's Hospital, Lisle Street, W.C.2
5 P.M. Dr L. Forman: Cutaneous Manifestations of Visceral Malignancy.

Wednesday, 20th

ROYAL SOCIETY OF MEDICINE AND BRITISH MEDICAL ASSOCIATION
10 A.M. *Festival programme*: Peptic Ulcer.
2.15 P.M. Experimental Endocrinology.

INSTITUTE OF DERMATOLOGY
5 P.M. Dr R. W. Riddell: Medical Mycology—Systemic Infections.

SOCIETY FOR THE STUDY OF FERTILITY
9.15 A.M. (Girton College, Cambridge.) Opening of two-day conference.

Thursday, 21st

ROYAL SOCIETY OF MEDICINE AND BRITISH MEDICAL ASSOCIATION
10 A.M. *Festival programme*: Nutrition and the B Vitamins.
2 P.M. Neurosurgery.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL, Hyde Park Corner, S.W.1
4.30 P.M. Dr Denis Williams: Neurology lecture demonstration.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 26, Portland Place, W.1
7.30 P.M. Sir Philip Manson-Bahr: *Filariasis in Fiji* (film). Dr H. C. De Souza Araujo: Two New Cultures of *Mycobacterium lepræ hominis* Pathogenic for *Macacus rhesus*.

Friday, 22nd

ROYAL COLLEGE OF SURGEONS
3.45 P.M. Dr Ross: Synovial Reactivities. (Arnott demonstration.)

ROYAL SOCIETY OF MEDICINE AND BRITISH MEDICAL ASSOCIATION
10 A.M. *Festival programme*: Problems of Cardiovascular Disease in an Ageing Population.
2.15 P.M. Orthopædics.

INSTITUTE OF DERMATOLOGY
5.30 P.M. Dr F. R. Bettley: Clinical demonstration.

THE TREATMENT OF PSYCHONEUROTICS
SOME PRACTICAL CONSIDERATIONS

W. LINDESAY NEUSTATTER
M.D., B.Sc. Lond., M.R.C.P.
PHYSICIAN IN PSYCHIATRY, ROYAL NORTHERN HOSPITAL, LONDON; PHYSICIAN, ST. EBBA'S HOSPITAL, EPSOM

ARE psychoneurotics best treated as outpatients or as inpatients? If the latter, in general or special hospitals? How long should they stay? What is the rôle of physical therapy, much in vogue and much quicker than psychotherapy? These are topical questions having regard to problems of medical establishments and the need to make full use of man power. They are discussed here in the light of experience in general and mental hospitals.

PHYSICAL THERAPY

Opinions about the value of physical treatment in psychiatry vary widely, from Winnicott (1947), who has inveighed fiercely against it—not because it is empirical but because it led away from psycho-analytic explanation of mental disorder—to such enthusiastic exponents as Sargant and Slater (1948), Sands (1946), and Mallinson (1948). But only electroconvulsive therapy (E.C.T.) is relevant to my cases here, and it should be noted that its advocates all emphasise the importance of its judicious use, and the judicious selection of cases. Sands (1946), in particular, has shown that it is essentially the patients with psychotic depression who benefit from it, and warns against its ill effects in hysteria.

All these workers emphasise the need for careful history-taking, and the need to deal with psychological and sociological factors as well. But unfortunately the enthusiasm aroused by finding physical methods of treatment—which, one suspects, in some cases also avoid the necessity of accepting unpalatable psychopathological theory—combined with the ease of administration of E.C.T., is apt to lead to the use of E.C.T. for any patient showing symptoms of depression, without sufficient consideration of whether it is appropriate, or without making allowance for spontaneous improvement.

Preoccupation with physical methods can also induce in trainee psychiatrists a frame of mind which is somewhat disturbing. Thus, one young psychiatrist's *first* idea for the treatment of a moderately severe anxiety state of a year's duration, which was improving, was leucotomy; another wanted an incompletely investigated patient with symptoms of depression to have E.C.T. because "it wouldn't do any harm anyway."

These are two extreme examples, but it is noteworthy how even registrars who go painstakingly into psychogenic factors seem to feel impelled, *immediately* the patient shows any signs of depression, to think in terms of E.C.T., forgetting how commonly it is only a transient mood, which will resolve spontaneously.

This paper is not written in any spirit of hostility to physical treatment as such—I have seen sufficiently good results in appropriate cases—but I feel justified in recording a small series of cases as a reminder that less drastic methods can also be efficacious. These have the advantage of depending on the patients' natural powers of recuperation and thereby enhancing them, and they are free from risk.

For though physical methods are usually safe, nevertheless there is an element of risk; and though this risk may justifiably be taken if the case is severe, the milder the disorder the less warrant is there for taking even a small risk of a serious complication such as the fracture of the neck of a humerus. The physical complications of these treatments are so widely described in psychiatric literature that I do not propose to deal with them here. But I wish to say something about the undesirable psychological sequence.

Treatment being Distasteful to the Patient

That treatment is distasteful is clearly not in itself an absolute contra-indication. But when, as in the case of leptazol, an element little short of terror was introduced, its use was clearly not justified, unless there were very strong grounds for expecting it to succeed where other methods would not.

With E.C.T. this element of suffering is not present. Nevertheless there are patients who fear E.C.T. and refuse to continue with it. Very likely the neurotic element referred to by Sands (1946) is present. Sargant and Slater (1948) emphasise the undesirability of subjecting unwilling patients to this treatment. They emphasise that the response to each shock should be studied, and that there should not be a predetermined number of shocks irrespective of their effects.

A woman, aged 35, came to me after leaving hospital saying she could no longer tolerate another treatment; she was having her nineteenth E.C.T. with no effect. No one seemed to have gone into the history sufficiently to discover that this woman was living alone in a small house with a mother aged 81, and that her life was one of intense boredom. After some talks with me, although her environment could not be changed, she improved considerably; but unfortunately she relapsed again in a few weeks' time. My superficial psychotherapy was therefore very little more efficacious than the E.C.T.; but, if treatment is to be ineffective it would seem preferable for failure to follow a few talks than to follow nineteen convulsions.

Failure to bring Psychological and Sociological Factors to Light

Sands (1946) refers to the fact that in unsuccessful E.C.T. further probing may reveal psychogenesis, and that the E.C.T. may be diagnostic. I should prefer it the other way round, for there always seems to be a danger that the ease with which E.C.T. can be given may breed a press-button outlook.

Actual Harmful Psychological Sequelæ

Hadfield (1950) has reported a case where the alarm engendered by E.C.T. caused subsequent hysterical symptoms. The following example also shows this, though the "psychic trauma" was of a negative kind, being due to a failure to uncover a source of the anxiety.

A woman, aged 45, developed a pain in the leg. She consulted an orthopædic surgeon, who found nothing wrong and passed her on to a psychiatrist. As she was depressed she was given four electroconvulsive treatments as an outpatient. She was then transferred, as an inpatient with hysterical paralysis of a leg, to another hospital, where I asked her how she had become depressed. Almost immediately she explained that she had been very worried about the pain in her leg, which she thought was due to a growth pressing on a nerve to her leg. Neither the orthopædic surgeon nor the psychiatrist had apparently given her any explanation of the pain. She was vigorously reassured that no organic cause had been found, given a couple of days' rest in hospital, and discharged because the paralysis had disappeared.

CASES TREATED IN A GENERAL HOSPITAL

The series of cases presented here consists of twelve women, aged 21–42, with nothing of note in their family or past history except a tendency to nervousness. One was the hysteric mentioned above; one is described below; and there were ten others admitted to Harold Wood Hospital in the course of a year. They all had diffuse anxiety symptoms of a somatic form, and/or there was undue worrying but no specific phobias. All were depressed, three very much so (two had had suicidal thoughts); two were compensation cases with a hysterical overlay, none were obsessional, and none psychotic All appeared overwrought and overtired, and were either sleeping badly or insufficiently, and it was because of these last features that I admitted them to hospital

I should add that all the depressions appeared reactive, and, though some constitutional element was probably present as well, none were primarily endogenous in the sense that they were psychotic or appeared to have come on spontaneously The following are two examples

Mrs A, aged 35, had had a bad childhood owing to a broken home While her husband was abroad in the war, she had been greatly troubled by the responsibility of children and financial worries and even now, after the return of her husband, with whom she got on well, she was worried about these things She went to bed at 9 30 P M but was always up between 5 and 6 A M She had had no holiday for years, and was becoming progressively more tired She was lonely in the daytime, had begun to avoid meeting people, had become unsocial and generally nervy, and, when I saw her, was noticeably over tired overwrought, and depressed

Mrs E, aged 40, had no house of her own but was hoping to get one In other ways her domestic life was happy She had to sleep in the same room as her baby, and lacked sleep badly Consequently she had become depressed very easily, tearful, and had thought of committing suicide She also appeared thoroughly overwrought when I examined her

In two other cases the precipitating cause of the depression had been an accident, concerning which litigation was pending These patients had become so anxious and depressed that I thought it necessary to take them into hospital, partly for quietness and sedation, partly to abreact them

TREATMENT

The patients were treated in Harold Wood Hospital, an ex E M S hutted building, light and airy, with pleasant grounds, on the green belt of Essex The usual régime * was to keep the patients in bed for about a week, and then to start getting them up, and to discharge them at the end of two or three weeks A point was made of ensuring sleep during the first week, even if large doses of hypnotics were needed Sometimes the patients were given sedatives in the daytime as well, but nothing approaching "continuous narcosis" was used When they got up they were allowed in the wards, or in the not very extensive grounds, and given occupational therapy, but no other recreation was possible Nor were the patients allowed to leave the hospital premises, as is nowadays generally permitted in mental hospitals Consequently they tended to become somewhat bored and were not averse to going home From the outset it was also made clear that they would not be kept in longer than two or three weeks, and this rule was strictly kept

Psychotherapy was of a simple order I was only visiting once a fortnight at the time, so, except for one or two interviews with me and two abreactions under thiopentone, psychotherapy largely amounted to a sympathetic hearing by a house physician But in view of the importance of the general atmosphere of a ward in producing relaxation, it is relevant that Harold Wood Hospital is a very "happy ship", and that this friendly spirit permeated into the wards, as was shown by the spontaneous testimony of three of the patients, one of whom said she had never known a hospital could be so nice—praise indeed from a neurotic

RESULTS

If the disappearance of all major symptoms is taken as the criterion of recovery, 2 patients recovered (the patient with hysteria referred to above and the one with depression described below) If better sleep, a more rested appearance, and the patients' reports of lessened anxiety and depression are taken as constituting improvement, three improved greatly—two of them in spite of the fact that the external situation remained unaltered, and one clearly owing to learning that at last she had got a better house—six improved moderately, including both the compensation cases, and one who discharged herself, was unchanged

I tried to follow up the cases a year later, but only five patients replied, one of these was the one who had not improved, and the four others had maintained their moderate improvement, including the compensation case

The results are open to the usual criticism of follow ups and criteria of improvement which are largely subjective, but they are probably as accurate as most clinical assessments and numerically the results are significant It can be urged that those patients were clearly a highly selective group and suited to this treatment, but all I am trying to show is that the methods described can be efficacious

My cases were not ones where E C T or leucotomy was indicated, but that they are the type which do get treated by E C T is shown by the fact that one patient had had it, and another had had it prescribed by a colleague of mine who was taken ill and could not give it In my view this second patient primarily needed rest, so I put her to bed for fourteen days, and when my colleague returned he found it unnecessary to give E C T

OPTIMUM STAY IN PSYCHIATRIC HOSPITALS

The length of stay in hospital is an important question both clinically and economically

It will be noted that I discharged my patients within three weeks, as a result of very careful selection The optimum length of stay for psychoneurotics can be a serious problem in psychiatric hospitals, which cannot always select their cases And any shortage of staff may interfere with a rapid discharge rate, and possibly be a factor in the large proportion of patients leaving early against advice, though probably the personality of the patients is the main factor

I analysed a series of cases treated last year at a progressive mental hospital Of 50 men and 50 women selected at random, whose stay averaged nine weeks, 14 recovered and 41 improved On the other hand, 9 men and 10 women (1 obsessional, 2 anxiety states, 8 hysterics, and 8 psychopaths) left within fourteen days, condition unchanged As a lengthy history is taken by the doctor and lengthy inquiries are made by the psychiatric social workers during the first week, this entailed a considerable waste of time in 20% of cases, and is an argument for judicious selection It confirms one aspect of Blacker's (1946) observations on the danger of inpatient facilities being abused "it is an easy way of disposing of awkward cases"

At the other extreme are unduly long stays Of the same 100 patients 7 were in hospital longer than six months, including 2 psychopaths who stayed for fifty two weeks and forty four weeks

The following figures of cases diagnostically comparable to mine, kindly furnished by a neurosis hospital, show that of 58 women with anxiety states or reactive depressions 22 stayed less than a month (16 improved), 20 stayed three months (18 improved), 14 stayed six months (12 improved), and 2 stayed longer than six months (both improved) In spite of the good results, these are long periods off work, and one wonders how far they could be reduced This is a thorny point, which troubled the military authorities during the late war

---

* A thoroughly old fashioned one which I had found useful in Army hospitals I am referring to base hospital treatment not battle casualties

TREATMENT OF PSYCHONEUROTICS IN MENTAL HOSPITALS

In a mental hospital a valuable part of the rehabilitation of recovering psychotics is to get them to mix, to encourage normal interests, and to get them back to work. To facilitate these laudable aims, many and varied recreations and interesting occupational therapy are arranged. The patients are given weekend leave; efforts are made to find them work outside the hospital, even while still resident there; and everything is done to make their surroundings as pleasant and “uninstitutional” as possible. With psychotics these provisions are beneficial, for they are anxious to get out and reassert themselves as normal. With psychoneurotics, unfortunately, they often tend to act as a counter-incentive to recovery, for the neurotic has not got to prove himself anew, and admission to hospital is an excellent escape from the difficulties of life outside. Consequently such patients may develop secondary hysterical reactions with an outcrop of symptoms, and even suicidal threats, at the suggestion of discharge.

Some patients undoubtedly have very real difficulties, and very unpleasant situations to face at home; but, just as it is harder to settle down to work after a month on the Riviera than after a wet fortnight observing the houses facing “Sea View,” so the easier life is in hospital the harder is the return to the outside world. It is of course, in hysterics and psychopaths especially that the distaste for relinquishing a congenial life of arts and crafts for the hard world outside is most noticeable, as exemplified by a chronic psychopathic patient of mine whom I urged to start picking up the threads of his old work. “I get you, Doc,” he said, “You mean I'm to get fit by work,” He paused, and added: “Or, of course, I might do it through playing tennis”—a prescription that he industriously carried out by regularly playing execrable tennis, but with no therapeutic result.

What is the solution? Clearly no one is deliberately going to make hospitals uncongenial and unattractive. Nor is it desirable to reverse the present tendency of treating psychotics and psychoneurotics in one hospital, for this helps to break down the artificial distinction leading to the belief that there is something shameful about mental illness.

INDICATIONS FOR OUTPATIENT AND INPATIENT TREATMENT

The best solution where possible is not to admit psychoneurotics to hospital at all, a view in keeping with Blacker's (1946).

For therapeutic purposes psychoneurotics can be considered under three heads:

1. Those with severe intractable but specific symptoms, such as phobias and obsessions, who, though of generally good personality, are unlikely to benefit much from psychotherapy.
2. Those who have developed either anxiety or depression in association with feelings of inferiority, shyness, difficulty in mixing, &c. as a result of emotional difficulties brought about by mishandling and faulty upbringing, but *not* owing to any fundamental personality defect.
3. Those who have a variety of symptoms, and, owing to either an innate hypersensitivity or an inability to cope with their emotions, over-react to ordinary stresses and strains of life. These are the real “neurotics.”

The degree of incapacity in group 1 is usually proportional to how far the symptoms affect the patient's daily life. Thus, a patient had a phobia of drowning if he entered the sea, but in no way did it affect his daily life in town. Fear of travel clearly is a serious disability which would necessitate treatment in hospital, but otherwise these patients do not need it. Group 2 patients are likely to benefit from psychotherapy; but, unless the communal atmosphere of hospital is considered necessary, they too can perfectly adequately be treated as outpatients. Group 3, being already poorly adapted, removal from their ordinary environment is most undesirable, for many months may elapse before the precarious balance which existed is restored and they are got back to work.

Three groups of psychoneurotics do need admission to hospital: (1) Those who, like my patients described here, are essentially overwrought and overtired, and need a break and a rest, which is best given in a general hospital. (2) Those needing fuller investigation and more specialised treatment than a general hospital can afford. Unless lengthy analytic treatment is to be attempted, I suggest that six weeks is the longest stay that should be aimed at; on admission it should be made clear to the patient that only a short stay is intended, and the whole atmosphere should have a spirit of urgency about it. Unless there are exceptional circumstances, a strict working régime should start at once and be adhered to, with passes out of hospital given only for short periods. Weekend passes are contra-indicated; for, if a patient's conditions warrants being in hospital, it does not warrant his going out at the weekends immediately after admission. (3) A group who at present have to be admitted to hospital owing to lack of therapeutic facilities elsewhere, especially in outlying districts. This group should be, and to some extent is being, gradually eliminated, but it is one having a special bearing on problems of medical man-power and *economic considerations*.

Apart from the clinical aspect, it is economically disadvantageous to treat psychoneurotics as inpatients. A mental hospital with a turnover of 1000 psychoneurotics and psychotics last year cost about £200,000 to run—an average of £200 per patient. According to the Ministry of Health five outpatients can be treated at the cost of one inpatient—i.e., £40 per outpatient in this instance. But psychotherapy requires very little equipment or auxiliary help, and this figure is therefore probably high.

At an outpatient clinic where I hold a weekly session, I saw last year 205 adults and children, and kept two assistants employed on psychotherapy. One assistant treated 30 children and 20 adults in the year, interviews ranging from 2 to 24; the other saw 155 adult old patients, treating 70 of these from 2 to 9 sessions per patient, and giving the others supportive treatment. This example illustrates how individual the number of therapeutic sessions is, and the number of times a patient should be seen is hard to dogmatise about, because it varies so with each therapist. Until there is convincing evidence that its results are so much better than those of shorter methods, psycho-analysis cannot be proposed as a routine treatment, because it takes up so much time.

I should say that a psychotherapist would see a patient on an average 8 times for treatment. On this assumption, if he sees 4 patients per session only, he would treat one patient for the equivalent of a day, and, since there are about 250 working days a year, four therapists of S.H.M.O. grade could see 1000 patients at the cost of about £6800 a year in salaries, plus relatively small overhead expenses.

I believe new psychoneurosis hospitals are being planned, but these calculations, though omitting overheads, show that, with the money needed to run only one such hospital, a substantial, or possibly complete, coverage of psychotherapists for the country could probably be obtained, thus keeping many patients not only out of hospital but also at work. Not only would this save the benefit paid them while they are off work, but it would also prevent loss of earnings and, even more important, loss of work.

This, of course, is not so simple as it sounds; for employers object to employees being away once or twice a week. Education of the employers and the extension of facilities for evening therapeutic sessions could help to meet this situation A difficulty is that to increase facilities creates a further demand At present it is the commendable self restraint of the general practitioner in crowded areas that prevents the swamping of available services, which over enthusiastic salesmanship of psychiatry might well bring about Unfortunately one's appreciation of their forbearance must take the form of referring back untreatable cases, for the attendance of many "chronics" is bad for the morale of new patients (Blacker 1946) Moreover the results of accepting unsuitable cases for psychotherapy only confirm sceptics in their belief of its inefficacy Careful selection, even though it may court temporary unpopularity, will in the end benefit clinics and patients by causing the right type of cases to be referred

I emphasise the need for psychotherapy because in my experience most outpatients needing other than purely supportive treatment require this I have run clinics with very few referrals for E C T , but, lest my view be considered prejudiced, I cite a personal communication from Dr T Munro, who estimated that out of 300 new patients attending Guy's Hospital outpatients department only 6% required E C T When there are not enough facilities for psychotherapy, I am sure there is a tendency —based on a laudable desire to do something for the patients—to use E C T in unsuitable cases, as I have discussed above

SUMMARY AND CONCLUSIONS

Objections to E C T in certain cases is discussed in relation to a small series of cases responding to simple measures in a general hospital

Clinically and economically, it is preferable for psychoneurotic patients to be treated as outpatients Inpatient treatment should be used sparingly, and stay in hospital should be short

I wish to thank Dr W J S Ewan, physician, Dr R Moore, former registrar, and the doctors and nurses of Harold Wood Hospital for all they did for my patients , the improvements recorded were essentially due to their efforts

STREPTOKINASE AS AN ADJUNCT IN THE TREATMENT OF TUBERCULOUS MENINGITIS

JOHN LORBER
M B Camb , M R C P
LECTURER IN CHILD HEALTH, UNIVERSITY OF SHEFFIELD

THERE are many causes of failure in the treatment of tuberculous meningitis, but from the pathological aspect perhaps the most important is the development of obstruction in the cerebrospinal circulation Any method of treatment that would prevent such blocks, or remove them might be of great value

The incidence of these blocks, their distribution, and their detection by the use of penicillin as a tracer substance and by pneumo encephalography have been described elsewhere (Lorber 1950, 1951) Pathological studies show that they are caused by deposition of fibrin and by tuberculous granulation tissue, mostly around the brain stem in the cisterna ambiens, in the cisterns at the base of the brain and round the cord in the spinal subarachnoid space Later the deposit organises into fibrous tissue

Because fibrin is the cause of blocks, Cathie tried the effect of giving streptococcal fibrinolysin intrathecally as an adjunct in the treatment of tuberculous meningitis. He prepared a suitable preparation (Cathie 1949a) of streptokinase, and in a preliminary report (Cathie 1949b) compared his early results in two successive series of cases Series A consisted of 14 children treated with streptomycin alone, of whom only 3 (21%) survived Series B consisted of the next 21 children, treated with both streptomycin and streptokinase, of whom 11 recovered (52%), 2 relapsed after apparent recovery (their fate was not stated), and 8 died But the scheme of intrathecal streptomycin treatment was altered when streptokinase was introduced, and a later publication (Cathie and MacFarlane 1950) disclosed that there were further changes in treatment—namely, the addition of intrathecal 'Sulphetrone' and the frequent use of ventricular catheterisation Moreover, increased experience may have played a large part in the improvement of results The two series therefore were not strictly comparable The only toxic symptom mentioned was a pleocytosis in the cerebrospinal fluid (C S F) similar to that caused by streptomycin

At the time of Cathie's preliminary report, our own results in the treatment of tuberculous meningitis in children showed that there were 4 survivors in our first series of 14 children and 11 in the next series of 21 Streptokinase had not been used The patients were kept under observation for about the same length of time as in Cathie's cases

With these considerations in mind it was decided to conduct a controlled experiment to assess the value of streptokinase

INVESTIGATION

The present investigation was planned to take place during 1950 and to continue only if the results at the end of one year were promising It was decided to use intrathecal streptokinase in half the cases of tuberculous meningitis admitted under the care of the unit during 1950, and cases were chosen at random Of 27 new patients, 2 had already been treated elsewhere for several weeks, and 1 had combined tuberculous and meningococcal meningitis on admission , these 3 were excluded from the investigation Of the remaining 24 bacteriologically confirmed cases, it happened that 12 (group A) were treated with combined intrathecal streptomycin and streptokinase, and 12 (group B) with streptomycin alone In all other respects the treatment was similar in the two groups Routine intrathecal treatment was given by lumbar puncture daily for two periods of twenty one days separated by one week's rest Further intrathecal treatment was given only if the child's condition required it Cisternal and ventricular injections were used as required in cases with spinal blocks Intramuscular streptomycin was given in the usual daily dose of 20 mg per lb body weight for a minimum of six months if the patient survived Intrathecal tuberculin P P D (purified protein derivative), was given to 7 children (3 in group A and 4 in group B), but only after other forms of treatment were thought to have failed With 1 exception, treatment was begun within twenty four hours of admission In 1 child in group A the diagnosis was in doubt for three days and treatment was delayed accordingly A uniform dose of 6 units of streptokinase (Burroughs Wellcome), dissolved in a solution containing streptomycin 25–75 mg , was injected intrathecally daily for as long as was considered necessary This solution was active, in vitro, at room temperature it dissolved the fibrin clot formed in the C S F from cases of tuberculous meningitis, and the dilution was comparable to that obtained in vivo The following remarks will apply only to the commercial preparation which has been used

TABLE I—AGE OF PATIENTS, STAGE OF DISEASE, AND PRESENCE OR ABSENCE OF MILIARY TUBERCULOSIS IN THE TWO GROUPS

Group of patients and treatment given	Age		Stage of disease			Miliary tuberculosis	
	Under 3 years	3 years and over	Early	Intermediate	Advanced	Present	Absent
A (streptomycin and streptokinase)	4	8	2	4	6	5	7
B (streptomycin alone)	4	8	2	4	6	4	8
Total	8	16	4	8	12	9	15

In this investigation there was no selection of patients, and no case was refused admission and treatment. The proportion of advanced cases was very high in both groups. The ages of the children, the stage of the disease at the beginning of treatment (according to the Medical Research Council classification, 1948), and the presence or absence of miliary tuberculosis detected in life, are shown in table I. The two groups were remarkably similar in all respects.

In May, 1950, 14 of the 24 children were alive—7 from group A and 7 from group B. The survivors were observed for six to sixteen months, far too short a time to assess the final results of treatment, but long enough to assess the specific effect of streptokinase, which is the purpose of this paper. The children were investigated by the methods *mentioned elsewhere* (Lorber 1950, 1951) to detect the presence of blocks in the cerebrospinal circulation. Necropsy was performed on 3 of the 5 children in group A who died, and on all 5 children in group B who died.

RESULTS

None of the children had a spinal block on admission. Complete spinal block developed during treatment in 4 of group A and in only 1 of group B. Partial spinal block was detected in 2 children—1 from each group. Of these 7 children with spinal obstruction, 5 died, and in 2 the complete block (1 in each group), and in 1 the partial block, was confirmed at necropsy. These blocks were caused by tuberculous granulation tissue filling the subarachnoid spaces surrounding the spinal cord. Necropsy was not carried out in the 2 other fatal cases. The partial spinal block resolved completely in 1 child who recovered (observation period fifteen months), but complete block persists in another who is otherwise well and whose C.S.F. above the level of the obstruction approached normal. Both these children belonged to group A.

Thus the use of streptokinase in this series was ineffective in preventing the occurrence of spinal blocks in 5 of 12 cases. This proportion of spinal blocks (5 of 12) in group A was not only higher than in group B (2 of 12) but much higher than has previously been observed in cases treated by this unit (Lorber 1950).

Both groups had a high incidence of blocks at the tentorial opening and in the basal cisterns of the subarachnoid space (10 in group A and 9 in group B). This incidence may be attributed to the advanced state of the disease on admission in half the cases (table I), for such blocks are usually present in advanced cases before the start of therapy (Lorber 1951). Cathie and MacFarlane (1950) did not claim that streptokinase will dissolve established blocks, but in this series there was little evidence that it prevented further formation of blocks. In 5 children in the intermediate stage of the disease obstruction was excluded by pneumoencephalography soon after the beginning of treatment. Of these, 3 cases were in group A and all subsequently developed tentorial obstruction. In group B, 1 case later developed such a block. None of the 4 children (2 in each group) who were in the early stage of the disease developed blocks.

NECROPSY FINDINGS

At necropsy, the usual basal exudate was present in 2 of 3 children in group A and in 4 of 5 in group B. In 1 of the cases in group A there was remarkably little exudate to be seen on the base of the brain, but the cisterna ambiens was nevertheless completely obstructed by firm exudate. Of the children in group A who came to necropsy 2 were in the intermediate stage of the disease and showed no evidence of blocks at the beginning of treatment. Thus there was no evidence from the pathological point of view that streptokinase was *beneficial as an adjunct in the treatment of tuberculous meningitis.*

TOXIC EFFECTS

It is difficult to detect the individual toxic effects of drugs given in combination, and also when such toxic effects may closely resemble the signs and symptoms of the disease itself. Possibly for this reason no definite toxic effects were detected in 9 of the 12 children treated with streptokinase. Experience in the investigation and treatment of over 100 cases of tuberculous meningitis had shown that a C.S.F. cell-count of 1000 or even more per c.mm. may occur during intrathecal streptomycin treatment, and that this is not caused by secondary infection. Such a pleocytosis did occur in 2 of the 9 patients in group A. No further investigations were undertaken in these cases.

In the remaining 3 children severe toxic symptoms occurred when streptomycin and streptokinase were given together; 2 of them were early cases and 1 was in the intermediate stage at the beginning of the treatment. In all 3 exceptionally high cell counts were recorded during combined intrathecal treatment. In 2, the count reached 3200 and 4000 white cells per c.mm. In addition there was sustained pyrexia of up to 104°F. The children were listless, irritable, drowsy, and complained of headache. All these symptoms disappeared during the usual week's rest between two courses of intrathecal treatment; the temperature returned to normal and the C.S.F. cell count fell abruptly. The fall is well shown in the extract from the C.S.F. chart of case 1 (table II). This syndrome had been observed in the past with streptomycin treatment alone, though to a *lesser degree. For this reason investigations* were carried out to determine whether these more severe symptoms were due to the streptokinase.

In 2 children who showed these toxic effects during combined treatment, the effect of single intrathecal injections of streptokinase alone was observed on three occasions after intrathecal streptomycin treatment

TABLE II—EXTRACT FROM C.S.F. CHART OF CASE 1

Date	Intrathecal treatment	C.S.F. white-cell count	Culture

STREPTOKINASE AS AN ADJUNCT IN THE TREATMENT OF TUBERCULOUS MENINGITIS

JOHN LORBER
M B Camb , M R C P
LECTURER IN CHILD HEALTH, UNIVERSITY OF SHEFFIELD

THERE are many causes of failure in the treatment of tuberculous meningitis, but from the pathological aspect perhaps the most important is the development of obstruction in the cerebrospinal circulation Any method of treatment that would prevent such blocks, or remove them might be of great value

The incidence of these blocks, their distribution, and their detection by the use of penicillin as a tracer substance and by pneumo encephalography have been described elsewhere (Lorber 1950, 1951) Pathological studies show that they are caused by deposition of fibrin and by tuberculous granulation tissue, mostly around the brain stem in the cisterna ambiens, in the cisterns at the base of the brain and round the cord in the spinal subarachnoid space Later the deposit organises into fibrous tissue.

Because fibrin is the cause of blocks, Cathie tried the effect of giving streptococcal fibrinolysin intrathecally as an adjunct in the treatment of tuberculous meningitis He prepared a suitable preparation (Cathie 1949a) of streptokinase, and in a preliminary report (Cathie 1949b) compared his early results in two successive series of cases Series A consisted of 14 children treated with streptomycin alone, of whom only 3 (21%) survived Series B consisted of the next 21 children, treated with both streptomycin and streptokinase, of whom 11 recovered (52%), 2 relapsed after apparent recovery (their fate was not stated), and 8 died But the scheme of intrathecal streptomycin treatment was altered when streptokinase was introduced, and a later publication (Cathie and MacFarlane 1950) disclosed that there were further changes in treatment—namely, the addition of intrathecal 'Sulphetrone' and the frequent use of ventricular catheterisation Moreover, increased experience may have played a large part in the improvement of results The two series therefore were not strictly comparable The only toxic symptom mentioned was a pleocytosis in the cerebrospinal fluid (C S F) similar to that caused by streptomycin

At the time of Cathie's preliminary report, our own results in the treatment of tuberculous meningitis in children showed that there were 4 survivors in our first series of 14 children and 11 in the next series of 21 Streptokinase had not been used The patients were kept under observation for about the same length of time as in Cathie's cases

With these considerations in mind it was decided to conduct a controlled experiment to assess the value of streptokinase

INVESTIGATION

The present investigation was planned to take place during 1950 and to continue only if the results at the end of one year were promising It was decided to use intrathecal streptokinase in half the cases of tuberculous meningitis admitted under the care of the unit during 1950, and cases were chosen at random Of 27 new patients, 2 had already been treated elsewhere for several weeks, and 1 had combined tuberculous and meningococcal meningitis on admission , these 3 were excluded from the investigation Of the remaining 24 bacteriologically confirmed cases, it happened that 12 (group A) were treated with combined intrathecal streptomycin and streptokinase, and 12 (group B) with streptomycin alone In all other respects the treatment was similar in the two groups Routine intrathecal treatment was given by lumbar puncture daily for two periods of twenty one days separated by one week's rest Further intrathecal treatment was given only if the child's condition required it Cisternal and ventricular injections were used as required in cases with spinal blocks Intramuscular streptomycin was given in the usual daily dose of 20 mg per lb body weight for a minimum of six months if the patient survived Intrathecal tuberculin P P D (purified protein derivative) was given to 7 children (3 in group A and 4 in group B), but only after other forms of treatment were thought to have failed With 1 exception, treatment was begun within twenty four hours of admission In 1 child in group A the diagnosis was in doubt for three days and treatment was delayed accordingly A uniform dose of 6 units of streptokinase (Burroughs Wellcome), dissolved in a solution containing streptomycin 25–75 mg , was injected intrathecally daily for as long as was considered necessary This solution was active, in vitro, at room temperature, it dissolved the fibrin clot formed in the C S F from cases of tuberculous meningitis, and the dilution was comparable to that obtained in vivo The following remarks will apply only to the commercial preparation which has been used

These suggest that streptokinase probably played no part in the good results obtained in the second series of Cathie and MacFarlane (1950)

SUMMARY AND CONCLUSIONS

A controlled investigation was undertaken to determine the value of intrathecal streptokinase as an adjuvant in the streptomycin treatment of tuberculous meningitis, 12 patients being treated with and 12 without streptokinase The two groups were otherwise strictly comparable

Streptokinase appeared to have no effect in reducing the number of blocks occurring during treatment, 5 children developed partial or complete spinal block during treatment in the group treated with streptokinase and streptomycin, and only 2 in the group treated with streptomycin alone, blocks at the tentorial opening or in the basal cisterns developed in 3 patients treated with streptokinase and streptomycin, and in 1 treated with streptomycin alone The necropsy findings in 3 patients treated with streptomycin and streptokinase did not differ from those in patients treated with streptomycin alone

Streptokinase may cause headache, listlessness, drowsiness, vomiting, fever, and a large increase of cells in the cerebrospinal fluid

I wish to thank Prof R S Illingworth for permission to treat and investigate his cases and for his criticism, and Dr J L. Emery for the necropsy reports

INDUCED ASTHMA IN MAN

HERBERT HERXHEIMER
L R C P.E
RESEARCH ASSISTANT, SURGICAL UNIT UNIVERSITY COLLEGE HOSPITAL, LONDON

BRONCHIAL asthma runs a long and varying course, irregularly punctuated by remissions and relapses The causes of this fluctuation often remain obscure. Almost any treatment seems to produce good results so long as it is new and holds the patient's confidence Hurst pointed out in 1943 that desensitisation by means of injections had no greater effect than the injection of physiological saline solution. More recently, Rackemann (1950) found that allergists in the United States achieved equally good results in asthma even when their methods differed fundamentally

It seems certain that emotional or nervous factors play a part in these fluctuations but that other factors contribute in causing them The importance of each factor varies from one patient to another, and even in the same patient from one week to another It is therefore difficult to evaluate the results of treatment Moreover, a high proportion of "psychological" successes is assured whatever treatment is adopted, so that "objective" successes are swamped by them and remain hidden Our aim must be to devise a simple experimental method which will eliminate this difficulty If it was possible to induce mild asthmatic attacks artificially in man and to abort them at will, such an attack would be convenient for investigation and for comparing the effects of various methods of treatment For this purpose we must be able to record the attack graphically from start to finish and to repeat it The method described below seems to fulfil these requirements

METHOD

The patient is connected with an ordinary Benedict-Roth spirometer fitted with a drum for making a continuous record of air movement in the circuit (fig 1) Carbon dioxide is absorbed by a soda lime container fitted outside the spirometer, and a change in the colour of the soda lime indicates when it is saturated with carbon dioxide

The spirometer is filled with atmospheric air An oxygen inlet can be adjusted so that the oxygen used by the patient is replaced at the same rate When this adjustment has been made the mean volume in the spirometer remains constant—i.e, the tracing on the drum remains level, whereas without oxygen replacement the tracing would slope upwards

A side tube from the inspiratory tube leads to a pump which compresses the air and drives it through a glass atomiser back into the inspiratory tube Several glass atomisers, each containing a different liquid, are switched in parallel so that any one of them can be brought into action by opening a clip The pressure of the atomising pump is measured by a manometer in the circuit This arrangement enables the patient's respiration and vital capacity to be recorded on the paper

When this has been done, the pump and one of the atomisers can be switched into the circuit so that the aerosol of some active substance is inhaled, and its effect can thus be observed and recorded.

Disadvantages and Advantages —The chief disadvantage of this method is that the amount of aerosol absorbed by the patient cannot be measured Not all the aerosol is inhaled—some remains in the apparatus—and even that which is inhaled is not all absorbed, since some is pushed back into the circuit during expiration. The dose of aerosol can therefore only be measured on an arbitrary scale and not in absolute values The arbitrary scale used is the duration of the patient's exposure to the aerosol. When the pressure, the atomiser, and the fluid atomised remain the same, the time of exposure is the only measurement that allows a reliable comparison to be made between different experiments A further disadvantage of the method is that it can only be used on patients who can be trained to breathe with the apparatus

There are many advantages The aerosol impinges directly on the effector organ—i e, the bronchus—and does not have to pass through the circulation before acting on it Its effect can thus be recorded as soon as it occurs. When an attack develops its course can be followed, and it may be aborted at any stage by administering aerosol from another nebuliser switched into the circuit In this way the method can be used with complete safety When there is any suspicion that an effect is psychogenic, the experiment can be repeated with another aerosol as control

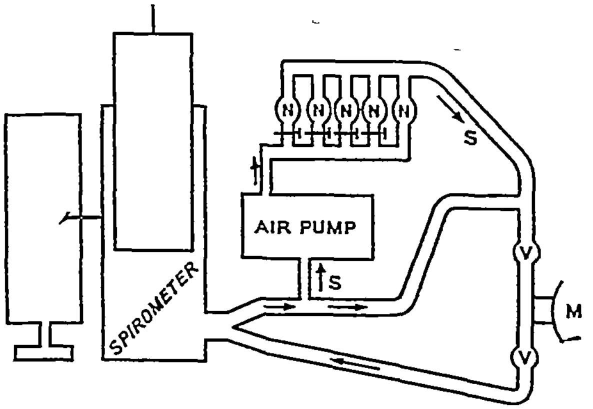

Fig 1—Apparatus for induction of asthmatic attacks S side circuit, attached to inspiratory tube of recording Benedict Roth spirometer contains a pump which takes air from inspiratory tube and drives it out through one of several nebulisers (N) which can be opened or closed by a clip. Aerosol thus produced is carried back into inspiratory tube and inhaled by patient V inspiratory and expiratory valves M mouthpiece.

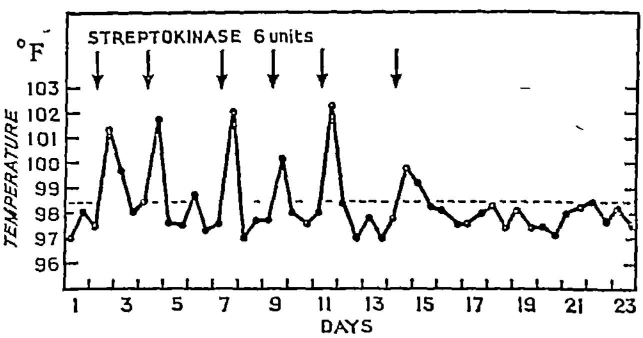

Pyrexial reaction to intrathecal injections of streptokinase in child who had severe toxic symptoms five months before when receiving streptomycin and streptokinase intrathecally

had been stopped In each case enough time was allowed for the C S F cell count to settle to a steady low level (below 200 per c mm) The cell count was done again on the day of streptokinase injection, on the next day, and again after a few days (table II) In each instance there was a rapid rise in the cell count (up to 2400 per c mm), together with fever, vomiting, listlessness, and headache on the evening of the injection All these symptoms disappeared in one to two days and the C S F cell count returned to its previous level Later, the course of the illness made it necessary to start intrathecal streptomycin treatment again in both children This time streptomycin alone was given and no toxic reactions were observed clinically , there was no rise in temperature and the C S F cell count did not rise above 180 per c mm

The 3rd child showed the same toxic symptoms during combined daily intrathecal treatment These symptoms disappeared during a week's rest between courses of treatment In the fifth month of treatment she was given streptokinase intrathecally on three days a week On the days when she had streptokinase she was ill, but on the other days she was alert and playful On the evening of the day of injections she had a high fever, but she was afebrile on other days (see figure)

It seemed, therefore, that in the last 3 children the toxic symptoms were due to the streptokinase, and not to the disease or to the streptomycin

DISCUSSION

It is apparent, that in our hands, and in the doses employed, streptokinase was of no benefit An attempt was made to demonstrate the specific effect of streptokinase in preventing blocks, but no such effect was found In fact blocks developed more often in the cases given streptokinase and streptomycin than in the cases given streptomycin alone, though the difference was not statistically significant Nor was there any difference in the extent and nature of the exudate found in cases which came to necropsy Toxic symptoms were experienced by 3 children, although it was never necessary to interrupt treatment on this account

Towards the end of this investigation a further and fuller account on the use of streptokinase was published by Cathie and MacFarlane (1950) Owing to the multiplicity of factors concerned, which we have mentioned, they found the evaluation of the various therapeutic agents difficult, but considered that " streptokinase has been the most important single factor in the improvement in the second series of cases " This opinion was based on criteria different from those used in the present study There was no direct mention of the occurrence of blocks in their cases, or of their necropsy findings in the 17 patients treated with streptokinase who died No concurrent controls were included in their investigation The claim that streptokinase was of value rested on the observations that the survival rate in the group treated with streptokinase was greater, and the incidence of " increased intracranial pressure " was less Nevertheless, ventricular drainage was necessary in 25 out of 40 cases treated with streptokinase, and in 14 of the 40 (35%) " changes in the flow of the C S F " were considered to be indications for draining the ventricles These last 14 cases probably had partial or complete spinal blocks If so, their incidence of 35% would be very high

The improvement of the results of treatment was the main argument used by Cathie and MacFarlane in favour of streptokinase Their first 14 children were treated without any adjuvants or ventricular drainage and only 2 survived (3 survivors were mentioned in the previous report) The next 6 children were still treated without streptokinase, but the scheme of intrathecal treatment was changed, and the ventricle were drained when necessary Half of these children survived The next 40 children were treated with the altered streptomycin régime and ventricular drainage when considered necessary, but in addition all were treated with streptokinase, and 34 with intrathecal sulphetrone as well. For the evaluation of the results of treatment, only 30 of them can be considered because the observation period of the last 10 was only six to eleven and a half months That a longer period of observation is necessary is shown by Cathie and MacFarlane's own figures Of their first 50 patients, 29 died, and 6 of these (over 20%) died between six and seventeen months after the beginning of treatment This leaves 30 children treated with streptokinase of whom 16, or just over a half, survived. The number of cases is so small that it is not possible to come to any conclusion, but it appears that the improvement in their survival rate may have started with the introduction of the revised intrathecal régime (and ventricular drainage when necessary) before streptokinase was used

All cases were observed for at least a year

As mentioned above greater experience alone, without the addition of adjuvants such as streptokinase, may considerably improve results In our own 67 cases observed for a minimum of one year, 7 of the first 20 survived, whereas of the next 47, despite a much larger proportion of advanced cases, 22 are alive In the very large series of patients treated at Cocchi's clinic at Florence, 13 of the first 57 (23%), 31 of the next 66 (47%), 40 of the next 60 (66%), and 34 of the next 40 (85%) were live after one year's observation (Fiori 1950) In table III are listed for comparison some of the best published results obtained without streptokinase eaction Conversely, in some patients the skin reaction as negative but the bronchial reaction positive

When an aerosol containing an allergen is inhaled by he method described here, there follows a typical reaction hose attributes depend on the nature and amount of he allergen inhaled Experiments of this sort have so ar been carried out with mixed pollens of various kinds, ungi, house dust, cat's fur, horsehair and horse dander, nd meat A characteristic feature of all these experinents, except those done with fungi, is that the attack ever comes on during or immediately after the inhalaion If a moderate attack develops, the first sign appears -3 minutes after the end of the inhalation The vital apacity, which till then has remained unchanged, lecreases a little, but at this stage the patient is usually inaware of the attack, then the attack slowly worsens, nd presently it has to be aborted artificially Such a ypical attack is shown in figs 3 and 5 (curve A)

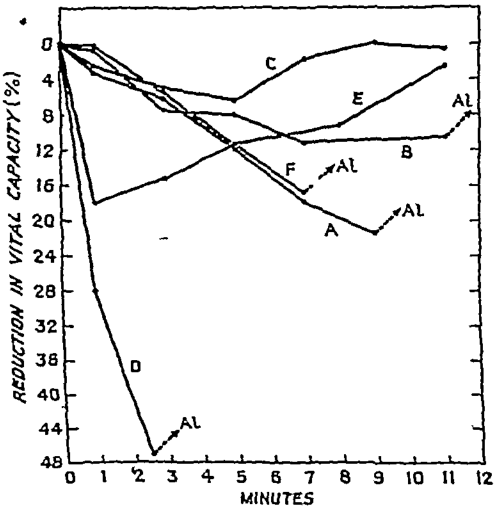

Fig 5—Influence of different types of induced attack of asthma on vital capacity A, decrease of vital capacity in moderate attack B in mild attack C, in very mild attack; D in severe attack all induced by mixed pollen-extract aerosol In A B and C there is hardly any decrease in first minute after inhalation then vital capacity begins to fall and continues to do so until attack is aborted by isoprenaline (AI) Isoprenaline is not necessary in very mild attack (C) which subsides spontaneously In severe attack (D) vital capacity decreases during first minute and attack develops very quickly Attack caused by house-dust antigen (F) is similar to pollen-extract attack. Attack caused by inhalation of mixed mould-extract aerosol (E) is different because it is fully developed a minute after inhalation and subsides spontaneously

If an attack is very mild, the vital capacity diminishes only slightly, remains at this lower level for a while, and finally returns to its normal value (fig 5C) If too much of the allergen is administered, the vital capacity may fall sharply immediately after the inhalation, and when this happens the attack usually becomes unbearable after a few minutes (figs 4 and 5D) Not all patients develop an attack within a few minutes of the inhalation, in some it does not come on for 4–24 hours (" delayed reaction ") This latent period is not related to the dose—it is just as long in mild as in violent reactions

Most attacks induced by fungal allergens are different from those described There is hardly any latent period, and the intensity of the attack is greatest at the end of the inhalation, after that it wanes and often passes off of its own accord Fig 5 illustrates these different types of attack and their effects on vital capacity

Patients vary a good deal in their subjective reaction to an attack Often the patient begins to notice a tightness in his chest only when his vital capacity has fallen 15–20% In other cases the first symptom is a peculiar itching sensation, which comes on early, after about 2 minutes, this may be felt in the neck, the chest, or the upper back, and the patient who feels it is usually familiar with the sensation because it is a feature of his natural asthmatic attacks In other patients a cough is the first sign of the attack, and after it has ended a little sputum is coughed up, but many patients never cough Mould asthma in particular seems to produce coughing It may be that these differences depend not only on the secretion but also on varying involvement of muscle spasm and mucosal œdema Methods for studying the effects of these factors separately have not yet been devised.

The method described here can thus be used to determine whether a given allergen can produce asthma in a particular patient, and if so to reveal the type of the attack The method also enables us to study the action of other asthmogenic substances, such as histamine and acetylcholine It has long been known that asthmatics are much more sensitive to aerosols of histamine and acetylcholine than are normal persons (Samter 1933, Curry 1946, Herxheimer 1949b, 1951) The attack may begin a few seconds after the inhalation The vital capacity may suddenly drop to about half or a third of its initial value These attacks differ from those of allergic asthma in their sudden onset and their greater intensity They begin with their greatest intensity and rarely get worse, after a few minutes the vital capacity begins to rise again, and the attack passes off spontaneously (fig 6)

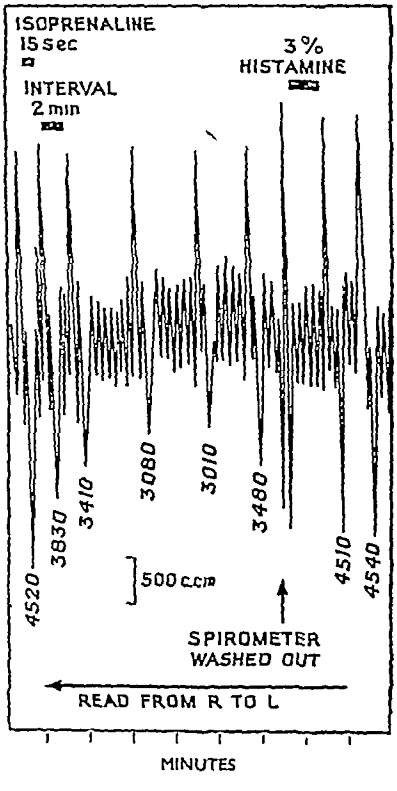

Fig 6—Histamine-induced asthmatic attack in asthmatic patient sensitive to house dust. Vital capacity before attack 4525 c.cm Patient receives 3% *histamine acid phosphate aerosol through breathing circuit after 35 sec. he notices first sign of very mild constriction of chest at this moment he is disconnected from apparatus and spirometer is washed out.* He rapidly becomes breathless and vital capacity a minute after end of inhalation is 3480 c.cm., falling after another minute to 3010 c.cm From now onwards attack gradually subsides and vital capacity increases within 5 min to 3830 c.cm Recovery is hastened by isoprenaline inhalation which brings vital capacity up to normal (3420 c.cm) *Typical for histamine-induced* and acetylcholine-induced attacks are their rapid development, their violence and the frequently spontaneous *recovery inspite of their* severity An allergen-induced attack of similar severity would not subside except after many hours or days.

HYPOSENSITISATION

The inhalation of aerosols can be used in the treatment as well as the diagnosis of allergic states When the tests described here were being carried out it was noted that each patient varied in his reaction to the same dose of aerosol given on different occasions When a certain dose of allergen—e g, 10 seconds' inhalation of a mixed pollen aerosol—provoked a *mild* attack, the same dose given a few days later did not cause an attack Only when the dose was raised by 20–30% was a mild attack produced

Patients who have experienced such an artificial attack of asthma and its dramatic extinction are usually much impressed and readily agree to repeat the experiment Most patients quickly learn to produce reliable records of their vital capacity—i e , their vital capacity varies little from one attempt to another The vital capacity is a useful index of bronchial obstruction, though it does not show up minimal grades of obstruction which can be overcome by voluntary muscle action When necessary, however, these fine degrees can be detected by other methods, which measure the speed of the expiratory outflow

MECHANISM OF THE ATTACK

The artificially induced asthmatic attack enables us to observe its influence on the mechanics of breathing Spirometry shows the movement of air , the movements of the thorax are recorded with Verzár's (1945) thoracograph, and those of the diaphragm are observed radiologically on the screen These methods show that, as soon as expiration is obstructed, air is retained in the thorax This moment can be seen on the spirogram where the tracing moves upwards, since the thorax retains air, the spirometer loses an equal volume of air, and the bell falls to a lower level At the same time the chest circumference increases, and this is shown in the thoracogram On the fluorescent screen one can see that the diaphragm is lowered and reaches its lowest position at the height of the attack

A spirogram and a thoracogram recorded simultaneously (fig 2) show that the transfer of air from the spirometer into the thorax occurs at the same time as the increase in chest circumference Both changes are reversed at the end of the attack, again simultaneously The mechanical effect of such an attack can easily be imitated if the expiratory tube is narrowed with a screw clip The results are similar to those found in the attack, the only difference being in the site of the obstruction (Herxheimer 1949a)

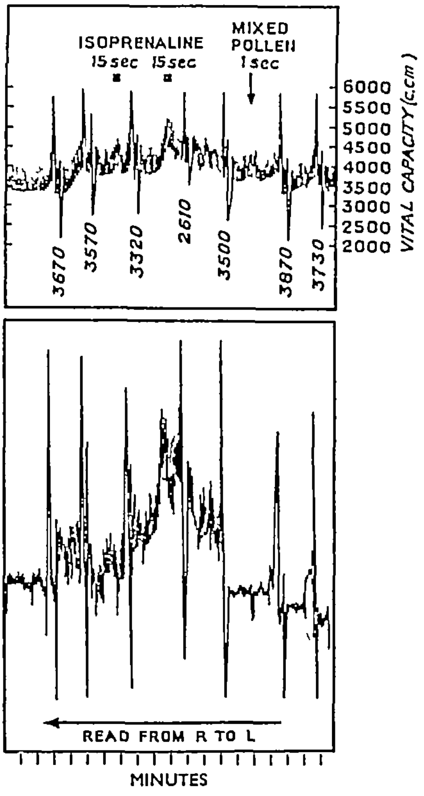

Fig 2—Synchronised spirogram and thoracogram of moderately severe induced asthmatic attack The patient is an asthmatic sensitive to grass pollen She has a basic vital capacity of 3800 c.cm (upper tracing spirogram) and, normally the ribs take little part in the breathing movements in the sitting position (lower tracing thoracogram) She inhales mixed pollen-extract aerosol for 1 sec. A minute later the vital capacity has decreased a little (3500 c.cm) and immediately afterwards the chest circumference increases abruptly (lower tracing) a sign that air is retained in the chest in consequence of incipient expiratory difficulty Two minutes later the attack is well under way the vital capacity is down to 2610 c.cm , and the chest circumference has increased further the spirogram shows an upward trend also indicating retention of air in the thorax and the ribs now move vigorously At this moment isoprenaline aerosol is given to abort the attack. Almost immediately the chest circumference decreases a minute later the vital capacity is 3320 c.cm a little afterwards it is 3760 c.cm almost normal The ribs return to their former relative inactivity Tracings show gradual development of attack and accompanying acute emphysema.

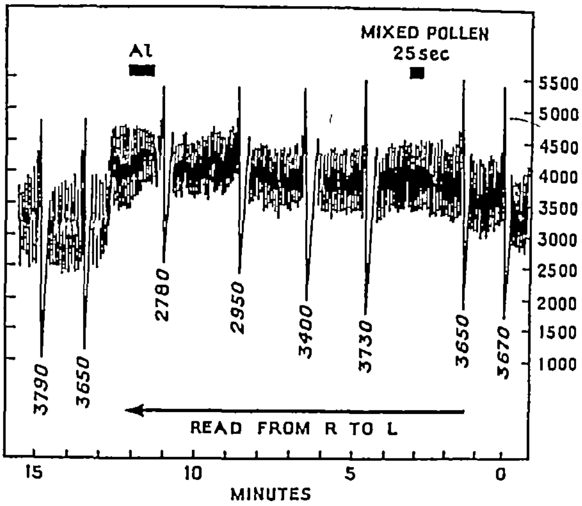

Fig 3—Spirogram of mild asthmatic attack caused by inhalation for 25 sec. of mixed pollen-extract aerosol Vital capacity before attack 3660 c.cm A minute after end of inhalation there is no sign of any attack—vital capacity 3730 c.cm.—but after 2 more minutes attack becomes evident (vital capacity 3400 c.cm) and attack steadily worsens until it reaches a degree of unpleasantness which demands its interruption (vital capacity 2780 c.cm) After a short inhalation of 2% isoprenaline aerosol vital capacity is restored to normal

THE BRONCHIAL REACTION

Until now, hypersensitivity in asthmatic patients has usually been investigated by skin tests However, in allergic hypersensitive states it is unlikely that all the organs are affected equally For this reason many authorities have doubted the value of skin tests in asthma My own experiments with house dust (Herxheimer 1951) showed that among the patients giving a positive skin reaction a high proportion did not give any bronchial

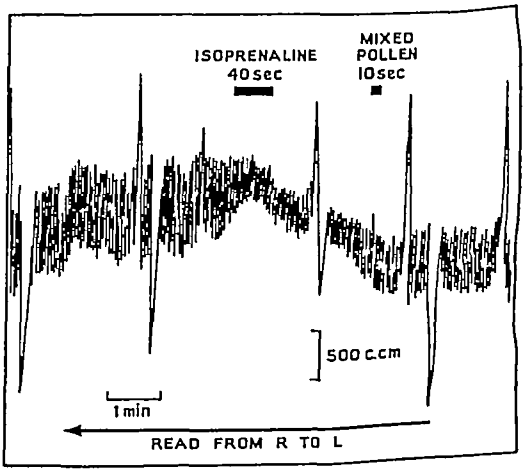

Fig 4—Spirogram of severe asthmatic attack caused by inhalation for 10 sec. of mixed pollen extract. Almost immediately after inhalation the tidal air excursions become smaller air is retained in chest (upward trend of tidal-air level) and after a minute the vital capacity has fallen from 3130 to 1880 c.cm Moderate dyspnœa is now present and it requires 40 seconds inhalation of 2% isoprenaline aerosol to abort the attack. Vital capacity increases to 2730 c.cm , and later to 3000 c.cm An attack of this severity must be expected to increase sensitivity of patient to mixed pollen Note stimulant influence of isoprenaline on respiration : respiratory rate increases from 15 to 18 and tidal air from about 600 to 800 c.cm

action Conversely, in some patients the skin reaction as negative but the bronchial reaction positive

When an aerosol containing an allergen is inhaled by e method described here, there follows a typical reaction hose attributes depend on the nature and amount of e allergen inhaled Experiments of this sort have so r been carried out with mixed pollens of various kinds, ngi, house dust, cat's fur, horsehair and horse dander, nd meat A characteristic feature of all these experi- ents, except those done with fungi, is that the attack ever comes on during or immediately after the inhala- ion. If a moderate attack develops, the first sign appears -3 minutes after the end of the inhalation The vital apacity, which till then has remained unchanged, ecreases a little, but at this stage the patient is usually naware of the attack, then the attack slowly worsens, nd presently it has to be aborted artificially Such a ypical attack is shown in figs 3 and 5 (curve A)

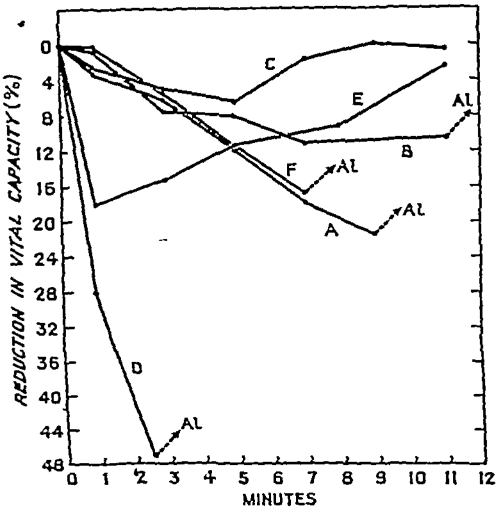

Fig. 5—Influence of different types of induced attack of asthma on vital capacity : A, decrease of vital capacity in moderate attack B in mild attack C, in very mild attack D in severe attack all induced by mixed pollen-extract aerosol In A B and C there is hardly any decrease in first minute after inhalation then vital capacity begins to fall and continues to do so until attack is aborted by isoprenaline (Al) Isoprenaline is not necessary in very mild attack (C) which subsides spontaneously In severe attack (D) vital capacity decreases during first minute and attack develops very quickly Attack caused by house-dust antigen (F) is similar to pollen-extract attack. Attack caused by inhalation of mixed mould-extract aerosol (E) is different because it is fully developed a minute after inhalation and subsides spontaneously

If an attack is very mild, the vital capacity diminishes only slightly, remains at this lower level for a while, and finally returns to its normal value (fig 5C) If too much of the allergen is administered, the vital capacity may fall sharply immediately after the inhalation, and when this happens the attack usually becomes unbearable after a few minutes (figs 4 and 5D) Not all patients develop an attack within a few minutes of the inhalation, in some it does not come on for 4–24 hours ("delayed reaction") This latent period is not related to the dose—it is just as long in mild as in violent reactions

Most attacks induced by fungal allergens are different from those described There is hardly any latent period, and the intensity of the attack is greatest at the end of the inhalation, after that it wanes and often passes off of its own accord Fig 5 illustrates these different types of attack and their effects on vital capacity

Patients vary a good deal in their subjective reaction to an attack Often the patient begins to notice a tightness in his chest only when his vital capacity has fallen 15–20% In other cases the first symptom is a peculiar itching sensation, which comes on early, after about 2 minutes, this may be felt in the neck, the chest, or the upper back, and the patient who feels it is usually familiar with the sensation because it is a feature of his natural asthmatic attacks In other patients a cough is the first sign of the attack, and after it has ended a little sputum is coughed up, but many patients never cough *Mould asthma in particular seems to produce coughing* It may be that these differences depend not only on the secretion but also on varying involvement of muscle spasm and mucosal œdema Methods for studying the effects of these factors separately have not yet been devised.

The method described here can thus be used to determine whether a given allergen can produce asthma in a particular patient, and if so to reveal the type of the attack The method also enables us to study the action of other asthmogenic substances, such as histamine and acetylcholine It has long been known that asthmatics are much more sensitive to aerosols of histamine and acetylcholine than are normal persons (Samter 1933, Curry 1946, Herxheimer 1949b, 1951) The attack may begin a few seconds after the inhalation The vital capacity may suddenly drop to about half or a third of its initial value These attacks differ from those of allergic asthma in their sudden onset and their greater intensity They begin with their greatest intensity and rarely get worse, after a few minutes the vital capacity begins to rise again, and the attack passes off spontaneously (fig 6)

HYPOSENSITISATION

The inhalation of aerosols can be used in the treatment as well as the diagnosis of allergic states When the tests described here were being carried out it was noted that each patient varied in his reaction to the same dose of aerosol given on different occasions When a certain dose of allergen—e g, 10 seconds' inhalation of a mixed pollen aerosol—provoked a *mild* attack, the same dose given a few days later did not cause an attack Only when the dose was raised by 20–30% was a mild attack produced

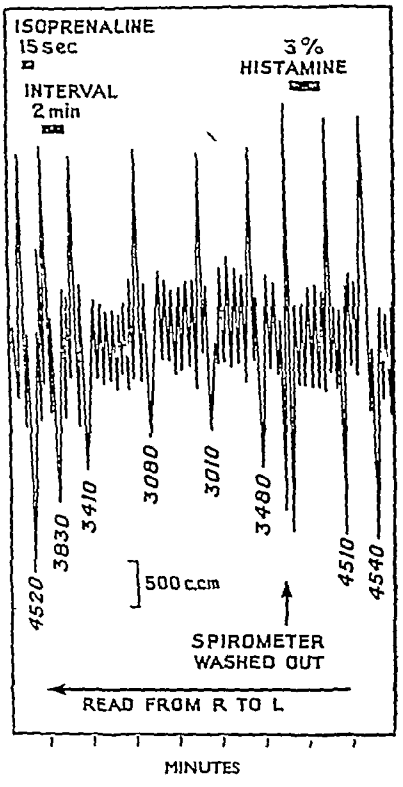

Fig 6—Histamine-induced asthmatic attack in asthmatic patient sensitive to house dust. Vital capacity before attack 4525 c.cm Patient receives 3% histamine acid-phosphate aerosol through breathing circuit after 35 sec. he notices first sign of very mild constriction of chest at this moment he is disconnected from apparatus and spirometer is washed out. He rapidly becomes breathless and vital capacity a minute after end of inhalation is 3480 c.cm falling after another minute to 3010 c.cm From now onwards attack gradually subsides and vital capacity increases within 5 min. to 3830 c.cm. Recovery is hastened by isoprenaline inhalation which brings vital capacity up to normal (3420 c.cm) Typical for histamine-induced and acetylcholine-induced attacks are their rapid development, their violence and the frequently spontaneous recovery inspite of their severity An allergen-induced attack of similar severity would not subside except after many hours or days.

By repeating this process and gradually increasing the dose of allergen inhaled, the patient developed tolerance to it By contrast, when the dose of inhaled allergen was large enough to cause a *severe* attack, the opposite happened and tolerance diminished This became apparent when the dose was considerably reduced —e g , to a third of its previous value This smaller dose now caused an even more severe attack than that caused by the original dose Only a further drastic reduction in the dose led to the desired result, a mild attack

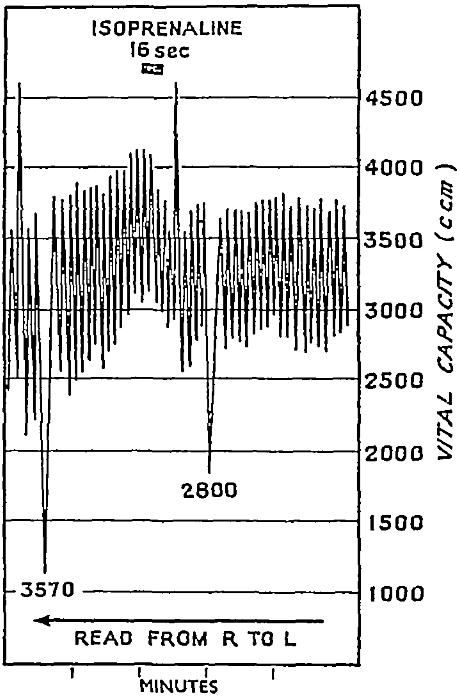

Fig 7—Rapid response of asthmatic attack to isoprenaline inhalation Pollen-induced attack in asthmatic patient sensitive to grass pollen Almost immediately after end of 16 seconds inhalation of isoprenaline tidal air increases considerably (from about 900 c.cm to about 1200 c.cm) A minute later vital capacity has increased from 2800 to 3570 c.cm Increase is entirely due to increase of reserve air some of which, during attack could not be exhaled and therefore formed part of residual air

These phenomena are evidently instances of hyposensitisation and hypersensitisation Large doses increase, and small doses diminish, the patient's sensitivity to the allergen concerned If this observation is correct, it must be possible to hyposensitise patients by using small and gradually increasing doses (this used to be called desensitisation) This has been done in some cases (Herxheimer 1951) For instance, in a patient who developed a mild attack after 8 seconds' inhalation when treatment was begun, the tolerance was so increased that three months later 100 seconds' inhalation had no effect In the first two cases of grass pollen asthma treated in this way the asthma did not appear the following summer, though oddly enough the ocular and nasal symptoms persisted in part

These observations may be of both theoretical and practical significance If it is possible to intensify or to weaken the allergic reaction of the bronchial tree in this way, the question arises whether similar processes may not occur in the daily life of asthmatics An excessive amount of allergen inhaled accidentally—e g , house dust in moving house, and grass pollen on outings in the country—would make the asthma worse and hypersensitise the patient, who now would respond severely even to doses which previously did not injure him Only after he has returned to his usual surroundings may the amount inhaled become *very* much smaller, in these circumstances the asthma improves very gradually and reverts to its usual intensity In some asthmatics it seems as if such episodes of hypersensitisation and hyposensitisation occur quite often When one tries to discover why a chronic asthmatic suddenly becomes worse one sometimes finds that shortly before the attack the patient had exposed himself to a gross overdose of "his" allergen Often such an event cannot be recognised with certainty

Factors which are not allergic also play a part Excitement from any cause, and physical exertion, can greatly increase the ventilation Under these conditions the amount of allergen inhaled may be increased to many *times its usual value for purely mechanical* reasons, and this alone may cause considerable "overdosage" of allergen

The practical importance of our observations lies in the *fact that the treatment of allergic asthma* can be put on a much firmer basis than hitherto Hyposensitisation by injection does not allow precise observation of its progress. When a patient shows a systemic reaction, this is usually regarded as a sign of overdosage When there is no reaction, it is tacitly assumed that hyposensitisation is being achieved Final success is seldom conclusively proved It can only be regarded as proved if the patient does not react on exposure to the original allergen and has had no other treatment This occurs in only a very few cases

The inhalation method has many advantages The progress of hyposensitisation can be observed directly, and the dose of allergen may be raised in such a way that the patient's reaction to it is always the same. This is of particular importance since it may be very difficult to avoid the inhalation of allergen from natural sources. It may easily happen that the dose of allergen aerosol given therapeutically is added on to an unknown dose inhaled unwittingly If the latter is large, an overdose at the controlled inhalation will be inevitable, but the severity of the attack will indicate how much the dose should be reduced at the next inhalation It is easier to carry out hyposensitisation in an allergen free environment, but in practice this is only possible when the allergen is strictly seasonal

Another difficulty which demands continuous and objective control of the process of hyposensitisation is caused by acute respiratory infections If such an intercurrent infection develops during treatment, the

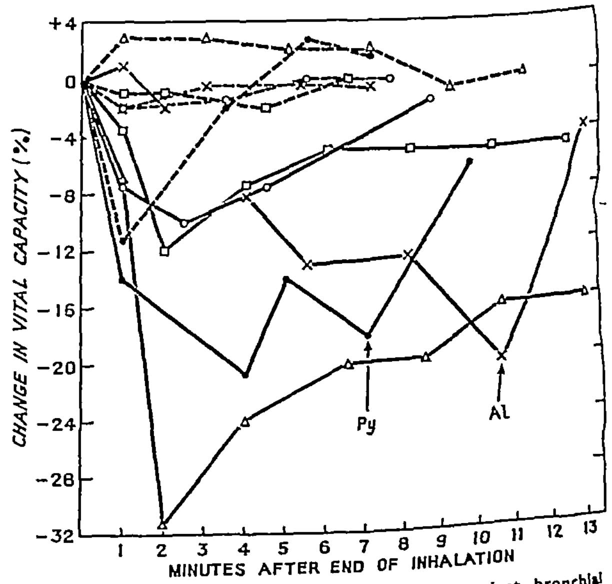

Fig 8—Protective action of anti histamine drug against bronchial asthma induced by inhalation of mixed pollen in 5 patients solid lines change in vital capacity after inhalation without protection ; interrupted lines change in vital capacity after various doses of phenergan had been given beforehand.

Py, pyribenzamine 1 5% and Al aleudrine 1% inhaled to end the asthmatic attack (Herxheimer 1949b)

patient's tolerance usually decreases A dose of allergen which did not evoke a reaction before the illness may now produce a severe reaction The common occurrence of acute respiratory infections makes it inevitable that the treatment is upset in a good many cases Apart from this, many asthmatics are sensitive to many different allergens which cannot be removed from their everyday environment They are inhaled in varying amounts and necessarily disturb any attempt at hyposensitisation, often preventing it completely This state of affairs is quickly recognised when the inhalation method is being used, with the injection method several unexplained setbacks often occur before the procedure is seen to be fruitless.

EFFECT OF DRUGS

A further field in which the inhalation method is useful is the study of drug action. The effect of anti-asthmatic drugs—e g, adrenaline, isoprenaline, and the anti-histamine drugs—can be measured objectively when they act on an induced attack Thus it can be shown that isoprenaline aerosol acts almost instantaneously (fig 7) Adrenaline and isoprenaline will suppress almost any attack if the dose is big enough, but this is not true of the anti histamine drugs These latter drugs are entirely unsuitable for the treatment of an acute attack They will, however, prevent a mild attack if given some time before the induction of the attack is attempted (Herxheimer 1949b), the dosage required varies considerably in different patients (fig 8) Even large doses will not protect the patient from moderate and severe attacks

This method of assessing the protective action of drugs has also been used successfully by Rubitsky et al. (1949) The results are particularly useful in comparing the efficacy of one drug with that of others.

SUMMARY

A method is described for inducing asthmatic attacks by means of aerosol inhalations of allergenic extracts and other substances

The narrowing of the bronchial lumen and its effect on the mechanics of breathing in these attacks can be demonstrated graphically

The attack can be terminated at any stage by giving an inhalation of isoprenaline.

Sensitivity of the bronchial tree to asthmogenic substances can be demonstrated more reliably by this method than by skin tests

The sensitivity of the bronchial tree to allergens can be increased by giving large doses and decreased by giving small doses.

The reactions of different patients to the same allergen vary in severity, in latent period, and possibly in the degree to which muscle spasm and mucosal œdema and secretion play a part in their production

Aerosol inhalations can be used to reduce sensitivity Their main advantage over the injection method is that they allow progress to be observed objectively In many cases such hyposensitisation is impossible because the influence of exogenous allergens cannot be excluded.

The inhalation method can also be used to compare the anti asthmatic activity of drugs.

I am indebted to Dr Andrew Morland for access to some of the patients.

PRIMARY HYDROCELE AND ITS TREATMENT

REVIEW OF TWO HUNDRED CASES

D P Burkitt
M.D Dubl., F.R C.S.E
MEDICAL OFFICER, UGANDA

In the district of Lango, in Uganda, hydrocele is very common Its incidence over large areas exceeds 25% of the adult male population, varying geographically from 30% in the east to 1% in the west

The size of the hydrocele sacs is immense, the average content of one sac being a little over a pint In examining just over 300 cases I found bilateral hydroceles in 43% In 8% the content of fluid in one sac exceeded three pints The largest was a bilateral hydrocele with ten pints in one sac and thirty-four fluid ounces in the other

The classification of hydroceles into "vaginal" and "infantile" is fallacious, because in time most hydroceles stretch up to or near to the internal abdominal ring

Of the 3 abdominoscrotal hydroceles seen, 1 closely resembled clinically an enormously distended bladder associated with a right hydrocele. It contained six pints of fluid, of which five pints were in the intra-abdominal portion The other 2 contained about six ounces in the intra abdominal portion An abdominal hydrocele containing thirty four ounces of fluid was also treated there was no communication with a concomitant right vaginal hydrocele, though a process entered the inguinal canal and reached almost to the apex of the vaginal hydrocele

True bilocular hydroceles were rare when the hydrocele was large, for the waist tended to disappear with distension. A bilocular appearance was found with the epididymis as a belt forming the waist

About 8% of scrotal swellings were due to hæmatoceles, usually in elderly men

By virtue of their size and number hydroceles in Lango district are responsible for a great deal of disability, preventing work In addition, with the larger hydroceles, the disappearance of the penis is a complete bar to reproduction

TREATMENT

Our aim has been to combine efficiency with simplicity and economy in time, materials, and hospital accommodation Three possible lines of treatment have been advocated—simple tapping, tapping followed by the introduction of sclerosing agents, and radical operation

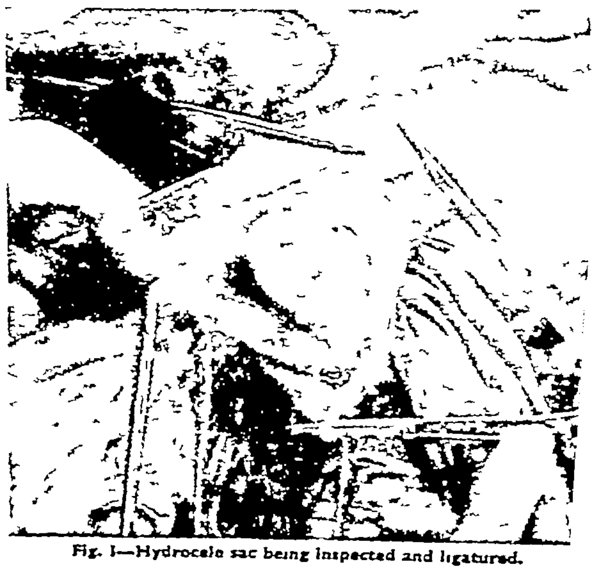

Fig. 1—Hydrocele sac being inspected and ligatured.

By repeating this process and gradually increasing the dose of allergen inhaled, the patient developed tolerance to it By contrast, when the dose of inhaled allergen was large enough to cause a *severe* attack, the opposite happened and tolerance diminished This became apparent when the dose was considerably reduced —e g , to a third of its previous value This smaller dose now caused an even more severe attack than that caused by the original dose Only a further drastic reduction in the dose led to the desired result, a mild attack

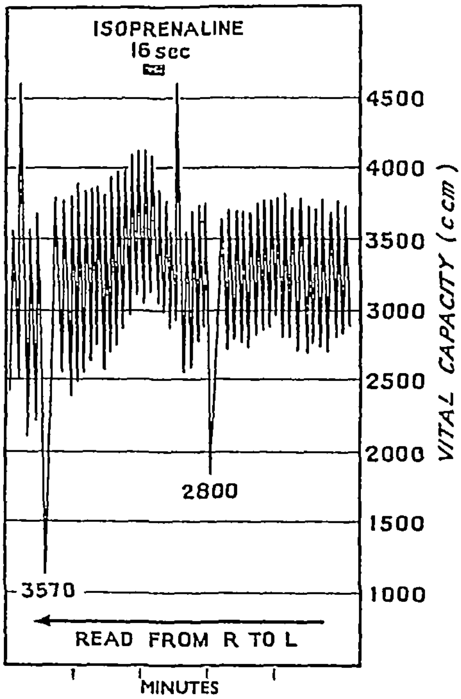

Fig 7—Rapid response of asthmatic attack to isoprenaline inhalation Pollen induced attack in asthmatic patient sensitive to grass pollen Almost immediately after end of 16 seconds inhalation of isoprenaline tidal air increases considerably (from about 900 c.cm to about 1200 c.cm) A minute later vital capacity has *increased from 2800 to 3570 c.cm Increase is* entirely due to increase of reserve air some of which, during attack, could not be exhaled and therefore formed part of residual air

These phenomena are evidently instances of hyposensitisation and hypersensitisation Large doses increase, and small doses diminish, the patient's sensitivity to the allergen concerned If this observation is correct, it must be possible to hyposensitise patients by using small and gradually increasing doses (this used to be called desensitisation) This has been done in some cases (Herxheimer 1951) For instance, in a patient who developed a mild attack after 8 seconds' inhalation when treatment was begun, the tolerance was so increased that three months later 100 seconds' inhalation had no effect In the first two cases of grass-pollen asthma treated in this way the asthma did not appear the following summer, though oddly enough the ocular and nasal symptoms persisted in part

These observations may be of both theoretical and practical significance *If it is possible to intensify or to* weaken the allergic reaction of the bronchial tree in this way, the question arises whether similar processes may not occur in the daily life of asthmatics An excessive amount of allergen inhaled accidentally—e g , house dust in moving house, and grass pollen on outings in the country—would make the asthma worse and hypersensitise the patient, who now would respond severely even to doses which previously did not injure him Only after he has returned to his usual surroundings may the amount inhaled become *very* much smaller , in these circumstances the asthma improves very gradually and reverts to its usual intensity In some asthmatics it seems as if such episodes of hypersensitisation and hyposensitisation occur quite often When one tries to discover why a chronic asthmatic suddenly becomes worse one sometimes finds that shortly before the attack the patient had exposed himself to a gross overdose of " his " allergen Often such an event cannot be recognised with certainty

Factors which are not allergic also play a part Excitement from any cause, and physical exertion, can greatly increase the ventilation Under these conditions the amount of allergen inhaled may be increased to many times its usual value for purely mechanical reasons, and this alone may cause considerable " overdosage " of allergen

The practical importance of our observations lies in the fact that the treatment of allergic asthma can be put on a much firmer basis than hitherto Hyposensitisation by injection does not allow precise observation of its progress. When a patient shows a systemic reaction, this is usually regarded as a sign of overdosage When there is no reaction, it is tacitly assumed that hyposensitisation is being achieved Final success is seldom conclusively proved It can only be regarded as proved if the patient does not react on exposure to the original allergen and has had no other treatment This occurs in only a very few cases

The inhalation method has many advantages The progress of hyposensitisation can be observed directly, and the dose of allergen may be raised in such a way that the patient's reaction to it is always the same. This is of particular importance since it may be very difficult to avoid the inhalation of allergen from natural sources. It may easily happen that the dose of allergen aerosol given therapeutically is added on to an unknown dose inhaled unwittingly If the latter is large, an overdose at the controlled inhalation will be inevitable, but the severity of the attack will indicate how much the dose should be reduced at the next inhalation It is easier to carry out hyposensitisation in an allergen free environment, but in practice this is only possible when the allergen is strictly seasonal

Another difficulty which demands continuous and objective control of the process of hyposensitisation is caused by acute respiratory infections If such an intercurrent infection develops during treatment, the

Py, pyribenzamine 1 5%, and Al aleudrine 1% inhaled to end the asthmatic attack (Herxheimer 1949b) distinguishing between persistent emboli and thrombosis in situ, and regards the history of embolic incidents as all important in this respect It seems possible, however, that many of the cases described at necropsy as examples of pulmonary artery thrombosis may actually represent the result of former emboli, since an unexplained or "primary" thrombosis in such a situation is less easy to understand Carroll (1950) and Belt (1939) suggest that some cases diagnosed as Ayerza's syndrome may have a like origin The reason why these emboli persist whereas others disappear does not seem to be established. In the present case there seems little doubt that the original obstructions suffered recurrent additions to their substance, and, had the cause of the dyspnœa been understood, ligature of the veins would have been an obvious measure The point to be emphasised is that chronic heart failure does arise in this manner

DELAYED EFFECTS OF ULTRAVIOLET BURNS IN MAN

M L THOMSON
M.B Glasg
SENIOR LECTURER, APPLIED PHYSIOLOGY DEPARTMENT,
LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

It was widely believed in the past that the sun's rays, by damaging the brain or the spinal cord, could cause pyrexia, delirium, coma, and death Aron (1911) showed that death in monkeys exposed to tropical sunlight was caused solely by a general rise in body temperature It has now been established that the biologically active ultraviolet (U V) portion of the sun's rays does not penetrate more than 1 or 2 mm into the skin, hence the possibility of direct injury to the nerve centres may be excluded It is now fashionable to regard the sun's rays as exerting no specific effect on man's ability to tolerate heat (Blum 1945) It has been shown, however, that after exposure to U V radiation there may be a reduction in sweating rate which is partly caused by occlusion of the mouths of sweat gland ducts in the necrosed surface layer of the epidermis, and probably partly by reduction of secretory pressure of sweat (Thomson 1951a and b) I report here the collapse, apparently attributable to previous U V radiation, of two men working in a heated room, and the development of sun blisters in another case

METHODS

The two men (Ha and Al) were fit young naval ratings who had previously been acclimatised by fourteen days' daily exposure to heat They worked and rested intermittently according to the same routine for four hours during all trials in the climatic chamber They were weighed nude and their rectal temperatures and pulse rates were taken at short intervals throughout each trial. Shorts and plimsolls were worn, and these were weighed separately before and after each trial The men's adjusted loss of weight was taken as a sufficiently accurate measure of their sweat-loss (sweat = loss of weight + fluids − excreta) The environmental conditions during all trials were as follows dry bulb temperature 115°F, wet-bulb temperature 85°F, air movement 200 ft per min (91°F effective temperature)

Radiation —On May 0, in the course of other trials conducted under identical conditions, one of the two men (Ha) chanced to expose his skin for four hours to uninterrupted sunshine while wearing bathing trunks On May 10 severe erythema was noted on his shoulders, chest, thighs and arms Ten days later (May 25) he and Al were both deliberately exposed to a standard mercury vapour U V lamp Two or three hours later both men developed a strong erythema Before radiation on May 28 sudamina was observed on Ha Al had papules at the sweat duct openings and itching on exposure to heat

RESULTS

Rectal temperatures and standing pulse rates (fig 1) are shown for the trials on May 25, 26, 27, and 28 for both men, and on May 10 and 24 for Ha Sweat losses (see table) on post radiation days were lower than on control days, but the difference was only significant in the case of Ha on the day of collapse (May 10) On the other hand, sweat in clothes fell appreciably after radiation as this table shows

TOTAL SWEAT LOSS AND SWEAT IN CLOTHING

Date of trial		May 10	May 24	May 25	May 26	May 27	May 28
Total sweat (g)	Ha	(1096)*	1356	1320	(1285)	1285	1310
	Al			1120	(1100)	1075	1210
Increase in weight of shorts (g)	Ha	(18)	40	62	(12)	6	58
	Al			13	(−6)	4	10

* Significant at 1 % level In parentheses one day after radiation.

The criteria of collapse in the heat were (1) a rectal temperature higher than 101 2°F, (2) a high pulse rate for the man, (3) muscular weakness, (4) evidence of postural hypotension (giddiness, faintness), (5) the men's statement that they could no longer carry on (viewed in the light of their known grit and reliability), and (6) the observers' estimate of the men's condition

On the day after the first exposure to U V radiation both men collapsed under environmental conditions which they had borne without undue discomfort on control days and are known to be readily withstood by fit acclimatised young men

In the case of Ha the first exposure to sunlight on May 9 was followed by collapse on May 10, in the case of Al the only exposure was to U V lamp on May 25 and was followed by collapse on May 26 Ha did not collapse after U V lamp treatment on May 25, and it may be presumed that the previous acute sunburn had partially protected him against the effects of the lamp (Thomson 1951b) Nevertheless this man showed a higher rectal temperature and pulse rate and lower terminal sweat loss on May 26 than on any other day except May 10, so the protection conferred by the earlier exposure does not seem to have been complete

COR PULMONALE FROM RECURRENT PULMONARY EMBOLISM

C P PETCH
M.D Camb, M R C P
CONSULTANT PHYSICIAN, ST HELIER HOSPITAL, CARSHALTON

CHRONIC cor pulmonale, or pulmonary heart disease, indicates hypertrophy or failure of the right side of the heart due to disease of the lungs or of the pulmonary arteries Acute cor pulmonale denotes the state of the heart immediately after the arrival of large emboli in the pulmonary artery, and usually, if this is not fatal, recovery is rapid It has long been observed, however, that recovery after non fatal embolism is not always complete, and the development of chronic cor pulmonale as a result of persistent or recurrent emboli is possible (Ljungdahl cited by Friedberg 1949) The chronic form here arises as a consequence of the acute This sequence of events has usually been reported by pathologists from necropsy findings (Belt 1939, Castleman and Bland 1946) and has received little recognition clinically, the following case might well have been diagnosed in life had the picture been familiar

CASE RECORD

A labourer, aged 46, previously free from serious disease of heart or lungs, was admitted to hospital on July 15, 1949, for repair of a right inguinal hernia The operation was uneventful, but fourteen days later the patient developed a sudden pain in the right lower chest posteriorly, with pleural friction, hæmoptysis, and pyrexia The legs were not tender or swollen Radiography of the chest showed consolidation at the right base Penicillin and sulphamezathine were given, and, a little later, a ten day course of heparin intravenously In spite of this, five weeks after the operation, on Aug 20, the patient experienced a similar sudden pain in the left side of the chest and was transferred to a medical ward At the time of transfer his pain had subsided and his main complaint was shortness of breath

On examination he had no fever, a blood pressure of 95/60 mm Hg, and bilateral basal crepitations in the lungs without signs of consolidation Electrocardiography on Sept 1 showed a well marked S wave in all leads, with steep inversion of TII and TIII (fig 1) This was regarded as compatible with acute

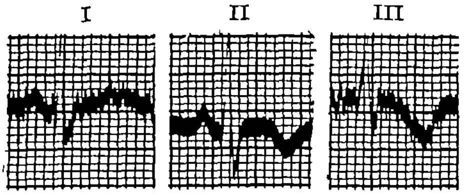

Fig 1—Electrocardiogram on Sept. 1 1949

cor pulmonale due to the episodes of pulmonary embolism already described Auricular fibrillation was observed for two days, but sinus rhythm, confirmed electrocardiographically, returned after the administration of quinidine and persisted until death

Progress—A third attack of pain, this time in the right chest, with shortness of breath and slight staining of the sputum, developed on Sept 13, 1949, but a week later the patient was free from abnormal physical signs and well enough to go to a convalescent home During the autumn and winter he attended as an outpatient, and reported that he could work a little as a labourer, but was gradually becoming incapacitated by shortness of breath He also complained of a rather persistent, not episodic, pain in the chest Clinical examination did not reveal any adequate cause for these symptoms A radiograph of the chest was clear, and electrocardiography on Dec 12 showed restoration of an upright T wave in all leads (fig 2) In retrospect it seems that the pulmonary artery was being partly occluded The patient's condition on May 1, 1950, was so bad that he was readmitted to hospital He had had more severe attacks of chest pain, and both ankles had begun to swell

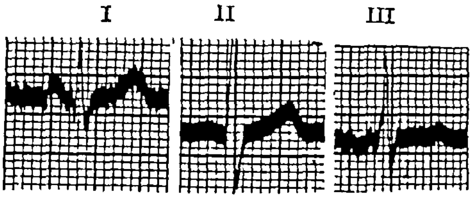

Fig 2—Electrocardiogram on Dec 12, 1949

On examination he had cyanosis, jugular venous stasis, a tender liver, and dependent œdema, he had no fever, his pulse was regular, pulse rate 80, and blood pressure 100/70 mm Hg The pulmonary second sound was loud, and protodiastolic triple rhythm was present, but signs in the lungs were minimal Electrocardiography on May 3 showed a right bundle branch block pattern, in the standard limb leads P waves were tall, and a peaked "pulmonary" P wave was present in lead II (fig 3)

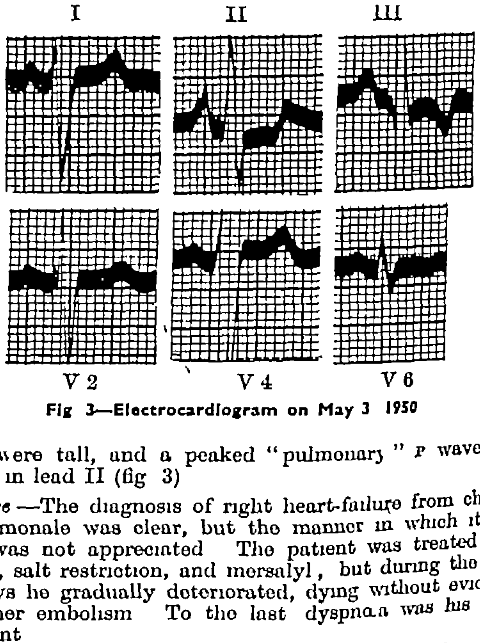

Fig 3—Electrocardiogram on May 3 1950

Course—The diagnosis of right heart-failure from chronic cor pulmonale was clear, but the manner in which it had arisen was not appreciated The patient was treated with heparin, salt restriction, and mersalyl, but during the next five days he gradually deteriorated, dying without evidence of further embolism To the last dyspnœa was his chief complaint

Necropsy Findings (Dr T Goodier)—The larger branches of the pulmonary artery on both sides were found to be filled with organised blood clot of different ages The right side of the heart was much hypertrophied and dilated, the tricuspid valve admitting five fingers No septal defect was found, the left side of the heart was normal, without valvular lesion or scar of the myocardium and the coronary arteries were patent The liver showed intense passive congestion. In the right popliteal vein were the remains of a long ante-mortem thrombus arising from the veins of the calf Fragments of this thrombus had presumably formed the emboli that had blocked the pulmonary vessels and caused death from right heart failure

COMMENT

Carroll (1950) could only find three published reports of what was unquestionably chronic obstruction of the pulmonary artery arising from embolism He added four of his own, with histories very similar to the one described here Like earlier workers he alludes to the difficulty of

DELAYED EFFECTS OF ULTRAVIOLET BURNS IN MAN

M L Thomson
M.B Glasg

SENIOR LECTURER, APPLIED PHYSIOLOGY DEPARTMENT,
LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

It was widely believed in the past that the sun's rays, by damaging the brain or the spinal cord, could cause pyrexia, delirium, coma, and death Aron (1911) showed that death in monkeys exposed to tropical sunlight was caused solely by a general rise in body temperature It has now been established that the biologically active ultraviolet (U V) portion of the sun's rays does not penetrate more than 1 or 2 mm into the skin, hence the possibility of direct injury to the nerve centres may be excluded It is now fashionable to regard the sun's rays as exerting no specific effect on man's ability to tolerate heat (Blum 1945) It has been shown, however, that after exposure to U V radiation there may be a reduction in sweating rate which is partly caused by occlusion of the mouths of sweat gland ducts in the necrosed surface layer of the epidermis, and probably partly by reduction of secretory pressure of sweat (Thomson 1951a and b) I report here the collapse, apparently attributable to previous U V radiation, of two men working in a heated room, and the development of sun blisters in another case

METHODS

The two men (Ha and Al) were fit young naval ratings who had previously been acclimatised by fourteen days daily exposure to heat They worked and rested intermittently according to the same routine for four hours during all trials in the climatic chamber They were weighed nude, and their rectal temperatures and pulse rates were taken at short intervals throughout each trial Shorts and plimsolls were worn, and these were weighed separately before and after each trial The men's adjusted loss of weight was taken as a sufficiently accurate measure of their sweat-loss (sweat = loss of weight + fluids − excreta) The environmental conditions during all trials were as follows dry bulb temperature 115°F, wet-bulb temperature 85°F, air movement 200 ft per min. (91°F effective temperature)

Radiation —On May 9, in the course of other trials conducted under identical conditions, one of the two men (Ha) chanced to expose his skin for four hours to uninterrupted sunshine while wearing bathing trunks On May 10 severe erythema was noted on his shoulders, chest, thighs and arms Ten days later (May 25) he and Al were both deliberately exposed to a standard mercury vapour U V lamp Two or three hours later both men developed a strong erythema. Before desquamation on May 28 sudamina was observed on Ha. Al had papules at the sweat duct openings and itching on exposure to heat

RESULTS

Rectal temperatures and standing pulse rates (fig 1) are shown for the trials on May 25, 26, 27, and 28 for both men, and on May 10 and 24 for Ha Sweat losses (see table) on post radiation days were lower than on control days, but the difference was only significant in the case of Ha on the day of collapse (May 10) On the other hand, sweat in clothes fell appreciably after radiation as this table shows

TOTAL SWEAT LOSS AND SWEAT IN CLOTHING

Date of trial		May 10	May 24	May 25	May 26	May 27	May 28
Total sweat (g)	Ha.	*(1096)**	1356	1320	(1285)	1285	1310
	Al			1120	(1100)	1075	1210
Increase in weight of shorts (g)	Ha	(18)	40	62	(12)	6	58
	Al			13	(−6)	4	10

* Significant at 1 % level In parentheses one day after radiation.

The criteria of collapse in the heat were (1) a rectal temperature higher than 101 2°F, (2) a high pulse rate for the man, (3) muscular weakness, (4) evidence of postural hypotension (giddiness, faintness), (5) the men's statement that they could no longer carry on (viewed in the light of their known grit and reliability), and (6) the observers' estimate of the men's condition

On the day after the first exposure to U V radiation both men collapsed under environmental conditions which they had borne without undue discomfort on control days and are known to be readily withstood by fit acclimatised young men

In the case of Ha the first exposure to sunlight on May 9 was followed by collapse on May 10, in the case of Al the only exposure was to U V lamp on May 25 and was followed by collapse on May 26 Ha did not collapse after U V lamp treatment on May 25, and it may be presumed that the previous acute sunburn had partially protected him against the effects of the lamp (Thomson 1951b) Nevertheless this man showed a higher rectal temperature and pulse rate and lower terminal sweat loss on May 26 than on any other day except May 10, so the protection conferred by the earlier exposure does not seem to have been complete

IN-VIVO SURVIVAL OF RABBIT'S RED CELLS RECOVERED AFTER FREEZING

H A SLOVITER*
M D, Ph D Pennsylvania
om the National Institute for Medical Research, Mill Hill, London

It was recently reported (Smith 1950) that blood uted with a glycerol solution can be frozen, kept at 79°C, and subsequently thawed without producing ore than slight hæmolysis Human red blood cells treated can be recovered in yields of 80–90% of their ginal number (Sloviter 1951), these recovered red lls are normal in appearance, and their behaviour in ro suggests that they are capable of normal function

The present study was undertaken to determine whether bbit red blood cells recovered after freezing survive ien they are injected into the circulating blood eam The procedure used for this purpose was to bel, with a radioactive isotope, the cells which had been ozen and recovered, and to determine the radioactivity naining in the circulating red blood cells at various nes after placing the labelled cells into the circulation

The rabbit was chosen for these experiments, for two sons (1) the rabbit is a convenient animal for this rpose, and (2) the red blood cells of the rabbit are nost as permeable to glycerol as human red blood lls (Jacobs et al 1935)

The isotope used in most of these experiments was dioactive phosphorus (P^{32}) Labelling of the red ood cells with P^{32} and measurement of their radio tivity were carried out in a manner similar to that scribed by Reeve and Veall (1949) Radioactive romium (Cr^{51}) was also used because it remains in the d blood cell longer and has a longer half life than es P^{32} On these grounds, it was expected that Cr^{51} periments would yield more conclusive results Unfor nately, Cr^{51} was available only in low specific activity aterial, and the results were not sufficiently precise ells were labelled with Cr^{51} and radioactivity measured cording to the technique described by Gray and erling (1950)

METHOD

A 5 ml portion of rabbit blood, to which acid citrate xtrose anticoagulant had been added, was mixed with an ual volume of glycerol solution (30 g glycerol and 0 85 g dium chloride per 100 ml) About one hour after mixing, ch samples were immersed in a solid carbon dioxide alcohol th (−79°C) and then kept at −79°C in sealed tubes for up 42 days After thawing, the red blood cells were recovered, the manner previously described for human red blood lls (Sloviter 1951) and were then suspended in an equal lume of 0 85% sodium chloride solution To this suspension as added approximately 30 microcuries of P^{32} (as sodium

THE LANCET

LONDON SATURDAY, JUNE 23, 1951

Paying Paul

At its annual meeting last week the Representative Body of the British Medical Association heard from Dr Wand, chairman of the General Medical Services Committee, a report on the progress of negotiations for improving general practitioners' remuneration. It will be recalled that this report[1] tells of an offer by the Minister of Health and Secretary of State for Scotland of an extra £2 million to augment the practitioners' central pool, subject to conditions. These conditions include "satisfactory methods of distribution," "significantly lower effective maximum numbers of patients," and the taking by the committee of "all possible steps to eliminate extravagance in prescribing." The G.M.S.C. found itself unable to recommend acceptance of the Government's offer, and it has called a special conference of local medical committees in July to discuss future action. If the conference acts as the committee recommends, it will call on the Minister of Health to refer to arbitration the determination of the proper size of the central pool, and it will suggest that once this has been determined by arbitration the G.M.S.C. should resume discussions to find and apply the best form of distribution. As we note on a later page, the Representative Body debated at some length this report from the General Medical Services Committee. In general, representatives reacted favourably to the committee's proposals, and the discussion ended with an expression of confidence in the conference of local medical committees, and a pledge of support to the conference in its efforts to secure a full and just settlement of the practitioners' claim.

It is difficult to see how the profession could accept an arbitrary offer of £2 million, made with no contention that this is the sum required for a just settlement. The Government's argument is that this is all the money remaining when other demands on the budget of the health services have been satisfied; it offers no agreement that the size of the pool should be related to present or to future numbers of doctors in general practice. Furthermore, acceptance by the profession of the condition that everything shall first be done to eliminate extravagance in prescribing could perhaps be misread as a bid by doctors to augment their own incomes at the cost of their patients' proper needs. The *Times*[2] remarks that the profession's representatives

> "are demanding, reasonably enough, that the 'right' size of the 'pool' should be determined by arbitration. It is high time that this question, among others, should be publicly investigated by some body capable of taking an impartial view. It should not be supposed, however, that the size and the nature of the rewards appropriate to one group of doctors will ever be satisfactorily settled until some more far-ranging inquiry does what the Spens inquiries failed to do—that is, achieves a balanced view of the rewards appropriate to all the leading professions in the health service."

This is an apt comment. General practitioners' remuneration was the subject of the first of the Spens reports. The figures for doctors' incomes available to the Spens Committee were themselves already nearly ten years old; and there were no comparable figures (such as were later produced) for the earnings of consultants or specialists—or of dentists. This committee had to content itself with pointing to the need for keeping the rewards of general practice related to those of the specialist:

> "We consider that it would be disastrous to the profession and to the public if general practice were recruited only from the less able young doctors."
>
> "It is important to improve prospects in general practice in order to render this branch of medicine sufficiently attractive to prevent all the abler men endeavouring to enter specialist service."

Furthermore, a later Spens inquiry assessed the appropriate level of the general practitioner's income as one eighth more than that of a general dental practitioner.

These good intentions have not, however, been translated into facts. The volume of the general practitioner's work has risen, but his comparative income has shrunk; and now he clearly belongs to the least well off of all "the leading professions in the health service." Were this not so our present registrar problem would not have become so pressing nor so insoluble. If only the prospects for the good practitioner, undertaking satisfying and unhurried work, could stand comparison even with those for the least successful of the men reaching consultant status, the consultant field would have exerted a less magnetic attraction to the young graduate, and general practice would not need to derive its recruits—as is fast becoming the case—mainly from those who cannot gain a foothold in a specialty. The general practitioners have no quarrel with the main conception of the Spens report—that of a range of incomes attainable in different proportions by practitioners throughout the service. They would wish to retain this conception but to have it realistically translated into present day money values, with due regard to the need for more doctors in many areas, to the rising expenses of practices, and to the incomes attainable by comparable professional colleagues within the health service. It must not be forgotten that the moneys hitherto paid into the central pool have not been assessed on any agreed calculation of the proper total to satisfy the Spens recommendations, but were provided by the Minister of Health to get the scheme started.

Practitioners may reasonably decline formally to relate economy in prescribing to adjustment of their remuneration, though the far sighted are increasingly alive to the need for sensible care. There can,

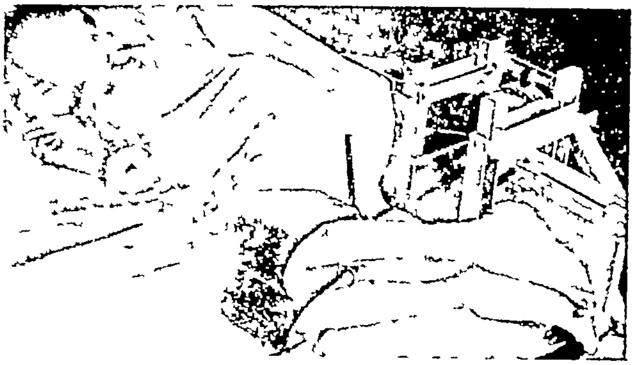

Fig 2—Position of legs before traction

skin and other tissues through which the force is applied We have found that traction of up to 150 lb applied at right-angles to a skin surface for half an hour does not damage the skin

The main features of the apparatus are apparent from fig 1 The source of power is a hydraulic jack (J) operated and released by the lever (L) Traction is exerted through a bicycle chain attached at one end to a spring balance recording up to 200 lb The bicycle chain passes over a sprocket on the jack (S) in such a way as to cause the chain to travel twice as far as the head of the jack This gives a wide range of action The counter-thrust surfaces (C) for buttocks and heels fold downwards when not in use The heels rest on a rubber pad mounted on a frame which slides distally as the legs become straightened A conveniently placed handle (H) is so fitted as to provide for the jack being returned to its lowest position before use

Figs 2 and 3 illustrate the use of the apparatus in a patient with chronic myelitis who had in recent months developed flexion contractures and pressure sores With traction of about 150 lb applied to both lower limbs together, the contracture yielded in the course of a few minutes, and correction was maintained in this way for half an hour twice daily The pull is elastic (through the spring balance) and the force applied drops as the contracture gives After treatment it is best for the patient to lie prone for an hour, as this posture tends to inhibit flexion spasms, but the best way of counteracting flexion spasms is weight-bearing, and with suitable splints this became possible in the case illustrated

Used in this way the apparatus is very stable, and it is seldom necessary to use the fixing legs for the wheels Another application of the apparatus is seen in fig 4, where adductor spasm is being countered by traction of 100 lb maintained for half an hour at a time The counter thrust in this case is taken up by the special arms fitted for the purpose

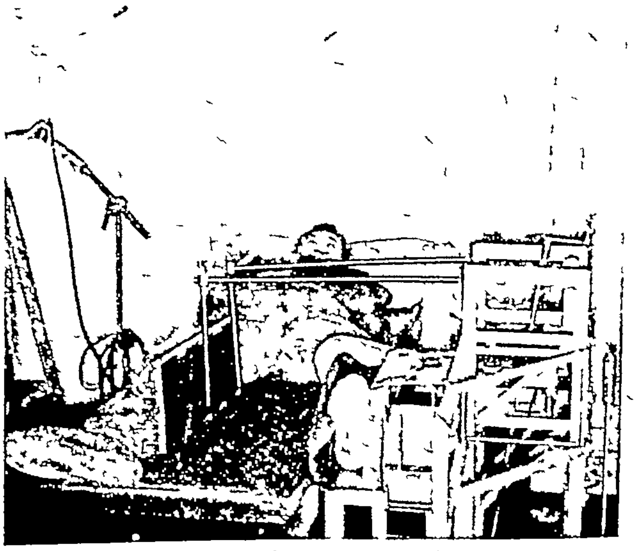

Fig 4—Apparatus applied for treatment of adductor spasm

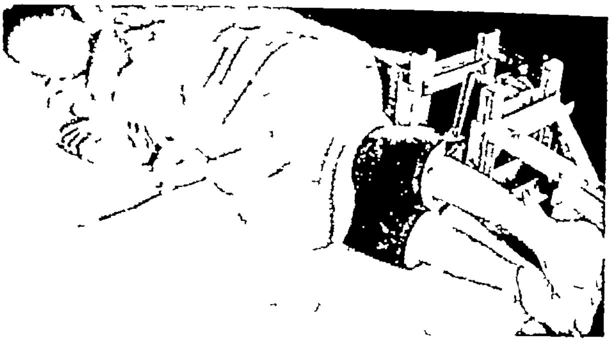

Fig 3—Position of legs after traction

The apparatus has been used with benefit in all of five cases treated, and it seems to have other possible applications which have not yet been explored

The instrument shown in figs 1 and 4 is an improved model constructed by Messrs H G East & Co, Longworth Road, Oxford

Reviews of Books

Textbook for Health Visitors

LLYWELYN ROBERTS, M D, M R.C.P, medical officer of health, Sheffield, I G DAVIES, M D, M.R.C.P, medical officer of health, Leeds, BERYL CORNER, M D, M.R.C.P, physician, Bristol Hospital for Sick Children. London Baillière, Tindall, & Cox 1951 Pp 552 21s

THIS book is intended primarily for the health visitor in training and after qualification It covers the revised syllabus for the examination for the health visitors' certificate of the Royal Sanitary Institute, and, as would be expected from the experience and status of the authors, does so very competently, in clear and simple language. The expanded sphere of duties placed on the health visitor by the National Health Service Act is reflected in the contents, and this "family adviser and friend" is given some guidance in geriatrics and sociology "The essentials of social care work are that it should be directed, purposeful, and specific This will distinguish it from meddlesome prying into the private lives of individuals. Like meddlesome midwifery, meddlesome social work may do great harm" This is indeed wise guidance, and we hope that the authors, in their next edition, will consider omitting the sections on anatomy and physiology to make space for further consideration of health education, the mental development of the child, the technique of interviewing, and the scope of social medicine

Hirndurchblutungsstörungen

Klinik und arteriographische Diagnose A BROBEIL, Dozent an der Universitäts Nervenklinik, Marburg Lahn Stuttgart Thieme 1950 Pp 204 D M 45

THIS monograph on the disturbances of cerebral circulation is based on Dr Brobeil's series of 16 patients suffering from thromboangiitis obliterans (Buerger's disease) with involvement of the brain In his investigations he made full use of Moniz's arteriographic method, and he shows the diagnostic application of the arteriogram in many well-reproduced examples The emphasis on the cases of Buerger's disease throws the book somewhat out of balance, and the chapters on the anatomy, physiology, and pathology of cerebral circulation are hardly more than useful, though not very critical, abstracts from textbooks Sometimes the information given is incomplete there is for instance no mention of the cerebral drainage system Cerebral vascular crises, including migraine and epilepsy, are mainly discussed from the clinical point of view, and the value of the last chapter, on arteriosclerosis of the brain, is enhanced by characteristic arteriograms at various stages of the disease The list of references contains the important publications of central European workers

however, be less ground for refusing to consider reduction in the maximum size of lists Such a revision is clearly necessary both to ease the lot of the practitioners with the smaller lists, and to ensure that doctors shall be found where they are most needed Spreading the hardship caused by an undersized central pool need not undermine the case for its adjustment, and readiness to take such a step would reflect both professional loyalty and professional responsibility

Prevention of Diabetic Complications

FROM the beginning of the insulin era writers on the control of diabetes have disagreed on how complete a restoration to physiological normality should be the aim Some, such as TOLSTOI[1] and LICHTENSTEIN,[2] advocate a " free diet " with enough insulin to prevent diabetic symptoms and acidosis, without regard to hyperglycæmia and glycosuria, whereas idealists like JOSLIN[3] and JACKSON[4] believe in using insulin and a strict diet to restore the patient's metabolism as closely as possible to normality The " free diet " protagonists base their treatment on the assumption that the vascular, renal, and ocular complications of diabetes are part and parcel of the disease and are thus not materially affected by insulin and strict control A good deal of published work supports this view Thus DOLGER[5] found that every one of 200 diabetics of 25 years' standing had retinal hæmorrhages, regardless of age of onset, severity of the diabetes, or type of treatment applied In 1938, WARREN[6] claimed that he had never seen a necropsy on a diabetic, whose disease had lasted 5 years or more, free from arteriosclerosis, regardless of age, but by 1946 he had found 4 exceptions As lately as last year GOADBY and JACOBS[7] concluded that in their clinic routine treatment had no effect on the incidence of vascular and eye complications, although good control did reduce the incidence of neuropathy

The burden of proving any effect of good control on these complications has rested with those maintaining exact insulin dietary balance over many years in diabetics who after 20 years' treatment are still not old enough to be at the stage of senile degeneration Some of the earlier studies[8] included patients in whom diabetes started before insulin was available, and, however well controlled their condition may have been eventually, these patients must at first have passed through a phase of poor control Even in the most strictly supervised cases personal and environmental factors rule out the possibility of constantly maintaining the blood sugar within the normal range Cases can, however, be classified according to the constancy of control, and in 1949 JACKSON and his group[4] in Iowa described what they believed was the first objective evidence that the level of control is important in determining degenerative changes In their study of 75 unselected diabetics of 10 years' standing, one worker made a numerical rating of the degree of control, while another, who was oblivious of the control ratings, examined the patients for degenerative changes 30% had good control ratings, and these patients had no significant complications Only the patients with poor control had the more advanced degenerative changes JACKSON concluded that the level of control and the duration of the diabetes were important factors governing complications This year a comprehensive study of 247 diabetics of 10-34 years' standing, seen at JOSLIN's clinic,[9] has added weight to JACKSON's results All 247 patients in this study developed diabetes between the ages of 18 months and 30 years, and for the purpose of the survey degenerative changes were sought by numerous clinical, laboratory, and radiological investigations, including radiographs for arterial calcification and heart size, electrocardiographs, capillary-fragility tests, detailed examinations of the eyes, renal function tests, and determination of the blood-fat and blood-protein levels Levels of control were assessed strictly, and to gain the label " excellent control " the patient had to satisfy each of the following criteria (1) never been in coma, (2) insulin begun within a few weeks of the onset of diabetes, (3) urinary sugar tests done more than once daily since the onset, with a conscientious attempt to keep the urine sugar free before meals by varying the insulin dosage according to the tests, (4) diet weighed for at least 80% of the time since the first appearance of diabetic symptoms, and (5) physical examination and laboratory tests by a doctor at least once a year, with satisfactory blood and urine tests One might expect that few would deserve this rating, and in fact only 7 of the 247 did so 30 were classified as having " good control " on slightly less strict criteria, and the excellent and good groups comprised 15% of the series 21% had fair control, and 64% poor It was found that this classification did not cause any bias between the groups with regard to age of onset or to insulin dosage, but 63% of the patients with good or excellent control had had diabetes for more than 20 years, whereas only 38% of the patients with poor or fair control had had diabetes for such a time This may indicate that careful control prolongs life, but there is even better reason to believe that careful control prevents severe degenerative complications Thus no patients with excellent or good control showed advanced vascular calcification, or retinopathy, or any evidence of diabetic nephropathy, even after 20-34 years of diabetes In the group of 103 patients with diabetes for periods of 20-34 years, 3 of the 4 cases with excellent control had no retinal lesions, and of 54 with moderate to marked retinopathy all but 5 had fair or poor control, and none excellent DYER's group[10] in Philadelphia confirm from their series of 50 patients with diabetes for 10 or more years that retinal lesions are significantly correlated with poor control of the diabetes

It thus seems that, in preventing degenerative complications, strict regulation of the diabetes is more important than the duration or severity of the disease Juvenile diabetics, who as a class seem to be intellectually above average,[4, 9] may by strict control be saved from tragic complications at what should be the prime of their lives

Cures of Peptic Ulcer

At Slough the waiting-room of a chemist who cures peptic ulcers is brimful of grateful patients and hopeful newcomers, and those who have encountered some of his cures will know that the gratitude is profound and the cure—apparently—complete These recovered patients eat anything, they work as hard as they please, and they are confident that this man has found the only answer to a problem still baffling the doctors Mr John Parr, who is doubtless more sophisticated than the average run of the patients seeking help at Slough, tells us in a new book [1] how, after some 25 years of severe suffering he was cured of a duodenal ulcer by means of a low-fat diet, and he has since remained well for 5 years All physicians who treat large numbers of patients with peptic ulcer have many records of patients who responded to treatment, and who remained well for 5 years or longer, even in some cases for good, and they also have records of failures As Mr Parr explains at length and beautifully clearly, we do not yet understand the mechanisms producing peptic ulcers, or the conditions necessary for their cure

How much do we, in fact, know ? We know that ulcers are becoming commoner, especially in men, though at one time they were commoner in women We know that gastric and duodenal ulcers behave differently (a point which Mr Parr does not make), and that acute ulcers behave differently from chronic ulcers We know, from the experiments of Wolf and Wolff [2] on "Tom" (whose gastric mucosa was so conveniently visible), that the stomach shares with the face the vascular effects of emotion, going pale with fear and depression, red with wrath, and that the mucosa of a stomach so engorged will bleed even if stroked gently with a glass rod We are just beginning to study vascular shunt mechanisms of the stomach which may at times render the ulcer bearing area ischæmic We have evidence that acute ulcers produced experimentally in animals always heal within three weeks if the causal drug or irritant is withdrawn We have records of "ulcer families" though we cannot say whether it is a predisposition to ulcer or an ulcer temperament which is inherited, or whether the new generation is merely bred in an ulcer-provoking environment We are well aware, of course, that ulcer relapses are very often associated with anxiety, and two types of "ulcer temperament" have been described—an ambitious, tense, self driving type, anxious for success, and a quiet over conscientious worrying type, anxious to be fed and cherished and hiding his emotions under a calm exterior We have a deal of information about the secretion of acid by the stomach, and its behaviour in the ulcer-patient, and we have some evidence that hypersecretion—especially nocturnal—is often associated with duodenal, though not with gastric, ulcers We also know that chronic ulcers rarely develop during pregnancy, and that symptoms if present usually subside at this time We know that acute ulceration sometimes follows skin burns (Curling's ulcer) and that a chronic ulcer often develops at the constricting ring of a diaphragmatic hernia We know all too well that the characteristic life history of an ulcer is one of remissions—perhaps for 10 or 15 years—and exacerbations It is easy to see that the complex story is still only half unfolded, and that Mr Parr is right when he says we do not really know what causes an ulcer

In treatment the position is much the same We know that ulcers come and go without fixed rules, and that almost any diet will let an ulcer heal at some times and not at others Very strict and boring diets often fail, while a little freedom—occasionally a lot of freedom—may succeed If a patient has been dieted until he is afraid of all food except milk and eggs, and dismally tired of those, it may well be that strong suggestion will break the vicious circle "Do this (or take that) for so many days, and then go ahead and eat what you like!" may work a cure—or at any rate produce remission—where orthodox caution perpetuates the pain Again, the enthusiasm of the doctor or surgeon over a new method of treatment may carry the patient to victory, as has so often happened in the history of this disease Mr Parr tilts at such fashions in treatment—at gastro enterostomy, partial gastrectomy, vagotomy, histidine, alkalis, sedatives, and especially the Lenhartz and Sippy diets—though all of these have cures to their credit With pardonable obtuseness and loyalty he has nothing but praise for the low fat diet to which he happened to respond, or for Dr J J Spira who introduced him to it, and whose views on ulcer causation he gives at some length As is well known, Dr Spira attributes the development of ulcers to the interaction of the gastric acid with bile Mr Parr quotes him as saying that bile causes an inflammation of the mucosa, and thus allows the acid to erode the surface and cause an ulcer, and that fat "attracts the bile" into the stomach—hence, cut down fat It is a simple theory, not originated by Dr Spira (though Mr Parr credits him with it) As long ago as 1863 it was suggested that bile salts are toxic to the upper digestive tract, and in 1914, Smith [3] showed that bile acids may produce ulceration in cats by direct contact with the mucous membrane Normally the layer of mucin covering the membrane probably prevents such direct contact, and the importance of this substance may well be greater than we yet realise Nevertheless the very extensive experimental studies on the relationship of bile to peptic ulceration, though often contradictory, have not suggested that bile itself plays any causative part in ulcer formation. Indeed most of the laboratory findings have been directly to the contrary in so far, for example, as removal of the bile from the stomach and duodenum in animals, either by ligation of the bile duct or by biliary drainage externally or internally, is followed by ulcer formation in between 25% and 55% of cases, furthermore such ulcers are prevented, and the animals kept in good health, if ox bile salts are fed to them by mouth No final conclusions, however, are yet possible from the many animal experiments, and unfortunately this is equally true of clinical investigations Since Dr Spira's book was published in 1931, low fat diets for ulcer patients do not appear to have received much support from doctors, or to have proved the universal cure for the condition which Mr Parr would like to believe The diet he was ordered was in fact so varied and generous that without necessarily subscribing to Dr Spira's theory many ulcer patients, and other dyspeptics, must with little doubt have often adopted it Certainly the view that hot fats are harmful to ulcer patients has little novelty, it has indeed lately received convincing support from the work of Kay,[4] who has shown that, while uncooked fat has a depressant action on gastric activity, cooked fats stimulate both acid secretion and motility, the longer the heating the more stimulant is their effect

Whatever may have been the mechanisms in Mr Parr's successful "cure," none will question that he has been freed of symptoms for 5 years; perhaps a further volume after another 5 years may carry his inquiries and experiences further still By setting out—on the whole fairly—the story of the search for the causes and cure of ulcer in a lucid and popular manner he will give some insight into their symptoms to many laymen suffering from this disability It may be questioned whether he has done a service to Dr Spira, who may well find the publicity unwelcome, and who would doubtless be among the first to agree that methods of treatment other than his have been and continue to be successful Such a book as Mr Parr's could have been written by many another ulcer patient, except that the vaunted remedy would be different We have not found the answer yet, nor should the public be encouraged to think we have reached the end of the search

Annotations

FLUORINE AND DENTAL CARIES

In the U S A and Canada protracted investigations of the effect of artificial fluorination of drinking water on dental caries have so far yielded satisfactory results[5], and the enterprise of Anglesea County Council in seeking authority to add fluorine to the water supply[6] may mark the beginning of a great advance in the control of dental caries in this country A pilot survey[7] in England suggests that the optimum fluorine content for drinking water is 1 0–1 2 p p m Greater concentrations than this cause mottling of the enamel, which becomes severe at 5 p p m, at still higher concentrations toxic symptoms and bone lesions may arise Brun and his colleagues[8] believe, however, that osteosclerosis will develop only with a daily fluorine intake of at least 28 mg over many years To protect teeth fluorine must be given during the first 8 years of life, after this age and after eruption it has little or no effect[9] Opinions differ on the duration of protection Weaver[10] assesses it as the equivalent of a delay of five years in the onset of caries, while some workers in the U S A believe that the protection is permanent

In the English pilot survey three high fluorine areas (North Shields, Colchester, and Slough) were compared with three low fluorine areas (South Shields, Ipswich, and Reading), the inquiry was confined to mothers attending antenatal clinics and infant welfare centres, and to children attending day nurseries, infant welfare centres, and nursery schools In the high fluorine areas the water fluorine content ranged from 0 8 to 1 45 p p m, and in the other areas from 0 07 to 0 3 p p m No severely mottled teeth were found in the high fluorine areas, and such mottling as there was could be detected only by careful clinical examination In the high fluorine areas the incidence of caries was lower in every age group —by as much as 38% in those aged 21–25 years—with an apparent delay of 10 years in the onset of caries It was also observed that fewer teeth were missing and that caries was less severe With the children, whose ages ranged from 2 to 5 years, the reduction in the incidence of caries was already apparent at 2–3 years of age, and was as great as 59% at 2 years

It seems that the fluorination of water supplies should play a great part in the fight against dental caries Clearly, however, no one measure will ever conquer this disease

DRUG ADDICTION IN AMERICA

Drug peddling, an ugly crime by any measure, becomes peculiarly detestable when buyers are sought among children The investigation into the drug traffic which is being conducted in New York[1] by Mr Nathaniel Goldstein, the attorney general, has revealed the widespread use of drugs—marihuana, cocaine, heroin, and amphetamine—by boys and girls in the high schools of the city Some of these children acquire the habit at ages as early as 12 or 13, usually beginning by smoking marihuana cigarettes—"reefers"—which are sold to them by older children in the school Nor is it clear that these older children are necessarily the tools of adult vendors some, at least, seem to have set up in business for themselves Among the addicts whose recorded confessions were played back in the course of the inquiry, a woman of 25 told of a candy store where high school children of 14 and 15 sold drugs after school hours, and the same children could be approached during morning break, when they would peddle drugs over the playground fence A 17 year old boy, who was running a successful business as a bookie in his school, spoke of a school fellow who dealt in drugs among the children and made as much as $300–400 a day Asked how much he himself made as a bookie the informant replied "That's my business" The inquiry revealed clearly the stages in which addiction is acquired a reefer, or a "snort" of cocaine is given free at first, then a moderate charge is made, once the child becomes an addict prices rise, and to get the necessary cash the young people spend money saved to pay for education or hospital treatment, steal, housebreak, or take to prostitution It has been estimated that 1 in every 200 children in the city uses narcotic drugs, and one witness spoke of young parents who quiet their baby with a shot of heroin In 1946, of 712 people arrested for offences against the narcotic drugs laws, 3 were aged 16, and 30 were between 17 and 21 By 1950 the numbers of those arrested had risen to 2482, of whom 63 were 16 year olds and 458 between 17 and 20 The numbers of those in their 'teens who were arrested had increased sixteenfold during this period

The plight of the young addict who wishes to be cured is very unfortunate if he admits his trouble he is liable to be jailed for the offence of buying drugs A girl of 19, who asked the help of the biology teacher in her school, was nevertheless obliged to go through the courts, she was of the opinion that many young people would confess to their addiction if they could hope to be treated as patients, not as criminals There are disquieting indications that some members of the New York police force countenance drug traffic in order to collect bribes Certainly the police can hardly have failed to know how very widespread drug peddling is one addict mentioned by name over forty bars, cafeterias luncheon places, and drug and candy stores where she had bought narcotics or seen them bought One at least was opposite a police station She described the technique of the salesmen, some of whom must be approached with a request, while some come over to ask if anything is wanted or follow the customer out into the street On the broadwalk of Coney Island it seems that peddlers openly accost passers-by with offers of drugs

A statement by the Senate Crime Investigating Committee in Washington suggests that there, too, and in Baltimore, the trade in illicit drugs is busy, though probably not as widespread among young people as in New York The results of these inquiries have been so gravely disturbing that a national investigation is likely to be undertaken Meanwhile the police of thirty six countries, who met in Lisbon at the beginning of June, have agreed to intensify the safeguards against smuggling of narcotics by air

THE LISTER INSTITUTE

THE latest report of the Lister Institute describes the great variety of work carried out there in the past year The effect of inactivating vaccinia virus with ultraviolet light has been studied with a view to determining whether the treated virus is antigenic A preliminary dose of an antigenic preparation of killed virus might reduce the incidence of complications in those vaccinated for the first time at school age or in later life The fate of the plasma substitute dextran has been investigated It appears that, in the rabbit, in the first few weeks after intravenous injection the dextran which is not excreted is distributed throughout all the tissues, including the brain, spinal cord, and cerebrospinal fluid, the heaviest deposits are found in the liver In heavily loaded animals dextran has been detected serologically in saline extracts of the following tissues at six months after injection, in the brain, spinal cord, bone marrow, lungs, liver, kidney, skeletal and cardiac muscle, stomach, and lymph glands, at nine months after injection, in the cerebrospinal fluid, bone marrow, skeletal muscle, kidney, liver, and lymph glands, and at twelve months after injection, in the brain, cerebrospinal fluid, liver, kidney, and lymph glands

In the biochemical division the gene product responsible for the "Lewis" Le^a blood group character has been isolated and characterised The material is a mucoid very similar to the human group A substance described earlier The main components—fucose, galactose, glucosamine, chondrosamine, and eleven amino acids—appear to be common to both substances, and further studies are being made to determine the amounts of each of the components present in the group substances Preliminary experiments have been carried out on the oxidation of the Le^a substance with the periodate ion in order to compare the behaviour of this substance with that of the group A substance under similar conditions The blood group research unit has been concerned with finding "new" blood group systems, and filling gaps of knowledge in "old" ones The first problem is being approached by testing serum of persons known to have been immunised by pregnancy or transfusion, it is in such sera that antibodies defining "new" antigens have in the past usually been found. As a more active measure the unit is giving small injections of blood to more than a hundred volunteers in the hope that some of them may respond by making antibodies to antigens yet unknown or only guessed at In the filling of gaps in the knowledge of blood groups, the unit was fortunate in being sent a sample of blood which served to answer the problem of whether the three pairs of the Rh complex are separable or not The blood sample came from a person who was found to lack two of the three parts, which parts [illegible] are evidently separable Further, the missing antigens presumably reflect a small deletion in the Rh chromosome Deletion is a phenomenon familiar in species which have been well studied genetically, but no good case has previously made out for its occurrence in man

The Blood group Reference Laboratory has continued to supply blood grouping serum of all kinds to the National Blood Transfusion Service, and to other users at home and abroad Increased work has made it necessary to increase the technical and maintenance staff

THE TOXICITY OF BERYLLIUM

THE story of beryllium and the part it plays in industrial toxicology is fascinating and contradictory Few people are completely sure that beryllium is the sole cause of the illnesses ascribed to it Yet American investigators, led by the late Dr Leroy U Gardner, have built up a strong case against it, despite the findings of Fairhall and others[1] in 1943 that no specific toxic action is attributable to the beryllium ion The illnesses found amongst beryllium workers fall into two broad groups an acute pneumonitis occurring amongst workers engaged in extracting the metal and its salts from the ore, and a delayed or chronic condition variously termed "delayed chemical pneumonitis" or "pulmonary granulomatosis," usually found among fluorescent lamp makers The latter condition has many of the features of acute or subacute silicosis, but may resemble other conditions such as Boeck's sarcoidosis and miliary tuberculosis In the early stages of the investigation Gardner, with the weight of his great authority, demolished the silicosis theory, which does not seem to have been seriously considered since then, but this may well be one instance in which Gardner was wrong Both the acute and the delayed illnesses could be explained without reference to beryllium The acid radicals in beryllium fluoride and sulphate, to which the workers in the extraction processes are mainly exposed, could account for the acute pneumonitis, which somewhat resembles œdema of the lungs The powders used for coating fluorescent lamps contain much more silica than beryllium, and it seems illogical to ascribe an illness caused by the inhalation of a composite or compound dust to the smallest ingredient But as T L Shipman said in the Sixth Saranac Symposium[2]

> 'it is significant that delayed chemical pneumonitis, if it is not Boeck's sarcoid is closely similar, that it has certain characteristics in common with silicosis and that it can even resemble tuberculosis enough to make one stop and think Because of the complexity of the problem, let me speak a warning against hasty conclusions Our task demands the humility which ensures an open mind '

Throughout this conference there was a doubt, expressed and implied, whether beryllium was really the prime cause of both types of illness But one speaker was prepared "to stick out his neck," as he put it, and pronounce categorically that the cases of poisoning with which he had to deal were in fact instances of beryllium poisoning No one, however, was equally prepared to state that they were not As regards terminology, the conference came to the conclusion that it would be unwise in the present state of uncertainty to use the term "beryllium poisoning", but that it would be better to call the acute disease "acute pneumonitis of beryllium workers" and the chronic or delayed disease "pulmonary granulomatosis of beryllium workers" was ordered was in fact so varied and generous that without necessarily subscribing to Dr SPIRA's theory many ulcer patients, and other dyspeptics, must with little doubt have often adopted it Certainly the view that hot fats are harmful to ulcer patients has little novelty, it has indeed lately received convincing support from the work of KAY,[4] who has shown that, while uncooked fat has a depressant action on gastric activity, cooked fats stimulate both acid secretion and motility, the longer the heating the more stimulant is their effect

Whatever may have been the mechanisms in Mr PARR's successful "cure," none will question that he has been freed of symptoms for 5 years; perhaps a further volume after another 5 years may carry his inquiries and experiences further still By setting out—on the whole fairly—the story of the search for the causes and cure of ulcer in a lucid and popular manner he will give some insight into their symptoms to many laymen suffering from this disability It may be questioned whether he has done a service to Dr SPIRA, who may well find the publicity unwelcome, and who would doubtless be among the first to agree that methods of treatment other than his have been and continue to be successful Such a book as Mr PARR's could have been written by many another ulcer patient, except that the vaunted remedy would be different We have not found the answer yet, nor should the public be encouraged to think we have reached the end of the search

FLUORINE AND DENTAL CARIES

IN the U S.A and Canada protracted investigations of the effect of artificial fluorination of drinking water on dental caries have so far yielded satisfactory results [5], and the enterprise of Anglesea County Council in seeking authority to add fluorine to the water supply [6] may mark the beginning of a great advance in the control of dental caries in this country A pilot survey [7] in England suggests that the optimum fluorine content for drinking water is 1 0–1 2 p p m Greater concentrations than this cause mottling of the enamel, which becomes severe at 5 p p m, at still higher concentrations toxic symptoms and bone lesions may arise Brun and his colleagues [8] believe, however, that osteosclerosis will develop only with a daily fluorine intake of at least 28 mg over many years To protect teeth fluorine must be given during the first 8 years of life, after this age and after eruption it has little or no effect [9] Opinions differ on the duration of protection Weaver [10] assesses it as the equivalent of a delay of five years in the onset of caries, while some workers in the U S A believe that the protection is permanent

In the English pilot survey three high fluorine areas (North Shields, Colchester, and Slough) were compared with three low fluorine areas (South Shields, Ipswich, and Reading), the inquiry was confined to mothers attending antenatal clinics and infant welfare centres, and to children attending day nurseries, infant welfare centres, and nursery schools In the high fluorine areas the water fluorine content ranged from 0 8 to 1 45 p p m, and in the other areas from 0 07 to 0 3 p p m No severely mottled teeth were found in the high fluorine areas, and such mottling as there was could be detected only by careful clinical examination In the high fluorine areas the incidence of caries was lower in every age group —by as much as 38% in those aged 21–25 years—with an apparent delay of 10 years in the onset of caries It was also observed that fewer teeth were missing and that caries was less severe With the children, whose ages ranged from 2 to 5 years, the reduction in the incidence of caries was already apparent at 2–3 years of age, and was as great as 59% at 2 years

It seems that the fluorination of water supplies should play a great part in the fight against dental caries Clearly, however, no one measure will ever conquer this disease

DRUG ADDICTION IN AMERICA

DRUG PEDDLING, an ugly crime by any measure, becomes peculiarly detestable when buyers are sought among children The investigation into the drug traffic, which is being conducted in New York [1] by Mr Nathaniel Goldstein, the attorney general, has revealed the widespread use of drugs—marihuana, cocaine, heroin, and amphetamine—by boys and girls in the high schools of the city Some of these children acquire the habit at ages as early as 12 or 13, usually beginning by smoking marihuana cigarettes—"reefers"—which are sold to them by older children in the school Nor is it clear that these older children are necessarily the tools of adult vendors some, at least, seem to have set up in business for themselves Among the addicts whose recorded confessions were played back in the course of the inquiry, a woman of 25 told of a candy store where high school children of 14 and 15 sold drugs after school hours, and the same children could be approached during morning break, when they would peddle drugs over the playground fence A 17 year old boy, who was running a successful business as a bookie in his school, spoke of a school fellow who dealt in drugs among the children and made as much as $300–400 a day Asked how much he himself made as a bookie the informant replied "That's my business" The inquiry revealed clearly the stages in which addiction is acquired a reefer, or a "snort" of cocaine is given free at first, then a moderate charge is made, once the child becomes an addict prices rise, and to get the necessary cash the young people spend money saved to pay for education or hospital treatment, steal, housebreak, or take to prostitution It has been estimated that 1 in every 200 children in the city uses narcotic drugs, and one witness spoke of young parents who quiet their baby with a shot of heroin In 1946, of 712 people arrested for offences against the narcotic drugs laws, 3 were aged 16, and 30 were between 17 and 21 By 1950 the numbers of those arrested had risen to 2482, of whom 63 were 16 year-olds and 458 between 17 and 20 The numbers of those in their 'teens who were arrested had increased sixteenfold during this period

The plight of the young addict who wishes to be cured is very unfortunate if he admits his trouble he is liable to be jailed for the offence of buying drugs A girl of 19, who asked the help of the biology teacher in her school, was nevertheless obliged to go through the courts, she was of the opinion that many young people would confess to their addiction if they could hope to be treated as patients, not as criminals There are disquieting indications that some members of the New York police force countenance drug traffic in order to collect bribes Certainly the police can hardly have failed to know how very widespread drug peddling is one addict mentioned by name over forty bars, cafeterias, luncheon places, and drug and candy stores where she had bought narcotics or seen them bought One at least was opposite a police station She described the technique of the salesmen, some of whom must be approached with a request, while some come over to ask if anything is wanted or follow the customer out into the street On the broadwalk of Coney Island it seems that peddlers openly accost passers by with offers of drugs

A statement by the Senate Crime Investigating Committee in Washington suggests that there, too, and in Baltimore, the trade in illicit drugs is busy, though probably not as widespread among young people as in New York The results of these inquiries have been so gravely disturbing that a national investigation is likely to be undertaken Meanwhile the police of thirty six countries, who met in Lisbon at the beginning of June, have agreed to intensify the safeguards against smuggling of narcotics by air

THE LISTER INSTITUTE

THE latest report of the Lister Institute describes the great variety of work carried out there in the past year The effect of inactivating vaccinia virus with ultraviolet light has been studied with a view to determining whether the treated virus is antigenic A preliminary dose of an antigenic preparation of killed virus might reduce the incidence of complications in those vaccinated for the first time at school age or in later life The fate of the plasma substitute dextran has been investigated It appears that, in the rabbit, in the first few weeks after intravenous injection the dextran which is not excreted is distributed throughout all the tissues, including the brain, spinal cord, and cerebrospinal fluid, the heaviest deposits are found in the liver In heavily loaded animals dextran has been detected serologically in saline extracts of the following tissues at six months after injection, in the brain, spinal cord, bone marrow, lungs, liver, kidney, skeletal and cardiac muscle, stomach, and lymph glands, at nine months after injection, in the cerebrospinal fluid, bone marrow, skeletal muscle, kidney, liver, and lymph glands, and at twelve months after injection, in the brain, cerebrospinal fluid, liver, kidney, and lymph glands

In the biochemical division the gene product responsible for the "Lewis" Le^a blood group character has been isolated and characterised The material is a mucoid very similar to the human group A substance described earlier The main components—fucose, galactose, glucosamine, chondrosamine, and eleven amino acids—appear to be common to both substances, and further studies are being made to determine the amounts of each of the components present in the group substances Preliminary experiments have been carried out on the oxidation of the Le^a substance with the periodate ion in order to compare the behaviour of this substance with that of the group A substance under similar conditions The blood group research unit has been concerned with finding "new" blood group systems, and filling gaps of knowledge in "old" ones The first problem is being approached by testing serum of persons known to have been immunised by pregnancy or transfusion, it is in such sera that antibodies defining "new" antigens have in the past usually been found As a more active measure the unit is giving small injections of blood to more than a hundred volunteers in the hope that some of them may respond by making antibodies to antigens yet unknown or only guessed at In the filling of gaps in the knowledge of blood groups, the unit was fortunate in being sent a sample of blood which served to answer the problem of whether the three pairs of the Rh complex are separable or not The blood sample came from a person who was found to lack two of the three parts, which parts are therefore evidently separable Further, the missing antigens presumably reflect a small deletion in the Rh chromosome Deletion is a phenomenon familiar in species which have been well studied genetically, but no good case has previously made out for its occurrence in man

The Blood group Reference Laboratory has continued to supply blood grouping serum of all kinds to the National Blood Transfusion Service, and to other users at home and abroad Increased work has made it necessary to increase the technical and maintenance staff

THE TOXICITY OF BERYLLIUM

THE story of beryllium and the part it plays in industrial toxicology is fascinating and contradictory Few people are completely sure that beryllium is the sole cause of the illnesses ascribed to it Yet American investigators, led by the late Dr Leroy U Gardner, have built up a strong case against it, despite the findings of Fairhall and others[1] in 1943 that no specific toxic action is attributable to the beryllium ion The illnesses found amongst beryllium workers fall into two broad groups an acute pneumonitis occurring amongst workers engaged in extracting the metal and its salts from the ore, and a delayed or chronic condition variously termed "delayed chemical pneumonitis" or "pulmonary granulomatosis," usually found among fluorescent lamp makers The latter condition has many of the features of acute or subacute silicosis, but may resemble other conditions such as Boeck's sarcoidosis and miliary tuberculosis In the early stages of the investigation Gardner, with the weight of his great authority, demolished the silicosis theory, which does not seem to have been seriously considered since then, but this may well be one instance in which Gardner was wrong Both the *acute* and the *delayed* illnesses could be explained without reference to beryllium The acid radicals in beryllium fluoride and sulphate, to which the workers in the extraction processes are mainly exposed, could account for the acute pneumonitis, which somewhat resembles œdema of the lungs The powders used for coating fluorescent lamps contain much more silica than beryllium, and it seems illogical to ascribe an illness caused by the inhalation of a composite or compound dust to the smallest ingredient But as T L Shipman said in the Sixth Saranac Symposium[2]

> 'it is significant that delayed chemical pneumonitis, if it is not Boeck s sarcoid is closely similar, that it has certain characteristics in common with silicosis and that it can even resemble tuberculosis enough to make one stop and think. *Because of the complexity of the problem, let me* speak a warning against hasty conclusions Our task demands the humility which ensures an open mind '

Throughout this conference there was a doubt, expressed and implied, whether beryllium was really the prime cause of both types of illness But one speaker was prepared "to stick out his neck," as he put it, and pronounce categorically that the cases of poisoning with which he had to deal were in fact instances of beryllium poisoning No one, however, was equally prepared to state that they were not As regards terminology, the conference came to the conclusion that it would be unwise in the present state of uncertainty to use the term "beryllium poisoning", but that it would be better to call the acute disease "acute pneumonitis of beryllium workers" and the chronic or delayed disease "pulmonary granulomatosis of beryllium workers" had to have the information The patient's consent was obtained in writing, and it was not really possible to go further than that Dr Brown said that he was satisfied if the ethical committee kept the matter under review to see that there was no further undermining of the doctor-patient relationship The motion was carried

REMUNERATION OF GENERAL PRACTITIONERS

The meeting had a lively discussion on the remuneration of general practitioners Strong disapproval of the Government's attitude and of the delays in settling the matter was expressed, but delegates rejected a call for early resignations from the health service and agreed to support a proposal for arbitration

Dr S Wand, chairman of the General Medical Services Committee, presented the report[1] to be laid before a special conference of representatives of local medical committees on July 19 Dr Wand emphasised that the committee had offered the fullest cooperation with the Ministry to provide the best possible service to the public General practitioners had played their part loyally and had earned the right to a just settlement It had been pointed out to the Minister of Health and the Secretary of State for Scotland that it was clear from the Spens report that general practitioners had been underpaid for many years before the war The general practitioner had a responsibility second to none, and his lot was worse than that of any other worker in the service Did the Ministers' offer implement the promise of a full inquiry ? They offered an inquiry with two preconceptions—first on the amount, secondly on the distribution The offer was for a maximum of £2 million, with conditions That amount was roughly one ninth of the practice expenses for the year ended March, 1950, since when the price of everything had gone up Was this an offer at all ? (Cries of "No ") If the practice expenses proved to have risen by over £2 million, practitioners would be worse off

If there was an epidemic everyone but the general practitioner would be getting paid for doing more work It was true that the Minister did suggest an improvement for the young man at the beginning—but he would have less to go for It appeared that the large list man would have no less work, but would have less money This might be a first step towards a levelling which would ultimately produce a full time salaried service "You may ask yourself if it has the effect of producing a split in the profession "

Prescribing costs were tied up with the offer The Drug Tariff showed how prices had increased compared with 1950 Old drugs were being replaced by ones with more specific action, and it was the practitioner's duty to prescribe them It seemed that the Ministers' proposal could only mean that a doctor, when prescribing, would have to consider whether an item in a particular prescription would affect his income, the public would feel anxious It seemed that the Government, having plunged headlong, against the profession's advice, into a comprehensive health service, held that the general practitioner should be the one to carry the burden In asking for arbitration on remuneration they were really asking for arbitration on betterment Excluding any reference to additional work, there was no doubt that their claim was several times above the maximum offered

"We have had inquiry after inquiry, delay after delay, we have been told about wage freezes and ceilings and rearmament All the time the general practitioner has been doing his work loyally The public knows we have had a raw deal " Yet the General Medical Services Committee was still being fair and reasonable, and it was recommending to the conference that the claim should be arbitrated on a computation of the changed value of money since 1939

Dr J I Milne moved a resolution by Manchester that, failing a satisfactory reply from the Minister by June 30, practitioners should submit their resignations forthwith They had been put off with one excuse after another, he remarked, and it was slowly dawning on them that they were being led by the nose When the British Medical Guild was formed last year general practitioners felt that at last something was being done, now that feeling had given way to cynicism Dr F S Catto (Manchester) said that their resignations would have to come some time if they were to get justice

Dr A C E Breach (Bromley) moved as an amendment that the principle of arbitration should be accepted, provided that the court of arbitration was independent, that its terms of reference should include as a basis the Spens recommendations, that it must take into account the remuneration of allied professions, that the findings should be binding, and that the award should be retrospective to July 5, 1948 Dr A V Russell (council) said that Mr Bevan had refused arbitration because he knew the profession would win Dr C P Wallace (Guildford) recalled that his division had suggested arbitration a year ago The real trouble was that a grievance of three years' standing had gone unredressed

Dr D P Stevenson, deputy secretary of the association, explained that if it was decided to ask for arbitration, the G M S C would call together committee A of the Medical Whitley Council of the National Health Service The management side would no doubt turn down the claim for a revision of the central pool, and then the staff side would ask for arbitration If the management side agreed, the matter could go before the Industrial Court If not, recourse could be made to Order 1305 They would rather go to the Industrial Court

A suggestion by Dr L V Goodliffe (Croydon) that there should be an interim award pending an award by arbitration was greeted with cries of "No "

After further discussion the meeting rejected the call for early resignations and Dr Breach's amendment, and expressed confidence in the conference of local medical committees, pledging support for the efforts of the conference to effect a full and just settlement

A motion by Gateshead preferring a fixed capitation fee was referred to council Dr Wand said that one reason for the discrepancy of capitation fees might be found to be the inflation of lists, he also mentioned that they believed that the extent of "unsigning " was considerable A motion from Lancaster calling for a national capitation fee was also referred to council

Dr Wand later made a statement on what would happen if the request for arbitration on the remuneration of general practitioners was refused It was, said Dr Wand, almost inconceivable that the Minister should decline to accept this reasonable statement "Should it become clear that the Minister does decline either to examine the case on its merits or to refer it to arbitration, a new situation will arise If such a situation should arise the committee would have seriously to consider recommending that general practitioners have no alternative but to withdraw their services from the National Health Service "

The meeting agreed with West Denbigh and Flint that in striving to secure adequate remuneration for the practitioner, due emphasis must be laid on the "alarming increase " in practice expenses

COMMITTEE ON GENERAL PRACTICE

With a few dissentients the meeting agreed with the Chelsea and Fulham division in taking a grave view of the fact that the Minister omitted to ask the General Medical Services Committee, as the recognised negotiating body for all general practitioners, for its views on the constitution, terms of reference, and membership of the committee set up by the Central Health Services Council to study general practice It was stated that the G M S C had not yet decided whether to give evidence before this committee, and Dr **Wand** added that the G.M S C sought an assurance from the Minister that the new committee would not deal with terms and conditions of service ; Dr D L **Gullick** (East Herts) thought that if the committee suggested a salaried service it might be to the advantage of general practitioners that the G.M S C had had no hand in it Dr J A **Pridham**, supporting the motion, pointed out that it was the Central Health Services Council that had omitted to consult the G M S C , this was another rebuff to the general practitioners

---

[1] See *Lancet* June 16 1951, p 1311

CONFINEMENTS IN HOSPITALS AND NURSING HOMES

The General Medical Services Committee was urged, on the proposition of Dr C R **Barrington** (Bromley), to secure the right of general practitioners to attend their patients who wished to be confined in hospital, and the provision of suitable accommodation for the purpose Dr **Wand** said he thought it likely that the Ministry would do all it could to help in this respect A resolution from Bristol, moved by Dr A G **Heron**, instructed council "to impress upon the Minister, as a matter of extreme urgency, the necessity of taking immediate measures to keep open efficient private maternity homes, thus adding to the efficiency and economy of the Service "

TRAINEE ASSISTANTS

Dr E E T **Taylor**, speaking to a motion from Northamptonshire against the present trainee assistant scheme, described the scheme as unpopular Dr H S **Howie Wood** (Isle of Wight) announced that the G.M.S C had set up a subcommittee to go into the whole question, and in the near future a communication would be sent to the local medical committees The motion was withdrawn

COMPLAINTS AGAINST DOCTORS

In a discussion on medical service committees and tribunals Dr H **Guy Dain** announced that the Ministry had agreed, as a first step, to issue to local executive councils a booklet on procedure in regard to complaints Dr J A **Gorsky** (Westminster and Holborn) pointed the contrast between the Medical Disciplinary Committee of the General Medical Council, under the new Medical Act, and the disciplinary procedure under the National Health Service There was the right of appeal to the Privy Council in respect of the former , in the latter the only appeal was to the Minister, who was a party Witnesses to the Medical Disciplinary Committee ran the risk of being had up for perjury , those before the tribunal did not Anyone removed from the Medical Register could be reinstated , nothing in the National Health Service Act said this could be done in regard to a practitioner removed from the list A doctor might be condemned to professional death for a lesser offence than the General Medical Council would remove his name from the Register for The meeting agreed to Dr Gorsky's motion, viewing with grave disquiet recent findings of certain medical service committees and the tribunal, demanding that the procedure should be overhauled, and reiterating the principle that there must be a right of appeal to the courts

Dr D **Thomson** (Dartford) deprecated any censure of a doctor by a local executive council, with its adverse publicity, "as a result of any and every trifling complaint " His motion, which was carried, further deplored that a doctor could not claim from the patient remuneration for loss of time and for the expenses of a locum tenens when the complaint was proved unjustified Dr **Wand** said that on the point of publicity the strongest representation had been made to the Ministry 'We feel it is thoroughly bad that trivial complaints should be made the subject of headlines in the press "

TOKEN PAYMENT FOR PRESCRIPTIONS

By a large majority the meeting rejected a proposal from Lincoln favouring a token payment for every prescription or similar service rendered by a practitioner Dr A M **Maiden** (Lincoln) suggested that such a payment would act as a deterrent to those who sought to exploit this so called free service No new principle was involved, because of the partial payments for teeth and spectacles It would mean a saving of national expenditure While making for economy it would not discourage any doctor from prescribing whatever he felt to be necessary for the patient's well being Old age pensioners and possibly school children and infants should be exempted, and could easily be identified The third category of exemptions—the chronic sick—presented a more difficult administrative problem, but one not incapable of solution Dr G O **Barber** (Mid-Essex), supporting the motion, said it was unfair for the Government now to say that if the family doctor wanted a little more money per head he must give fewer drugs Unless their pockets were touched, the public would do nothing about it Dr Barber described the "medicine bottle tasting parties " for which he had been the unwitting provider In the long winter evenings in the country there was not a great deal of night life, so anything which helped to pass the time was welcomed The technique of the medicine bottle tasting party was that the guests brought bottles of medicine and everyone had a taste "If a certain medicine is approved, the owner of the bottle is asked 'What were you complaining about to get that from the doctor ? ' " Dr **Annis Gillie** felt that a token payment would do much to restore the correct relationship of doctor and patient Dr **Dain** thought the token payment could easily be collected by a sixpenny stamp put on each prescription when it was presented to the chemist

Dr G **Smith** (Tower Hamlets) opposed the idea The token payment would act as a deterrent only to those in a low category economically Dr **Wand** pointed out that for many years the association had said that there should be no financial barrier between the patient and all necessary treatment The proposal was dangerously near politics Dr A **Beauchamp** (Birmingham) agreed. So did Dr H D **Findlay** (Birmingham), who pictured the politician pressing for a tax on prescriptions so as to reduce the drug bill, and at the next election saying, with crocodile tears, that it was the wicked doctors who had charged grandpa a shilling for his bottle of cough medicine and who had docked grannie's linctus, in order to raise his own capitation fee

MEMBERSHIP OF BOARDS AND COMMITTEES

A combined motion, which was carried, deplored "the tendency towards the replacing of doctors on regional hospital boards, boards of governors, and hospital management committees by laymen " It urged the Minister to reverse this tendency, to maintain adequate medical representation on all such bodies, and to take steps to overcome the difficulties existing between hospitals and general practitioners, such steps to include greater general practitioner representation at all levels in the National Health Service

ARRANGEMENTS FOR DOCTORS CALLED UP

Dr D F **Hutchinson** explained the scheme which the General Medical Services Committee had in mind with regard to practitioners who were called up in a national emergency He described it as being as simple and as fair as could be devised The net rate of remuneration on which the practitioner was assessed for superannuation purposes during the last quarter before he was called up would be taken as the basic rate, and his service pay would be made up to that amount throughout his service

GUY'S HOSPITAL

Reappointed Lord Cunliffe (chairman), Mrs E G M Barlas, J P, Mrs Iris Brook, **J M H. Campbell,** O B E, M C, F.R C.P, C J Conway, K C, Sir Patrick Ashley Cooper, LL B, Sir **William Kelsey Fry,** C B E, M C, M R C S, **O Gayer Morgan,** F R C S, F J O Prescott, L B Wimble

New members **Maxwell Ellis,** F R C S, **J C Hogg,** F.R C S

MOORFIELDS, WESTMINSTER AND CENTRAL EYE HOSPITAL

Reappointed Lord Luke, J P (chairman) E P Carter, O B E, A Gorman, Mrs A L Hollingsworth, J P, George Parker Jervis, Earl of Rothes, G C Stanley

New members **Frank Elliott,** F R C P, Harry Hutchinson

BETHLEM AND MAUDSLEY HOSPITALS

Reappointed **C P Blacker,** G M, M C, F R C P Mrs Kathleen Wilson, Alderman T E Morris, J P Mrs N C Runge, O B E, **E F Scowen,** F R C P

New members Lady Norman, J P, Lieut Colonel G J C Welch, O B E, M C, Alderman J C Maclean

ST JOHN'S HOSPITAL FOR DISEASES OF THE SKIN

Reappointed I A M Ellison Macartney (chairman), **G B Mitchell-Heggs,** O B E, F R C P, A D A Franklin, **S Cochrane Shanks,** F R C P Long, Miss Dorothy Fox, S I Salmon

HOSPITALS FOR DISEASES OF THE CHEST

Chairman Widdrington Stafford (for the rest of the period of his office—i e, to March 31, 1952)

Reappointed **R C Brock,** F R C S Sir John Gilmour, **J L. Livingstone,** F R C.P, H K Eaton Ostle, **V C Thompson,** F R C S Mrs Sarah Candy, Mrs Marguerite Watson three app[illegible]

New member **George Simon,** M D, outstanding

ROYAL NATIONAL ORTHOPÆDIC HOSPITAL

Reappointed Louis Fleischmann, O B E (chairman), Henry Floyd, C B, C B E, W Morgans, H C Willig, M Joan Wood

New member **Reginald Nassim,** F R C P, one appoint outstanding

NATIONAL HEART HOSPITAL

Reappointed J M Oakey, M C, J P (chairman), J Cohen, **T F Cotton,** F R C P, Sir **Francis Fraser,** F.R **B T Parsons-Smith,** F R C P

New member E G Gooch, C B E, M.P

ST PETER'S AND ST PAUL'S HOSPITALS

Reappointed L E D Bevan (chairman), A Farquhar, Sir Bertram Galer, J P, **A R. C Higham,** F J Russell Kelly, L G Mitchell Innes, H Short **Winsbury-White,** F R C S, one appointment outstandi

ROYAL CANCER HOSPITAL

Reappointed Sir Edward Cripps (chairman), **Ian Aird,** F R C S, **P E Thompson Hancock,** F R C P Jacob, Prof W V Mayneord, Mrs Noel Patrick Stanley, Claude S Harvey, **E A Carmichael,** F R C

QUEEN CHARLOTTE'S AND CHELSEA HOSPIT

Reappointed Sir Frederick Minter (chairman), Arthure, F.R C S, **Aubrey Goodwin,** O B E, F Viscountess Jowitt, E Musgrove, **Charles Newman,** A M Niven, Lady Ogilvie, Alan Sainsbury G W

EASTMAN DENTAL HOSPITAL

Reappointed Sir Frank Newnes (chairman) **R A Broderick,** D S O, M C, M B, F D S, Sir Willi Fry, C B E, M C, M R C S, B M Lindsay Fynn, G M W R Young, F D S

New member **G J Parfitt,** M R C S, L D S

Public Health

THE LEEDS TUBERCULOSIS SCH

An effective tuberculosis scheme depends [illegible] initiative of the regional hospital boards It is [illegible] to see how an energetic region is attacking the [illegible] and what progress has been made since the st[illegible] National Health Service, nearly three years ago

THE SURVEY

When the Leeds regional hospital board [illegible] a panel of doctors was convened by the board [illegible] the existing tuberculosis facilities in the re[illegible] to suggest, for the consideration of the Speciali[illegible] Committee, how to organise and develop the[illegible] full questionary was sent to hospital manage[illegible] mittees, and the information thus gained, sup[illegible] by the local knowledge of members of [illegible] assembled into a tabulated survey of [illegible] pensaries, their housing, equipment, and [illegible] numbers on their lists, and many other aspe[illegible] work

On July 5, 1948, there were 42 dispensar[illegible] in the region Only 1 of these, at Scar[illegible] in a general hospital, 3 others were att[illegible] toria and 1 other was in hospital pre[illegible] not all of these had X ray equipment [illegible] found that only one dispensary [illegible] had modern X ray equipment, [illegible] in varying degrees of obsole[illegible] 37 had no X ray equipme[illegible] were done in 24 [illegible] not even the [illegible] screening patients [illegible] dispensaries had been designed as such, [illegible] were said to have been adapted to their purp[illegible] th[illegible] of them were in converted dwell[illegible] in most cases they consisted of one or two office s and an unequipped examination room Some of were very oddly housed—one in the cloakrooms church hall, another in an old schoolhouse, another corrugated iron building, and another in a wooden hon But these standards of housing and equipment linics matched those in many other provincial s before the appointed day, and may have been stantially better than some

elatively few of the dispensaries had room for ansion—only 10 in all—and some of these were housed uildings which were in any case unsatisfactory It is eworthy that the clinics and dispensaries doing the gest amount of work were not necessarily the best ised Thus at 3 out of the 5 dispensaries housed in pitals attendances (of patients and contacts) were ow 500 a year, only one session a week—or even one onth—was held, and the numbers of new cases seen re negligible The Scarborough Hospital clinic, vever, had nearly 1250 attendances and about 55 v patients yearly, and the dispensary at Bradford, in onverted dwelling house, had an annual attendance some 7200, and a new case roll of 920 The largest tendance—then some 26,500 yearly—was at the New ggate dispensary, Leeds, housed in a building put up in 66 as the Leeds Public Dispensary, which dealt mainly th outpatients Other dispensaries with large attendances were at Hull, Sowerby Bridge, South irby, and Pontefract, only one of these ad X ray equipment, and that was out f date In two of the clinics—at Upper ill and Garforth—there was no proper ghting, and in one of them no running ater, and from one (Patrington) the atients had to travel 25 miles for neumothorax refills

PLANNING A POLICY

In making their proposals the panel did ot think in terms of tuberculosis alone, ut had in mind a chest service of much vider scope But they had also to bear in nind, when making short term recommendations about staffing and beds, that anatorium accommodation, experienced hest physicians, and nursing staff were ll scarce They based their estimates on he 200,000 unit of population adopted or the British Medical Association[1] As long term measure they believe there hould be 200 sanatorium beds, and 50 beds in general hospitals, for each such unit of population, and taking this as their standard they found that, even supposing ll the existing beds could be fully staffed up a steep hill [illegible] need a further 1000 pedal At the e[illegible]ment of pulmonary For[illegible]losis Moreover they judged that but it did no[illegible]tion of this size, 66 sessions I stooped an[illegible] weekly 12 at sanatoria, a rose [illegible]pitals, 24 at dispensaries, [illegible]patient departments, 12

My only Hom[illegible]ing and social welfare with medicine by[illegible]me for X ray exam do I find? A gent[illegible]s with the thoracic a fellow of a Royal [illegible]ies Allowing 11 there, wakes in Englan[illegible] doctor, such a [illegible] rabbit, and shoots it [illegible]fore need unit [illegible] I am a fellow of one, [illegible] 2 senior chest [illegible] one [illegible] you should physicians, and 1 registrar [illegible] throom

In rearranging the dispensaries the panel remembered that the diagnostic service must keep in close touch with the aftercare service, and so proposed administrative arrangements which fitted with the county, county-borough, and sanitary district boundaries Throughout they had in mind the convenience of patients and the means they had of getting to the clinics. They were anxious, wherever possible, to get rid of the unequipped visiting station, and to link up each chest centre with the outpatient department of a general hospital, and this has been achieved to a very large extent In 18 cases it has been possible either to move dispensaries into hospitals, or to arrange that they shall be moved there at an early date Already 7 new screening sets have been installed, and 2 major X ray sets and 4 more screening sets are to be delivered this year A new X ray department has been set up at Goole, in the hospital which is now to house the Goole chest clinic. Of the unequipped stations, 5 have either been closed or are to be closed as soon as new plans in the area are complete, 11 more are being retained as visiting stations for the convenience of patients, but 5 of the busiest of these are to be transferred into hospitals as soon as arrangements can be made The two maps show the former and the new distribution of clinics and the X ray facilities in the various areas A few examples will show clearly the kind of thing that has happened
